byte[] channelUriInBytes = System.Text.Encoding.UTF8.GetBytes("ChannelUri="
+ channel.Uri);

// Write the channel URI to the request stream.
Stream requestStream = await webRequest.GetRequestStreamAsync();
requestStream.Write(channelUriInBytes, 0, channelUriInBytes.Length);

try
{
    // Get the response from the server.
    WebResponse response = await webRequest.GetResponseAsync();
    StreamReader requestReader = new
StreamReader(response.GetResponseStream());
    String webResponse = requestReader.ReadToEnd();
}

catch (Exception ex)
{
    // Could not send channel URI to server.
}
```

Remarks

Requesting channels

You should request a new channel each time your app is invoked, by using the following logic:

1. Request a channel.
2. Compare the new channel with your previous channel. If the channel is the same, you don't need to take any further action. Note that this requires your app to store the channel locally each time the app successfully sends it to your service, so that you have the channel to compare against later.
3. If the channel has changed, send the new channel to your web service. Include error handling logic that always sends a new channel in the following cases:

    - Your app has never sent a channel to the web service before.
    - Your app's last attempt to send the channel to the web service was not successful.

Different calls to the CreatePushNotificationChannelForApplicationAsync method do not always return a different channel. If the channel has not changed since the last call, your app should conserve effort and Internet traffic by not resending that same channel to your service. An app can have multiple valid channel URIs at the same time. Because

each unique channel remains valid until it expires, there is no harm in requesting a new channel because it does not affect the expiration time of any previous channels.

By requesting a new channel each time your app is invoked, you maximize your chances of always having access to a valid channel. This is particularly important if it is vital to your tile or toast scenario that content always be live. If you are concerned that a user might not run your app more than once every 30 days, you can implement a background task to execute your channel request code on a regular basis.

Handling errors in channel requests

The call to the **CreatePushNotificationChannelForApplicationAsync** method can fail if the Internet is not available. To handle this, add retry logic to the code shown in step 2. We recommend three attempts with a 10-second delay between each unsuccessful attempt. If all three attempts fail, your app should wait until the next time the user launches it to try again.

Closing channels

Your app can immediately stop the delivery of notifications on all channels by calling the **PushNotificationChannel.Close** method. While it will not be common for your app to do so, there might be certain scenarios in which you want to stop all notification delivery to your app. For instance, if your app has the concept of user accounts and a user logs out of that app, it is reasonable to expect that the tile no longer shows that user's personal information. To successfully clear the tile of content and stop the delivery of notifications, you should do the following:

1. Stop all tile updates by calling the **PushNotificationChannel.Close** method on any of your notification channels that are delivering tile, toast, badge or raw notifications to a user. Calling the **Close** method ensures that no further notifications for that user can be delivered to the client.
2. Clear the contents of the tile by calling the **TileUpdater.Clear** method to remove the previous user's data from the tile.

Push notification service request and response headers (Windows Runtime apps)

Article • 05/03/2024

This topic describes the service-to-service web APIs and protocols required to send a push notification.

See the Windows Push Notification Services (WNS) overview for a conceptual discussion of push notification and WNS concepts, requirements, and operation.

Requesting and receiving an access token

This section describes the request and response parameters involved when you authenticate with the WNS.

Access token request

An HTTP request is sent to WNS to authenticate the cloud service and retrieve an access token in return. The request is issued to `https://login.live.com/accesstoken.srf` using Secure Sockets Layer (SSL).

Access token request parameters

The cloud service submits these required parameters in the HTTP request body, using the "application/x-www-form-urlencoded" format. You must ensure that all parameters are URL encoded.

Expand table

Parameter	Required	Description
grant_type	TRUE	Must be set to `client_credentials`.
client_id	TRUE	Package security identifier (SID) for your cloud service as assigned when you registered your app with the Microsoft Store.
client_secret	TRUE	Secret key for your cloud service as assigned when you registered your app with the Microsoft Store.

Parameter	Required	Description
scope	TRUE	Must be set to `notify.windows.com`

Access token response

WNS authenticates the cloud service and, if successful, responds with a "200 OK", including the access token. Otherwise, WNS responds with an appropriate HTTP error code as described in the OAuth 2.0 protocol draft.

Access token response parameters

An access token is returned in the HTTP response if the cloud service successfully authenticated. This access token can be used in notification requests until it expires. The HTTP response uses the "application/json" media type.

Expand table

Parameter	Required	Description
access_token	TRUE	The access token that the cloud service will use when it sends a notification.
token_type	FALSE	Always returned as `bearer`.

Response code

Expand table

HTTP response code	Description
200 OK	The request was successful.
400 Bad Request	The authentication failed. See the OAuth draft Request for Comments (RFC) for response parameters.

Example

The following shows an example of a successful authentication response:

```
JSON
```

```
HTTP/1.1 200 OK
Cache-Control: no-store
Content-Length: 422
Content-Type: application/json

{
    "access_token":"EgAcAQMAAAAALYAAY/c+Huwi3Fv4Ck10UrKNmtxRO6Njk2MgA=",
    "token_type":"bearer",
    "expires_in": 86400
}
```

Sending a notification request and receiving a response

This section describes the headers involved in an HTTP request to WNS to deliver a notification and those involved in the reply.

- Send notification request
- Send notification response
- Unsupported HTTP features

Send notification request

When sending a notification request, the calling app makes an HTTP request over SSL, addressed to the channel Uniform Resource Identifier (URI). "Content-Length" is a standard HTTP header that must be specified in the request. All other standard headers are either optional or not supported.

In addition, the custom request headers listed here can be used in the notification request. Some headers are required while others are optional.

Request parameters

Expand table

Header name	Required	Description
Authorization	TRUE	Standard HTTP authorization header used to authenticate your notification request. Your cloud service provides its access token in this header.
Content-Type	TRUE	Standard HTTP authorization header. For toast, tile, and badge notifications, this header must be set to `text/xml`. For raw

Header name	Required	Description
		notifications, this header must be set to `application/octet-stream`.
Content-Length	TRUE	Standard HTTP authorization header to denote the size of the request payload.
X-WNS-Type	TRUE	Defines the notification type in the payload: tile, toast, badge, or raw.
X-WNS-Cache-Policy	FALSE	Enables or disables notification caching. This header applies only to tile, badge, and raw notifications.
X-WNS-RequestForStatus	FALSE	Requests device status and WNS connection status in the notification response.
X-WNS-Tag	FALSE	String used to provide a notification with an identifying label, used for tiles that support the notification queue. This header applies only to tile notifications.
X-WNS-TTL	FALSE	Integer value, expressed in seconds, that specifies the time to live (TTL).
MS-CV	FALSE	Correlation Vector value used for your request.

Important notes

- Content-Length and Content-Type are the only standard HTTP headers that are included in the notification delivered to the client, regardless of whether other standard headers were included in the request.
- All other standard HTTP headers are either ignored or return an error if the functionality is not supported.
- Starting in February 2023, WNS will cache only one tile notification when the device is offline.

Authorization

The authorization header is used to specify the credentials of the calling party, following the OAuth 2.0 authorization method for bearer tokens.

The syntax consists of a string literal "Bearer", followed by a space, followed by your access token. This access token is retrieved by issuing the access token request described above. The same access token can be used on subsequent notification requests until it expires.

This header is required.

```
JSON

Authorization: Bearer <access-token>
```

X-WNS-Type

These are the notification types supported by WNS. This header indicates the type of notification and how WNS should handle it. After the notification reaches the client, the actual payload is validated against this specified type. This header is required.

```
JSON

X-WNS-Type: wns/toast | wns/badge | wns/tile | wns/raw
```

Expand table

Value	Description
wns/badge	A notification to create a badge overlay on the tile. The Content-Type header included in the notification request must be set to `text/xml`.
wns/tile	A notification to update the tile content. The Content-Type header included in the notification request must be set to `text/xml`.
wns/toast	A notification to raise a toast on the client. The Content-Type header included in the notification request must be set to `text/xml`.
wns/raw	A notification which can contain a custom payload and is delivered directly to the app. The Content-Type header included in the notification request must be set to `application/octet-stream`.

X-WNS-Cache-Policy

When the notification target device is offline, WNS will cache one badge, one tile, and one toast notification for each channel URI. By default, raw notifications are not cached, but if raw notification caching is enabled, one raw notification is cached. Items are not held in the cache indefinitely and will be dropped after a reasonable period of time. Otherwise, the cached content is delivered when the device next comes online.

```
JSON
```

```
X-WNS-Cache-Policy: cache | no-cache
```

Expand table

Value	Description
cache	Default. Notifications will be cached if the user is offline. This is the default setting for tile and badge notifications.
no-cache	The notification will not be cached if the user is offline. This is the default setting for raw notifications.

X-WNS-RequestForStatus

Specifies whether the response should include the device status and WNS connection status. This header is optional.

JSON

```
X-WNS-RequestForStatus: true | false
```

Expand table

Value	Description
true	Return the device status and notification status in the response.
false	Default. Do not return the device status and notification status.

X-WNS-Tag

Assigns a tag label to a notification. The tag is used in the replacement policy of the tile in the notification queue when the app has opted for notification cycling. If a notification with this tag already exists in the queue, a new notification with the same tag takes its place.

> **Note**
>
> This header is optional and used only when sending tile notifications.

JSON

```
X-WNS-Tag: <string value>
```

Expand table

Value	Description
string value	An alphanumeric string of no more than 16 characters.

X-WNS-TTL

Specifies the TTL (expiration time) for a notification. This is not typically needed, but can be used if you want to ensure that your notifications are not displayed later than a certain time. The TTL is specified in seconds and is relative to the time that WNS receives the request. When a TTL is specified, the device will not display the notification after that time. Note that this could result in the notification never being shown at all if the TTL is too short. In general, an expiration time will be measured in at least minutes.

This header is optional. If no value is specified, the notification does not expire and will be replaced under the normal notification replacement scheme.

X-WNS-TTL: `<integer value>`

Expand table

Value	Description
integer value	The life span of the notification, in seconds, after WNS receives the request.

X-WNS-SuppressPopup

> **Note**
>
> For Windows Phone Store apps, you have the option to suppress a toast notification's UI, instead sending the notification directly to the action center. This lets your notification be delivered silently, a potentially superior option for less urgent notifications. This header is optional and only used on Windows Phone channels. If you include this header on a Windows channel, your notification will be dropped and you will receive an error response from WNS.

X-WNS-SuppressPopup: true | false

Expand table

Value	Description
true	Send the toast notification directly to the action center; do not raise the toast UI.
false	Default. Raise the toast UI as well as adding the notification to the action center.

X-WNS-Group

> **Note**
>
> The action center for Windows Phone Store apps can display multiple toast notifications with the same tag only if they are labelled as belonging to different groups. For example, consider a recipe book app. Each recipe would be identified by a tag. A toast that contains a comment on that recipe would have the recipe's tag, but a comment group label. A toast that contains a rating for that recipe would again have that recipe's tag, but would have a rating group label. Those different group labels would allow both toast notifications to be shown at once in the action center. This header is optional.

X-WNS-Group: `<string value>`

Expand table

Value	Description
string value	An alphanumeric string of no more than 16 characters.

X-WNS-Match

> **Note**
>
> Used with the HTTP DELETE method to remove a specific toast, a set of toasts (by either tag or group), or all toasts from the action center for Windows Phone Store apps. This header can specify a group, a tag, or both. This header is required in an HTTP DELETE notification request. Any payload included with this notification request is ignored.

X-WNS-Match: type:wns/toast;group=`<string value>`;tag=`<string value>` | type:wns/toast;group=`<string value>` | type:wns/toast;tag=`<string value>` | type:wns/toast;all

Expand table

Value	Description
type:wns/toast;group=`<string value>`;tag=`<string value>`	Remove a single notification labelled with both the specified tag and group.
type:wns/toast;group=`<string value>`	Remove all notifications labelled with the specified group.
type:wns/toast;tag=`<string value>`	Remove all notifications labelled with the specified tag.
type:wns/toast;all	Clear all of your app's notifications from the action center.

Send notification response

After WNS processes the notification request, it sends an HTTP message in response. This section discusses the parameters and headers that can be found in that response.

Response parameters

Expand table

Header name	Required	Description
X-WNS-Debug-Trace	FALSE	Debugging information that should be logged to help troubleshoot issues when reporting a problem.
X-WNS-DeviceConnectionStatus	FALSE	The device status, returned only if requested in the notification request through the X-WNS-RequestForStatus header.
X-WNS-Error-Description	FALSE	A human-readable error string that should be logged to help with debugging.
X-WNS-Msg-ID	FALSE	A unique identifier for the notification, used for debugging purposes. When reporting a problem, this information should be logged to help in troubleshooting.

Header name	Required	Description
X-WNS-Status	FALSE	Indicates whether WNS successfully received and processed the notification. When reporting a problem, this information should be logged to help in troubleshooting.
MS-CV	FALSE	Debugging information that should be logged to help troubleshoot issues when reporting a problem.

X-WNS-Debug-Trace

This header returns useful debugging information as a string. We recommend that this header be logged to help developers debug issues. This header, together with the X-WNS-Msg-ID header and MS-CV, are required when reporting an issue to WNS.

X-WNS-Debug-Trace: `<string value>`

Expand table

Value	Description
string value	An alphanumeric string.

X-WNS-DeviceConnectionStatus

This header returns the device status to the calling application, if requested in the X-WNS-RequestForStatus header of the notification request.

X-WNS-DeviceConnectionStatus: connected | disconnected | tempdisconnected

Expand table

Value	Description
connected	The device is online and connected to WNS.
disconnected	The device is offline and not connected to WNS.
tempconnected (deprecated)	The device temporarily lost connection to WNS, for instance when a 3G connection is dropped or the wireless switch on a laptop is thrown. It is seen by the Notification Client Platform as a temporary interruption rather than an intentional disconnection.

X-WNS-Error-Description

This header provides a human-readable error string that should be logged to help with debugging.

X-WNS-Error-Description: `<string value>`

Expand table

Value	Description
string value	An alphanumeric string.

X-WNS-Msg-ID

This header is used to provide the caller with an identifier for the notification. We recommended that this header be logged to help debug issues. This header, together with the X-WNS-Debug-Trace and MS-CV, are required when reporting an issue to WNS.

X-WNS-Msg-ID: `<string value>`

Expand table

Value	Description
string value	An alphanumeric string of no more than 16 characters.

X-WNS-Status

This header describes how WNS handled the notification request. This can be used rather than interpreting response codes as success or failure.

X-WNS-Status: received | dropped | channelthrottled

Expand table

Value	Description
received	The notification was received and processed by WNS. **Note:**This does not guarantee that the device received the notification.
dropped	The notification was explicitly dropped because of an error or because the client has explicitly rejected these notifications. Toast notifications will also be

Value	Description
	dropped if the device is offline.
channelthrottled	The notification was dropped because the app server exceeded the rate limit for this specific channel.

MS-CV

This header provides a Correlation Vector related to the request which is primarily used for debugging. If a CV is provided as part of the request then WNS will use this value, else WNS will generate and respond back with a CV. This header, together with the X-WNS-Debug-Trace and X-WNS-Msg-ID header, are required when reporting an issue to WNS.

> **Important**
>
> Please generate a new CV for each push notification request if you are providing your own CV.

MS-CV: `<string value>`

Expand table

Value	Description
string value	Follows the Correlation Vector standard

Response codes

Each HTTP message contains one of these response codes. WNS recommends that developers log the response code for use in debugging. When developers report an issue to WNS, they are required to provide response codes and header information.

Expand table

HTTP response code	Description	Recommended action
200 OK	The notification was accepted by WNS.	None required.

HTTP response code	Description	Recommended action
400 Bad Request	One or more headers were specified incorrectly or conflict with another header.	Log the details of your request. Inspect your request and compare against this documentation.
401 Unauthorized	The cloud service did not present a valid authentication ticket. The OAuth ticket may be invalid.	Request a valid access token by authenticating your cloud service using the access token request.
403 Forbidden	The cloud service is not authorized to send a notification to this URI even though they are authenticated.	The access token provided in the request does not match the credentials of the app that requested the channel URI. Ensure that your package name in your app's manifest matches the cloud service credentials given to your app in the Dashboard.
404 Not Found	The channel URI is not valid or is not recognized by WNS.	Log the details of your request. Do not send further notifications to this channel; notifications to this address will fail.
405 Method Not Allowed	Invalid method (GET, CREATE); only POST (Windows or Windows Phone) or DELETE (Windows Phone only) is allowed.	Log the details of your request. Switch to using HTTP POST.
406 Not Acceptable	The cloud service exceeded its throttle limit.	Please send your request after the Retry-After header value in the response
410 Gone	The channel expired.	Log the details of your request. Do not send further notifications to this channel. Have your app request a new channel URI.
410 Domain Blocked	The sending domain has been blocked by WNS.	Do not send further notifications to this channel. The sending domain has been blocked by WNS for abusing push notifications.
413 Request Entity Too Large	The notification payload exceeds the 5000 byte size limit.	Log the details of your request. Inspect the payload to ensure it is within the size limitations.
500 Internal Server Error	An internal failure caused notification delivery to fail.	Log the details of your request. Report this issue through the developer forums.
503 Service Unavailable	The server is currently unavailable.	Log the details of your request. Report this issue through the developer forums. If the Retry-After header is observed then please send your

HTTP response code	Description	Recommended action
		request after the Retry-After header value in the response.

Unsupported HTTP features

The WNS Web Interface supports HTTP 1.1 but does not support the following features:

- Chunking
- Pipelining (POST is not idempotent)
- Although supported, developers should disable Expect-100 as that introduces latency when sending a notification.

Troubleshooting WNS push notifications

Article • 10/25/2021

This topic discusses initial troubleshooting steps you should take when you encounter problems with tile, toast, and badge notifications, including the various notification methods: local, push, periodic, and scheduled notifications.

Troubleshooting specific errors

This section addresses some common errors you might encounter while working with push notifications.

- Check your event logs
- Push notification receives a "200 OK" response, but does not display
- Push notification returns a code other than "200 OK"
- Errors when attempting to create a push notification channel

Check your event logs

If tile or toast push notifications are not displaying as expected, have a look at the event logs.

- **If the notification is received but not shown**: Launch the Event Viewer and examine the *Microsoft-Windows-TWinUI/Operational* log under Applications and Services\Microsoft\Windows\Apps.
- **If the notification is not received at all**: Launch the Event Viewer and examine the Operational log under Applications and Services\Microsoft\Windows\PushNotifications-Platform.

Push notification receives a "200 OK" response, but does not display

If Windows Push Notification Services (WNS) returns a "200 OK" response, then it will deliver the notification to the client if the client is online. If you have verified that the client is online but not displaying the notification, walk through these steps:

- **Cause**: XML errors in the notification content.

  Fix: Verify the basic XML syntax and make sure that your XML is complete and correct. Some common points of failure in the XML content include the following:

    - Case sensitivity. Tag names, attribute names, and attribute values are all case sensitive. Be sure that your XML has the correct casing.
    - A **binding** element must be provided for each supported tile format. You should provide a **binding** element for each of the tile sizes you support in each notification you send.
    - Text strings should not contain reserved XML characters. For example, you cannot italicize tile or toast strings by including and tags. If you intend to show the literal characters "", they should be properly escaped. For more information on escape characters in XML, see XML Character Entities and XAML.
    - The values supplied for the *lang* attributes must conform to the ITEF BCP 47 specification.
    - XML strings sent through push notifications should use the UTF-8 encoding.
    - If you include an **image** element in your XML payload with a non-empty src attribute, you must be sure to include a reference to a valid image or the notification will be dropped.

- **Cause**: Improper use of push notification API parameters

  Fix: See the API documentation in the **Windows.Networking.PushNotifications** namespace for specifics.

- **Cause**: Header type does not match notification content. If the X-WNS-Type header is not set to a value—tile, badge, or toast—that corresponds to the notification template specified in the payload, the notification will not be displayed. This mismatch will cause an error on the client and the notification will be dropped.

  Fix: Refer to Push notification service request and response headers to ensure that your app server is using the correct value for the X-WNS-Type header.

- **Cause**: The time to live (TTL) value, set in the X-WNS-TTL header, is too small.

  Fix: Provide a larger TTL value, being aware that the value is given in seconds.

If you still do not see your notification displayed after addressing the items in the previous steps, see the troubleshooting steps for local notifications in the Local tile notification is not displayed section of this topic for further suggestions.

Push notification returns a code other than "200 OK"

If WNS doesn't return "200 OK", your notification will not be delivered to the client. If the return code is in the 400s, then you, as a developer, should be able to fix the issue.

> **Note**
>
> For errors not specifically listed here, see **COM Error Codes (WPN, MBN, P2P, Bluetooth)**.

- Notification request returns "400 Bad Request"
- Notification request returns "401 Unauthorized"
- Notification request returns "401 Unauthorized", token is expired
- Notification request returns "403 Forbidden"
- Notification request returns "404 Not Found"
- Notification request returns "406 Not Acceptable"
- Notification request returns "410 Gone"

Notification request returns "400 Bad Request"

- **Cause**: The use of one or more WNS headers could be incorrect or the HTTP request was invalid.

  Fix: Refer to Push notification service request and response headers to ensure that your app server is using all custom headers as described.

Notification request returns "401 Unauthorized"

- **Cause**: Your app server must use the correct Package Security Identifier (Package SID) and secret key given to you when registered your app. If you have recently changed your secret key in the Windows Store Dashboard, you will also need to update your app server.

  Fix: Visit the Windows StoreDashboard to verify your Package SID and secret.

Notification request returns "401 Unauthorized", token is expired

- **Cause**: An access token has a finite lifetime. If you send a notification with an expired access token, your app server's credentials are invalid and the notification cannot be sent.

  Fix: Request a new access token from WNS by authenticating with WNS using your Package Security Identifier (Package SID) and secret key. For more information, see the Windows Push Notification Services (WNS) overview

Notification request returns "403 Forbidden"

- **Cause**: This error occurs when the access token that you presented does not match the credentials required to send notifications to the corresponding channel URL. Every app must be registered with the Windows Store to receive credentials for its app server. For each app, only the credentials provided by the Windows Store can be used to send notifications to that app and they can be used only for that particular app.

  Fix: Log into the Windows Store Dashboard with your developer account. Select your app and click "Advanced Features" -> "Manage your cloud service settings". Select "Identifying your app" to read instructions on updating your app manifest to match your cloud service credentials.

Notification request returns "404 Not Found"

- **Cause**: This error typically means that the channel URL is not formed correctly. The channel URL must never be tampered with or modified when you send a notification to WNS. The channel URL should always be treated as an opaque string—you never need to examine or even know its content.

  Fix: Verify that your code is not modifying the channel URL either by changing one or more of its characters or changing its encoding.

Notification request returns "406 Not Acceptable"

- **Cause**: WNS has protective policies in place to prevent malicious apps from negatively impacting the service for other users and developers. An excessive number of notifications in too short a time period can result in WNS explicitly dropping notifications.

  Fix: Review your notification frequency to see if it can be decreased or optimized to produce a better user experience.

Notification request returns "410 Gone"

- **Cause**: The channel URL has expired. No further notifications can be sent until your app runs and requests a new channel URL.

  Fix: Your Windows Store app should request a channel URL each time it is launched. The channel URL that it is assigned is not guaranteed to remain the

same. If the URL has changed, the client should update the information on its cloud server.

Errors when attempting to create a push notification channel

- Creating a notification channel results in an ERROR_NO_NETWORK error
- Creating a notification channel results in an WPN_E_CLOUD_INCAPABLE error
- Creating a notification channel results in an WPN_E_INVALID_APP error

> ⓘ **Note**
>
> For errors not specifically listed here, see **COM Error Codes (WPN, MBN, P2P, Bluetooth)**.

Creating a notification channel results in an ERROR_NO_NETWORK error

- **Cause**: WNS requires an Internet connection to create a notification channel.

  Fix: Check your Internet connectivity.

Creating a notification channel results in an WPN_E_CLOUD_INCAPABLE error

- **Cause**: Your app has not declared the Internet capability in its app manifest (package.appxmanifest).

  Fix: Ensure that your app manifest has declared Internet capability. In the Visual Studio manifest editor, you will find this option under the Capabilities tab as **Internet (Client)**. For more information, see **Capabilities**.

Creating a notification channel results in an WPN_E_INVALID_APP error

- **Cause**: Your app must use a valid package name. If you have not received one yet, you can get it through the Windows Store portal under "Advanced Features".

  Fix: For details on retrieving a Package Security Identifier (PKSID) for your Windows Store app, see Windows Push Notification Services (WNS) overview.

Reporting an issue

If you have tried the solutions suggested in this topic and have not resolved your issue, post a message on the Microsoft forums to discuss it with both Microsoft developers and other interested parties.

For push notifications, in addition to a description of the problem, you might be asked to provide your channel URL and an example of the response you received from WNS, including both the HTTP error codes and HTTP headers. There are specific headers that your app server should be logging when reporting an issue. For more information, see Push notification service request and response headers.

Raw notification overview

Article • 03/17/2023

Raw notifications are short, general purpose push notifications. They are strictly instructional and do not include a UI component. As with other push notifications, the Windows Push Notification Services (WNS) feature delivers raw notifications from your cloud service to your app.

You can use raw notifications for a variety of purposes, including to trigger your app to run a background task if the user has given the app permission to do so. By using WNS to communicate with your app, you can avoid the processing overhead of creating persistent socket connections, sending HTTP GET messages, and other service-to-app connections.

> **Important**
>
> To understand raw notifications, it's best to be familiar with the concepts discussed in the Windows Push Notification Services (WNS) overview.

As with toast, tile, and badge push notifications, a raw notification is pushed from your app's cloud service over an assigned channel Uniform Resource Identifier (URI) to WNS. WNS, in turn, delivers the notification to the device and user account associated with that channel. Unlike other push notifications, raw notifications don't have a specified format. The content of the payload is entirely app-defined.

As an illustration of an app that could benefit from raw notifications, let's look at a theoretical document collaboration app. Consider two users who are editing the same document at the same time. The cloud service, which hosts the shared document, could use raw notifications to notify each user when changes are made by the other user. The raw notifications would not necessarily contain the changes to the document, but instead would signal each user's copy of the app to contact the central location and sync the available changes. By using raw notifications, the app and its cloud service can save the overhead of maintaining persistent connections the entire time the document is open.

How raw notifications work

All raw notifications are push notifications. Therefore, the setup required to send and receive push notifications applies to raw notifications as well:

- You must have a valid WNS channel to send raw notifications. For more information about acquiring a push notification channel, see How to request, create, and save a notification channel.
- You must include the **Internet** capability in your app's manifest. In the Microsoft Visual Studio manifest editor, you will find this option under the **Capabilities** tab as **Internet (Client)**. For more information, see **Capabilities**.

The body of the notification is in an app-defined format. The client receives the data as a null-terminated string (**HSTRING**) that only needs to be understood by the app.

If the client is offline, raw notifications will be cached by WNS only if the X-WNS-Cache-Policy header is included in the notification. However, only one raw notification will be cached and delivered once the device comes back online.

There are only three possible paths for a raw notification to take on the client: they will be delivered to your running app through a notification delivery event, sent to a background task, or dropped. Therefore, if the client is offline and WNS attempts to deliver a raw notification, the notification is dropped.

Creating a raw notification

Sending a raw notification is similar to sending a tile, toast, or badge push notification, with these differences:

- The HTTP Content-Type header must be set to "application/octet-stream".
- The HTTP X-WNS-Type header must be set to "wns/raw".
- The notification body can contain any string payload smaller than 5 KB in size, but must not be an empty string.

Raw notifications are intended to be used as short messages that trigger your app to take an action, such as to directly contact the service to sync a larger amount of data or to make a local state modification based on the notification content. Note that WNS push notifications cannot be guaranteed to be delivered, so your app and cloud service must account for the possibility that the raw notification might not reach the client, such as when the client is offline.

For more information on sending push notifications, see Quickstart: Sending a push notification.

Receiving a raw notification

There are two avenues through which your app can be receive raw notifications:

- Through notification delivery events while your application is running.
- Through background tasks triggered by the raw notification if your app is enabled to run background tasks.

An app can use both mechanisms to receive raw notifications. If an app implements both the notification delivery event handler and background tasks that are triggered by raw notifications, the notification delivery event will take priority when the app is running.

- If the app is running, the notification delivery event will take priority over the background task and the app will have the first opportunity to process the notification.
- The notification delivery event handler can specify, by setting the event's **PushNotificationReceivedEventArgs.Cancel** property to **true**, that the raw notification should not be passed to its background task once the handler exits. If the **Cancel** property is set to **false** or is not set (the default value is **false**), the raw notification will trigger the background task after the notification delivery event handler has done its work.

Notification delivery events

Your app can use a notification delivery event (**PushNotificationReceived**) to receive raw notifications while the app is in use. When the cloud service sends a raw notification, the running app can receive it by handling the notification delivery event on the channel URI.

If your app is not running and does not use background tasks), any raw notification sent to that app is dropped by WNS on receipt. To avoid wasting your cloud service's resources, you should consider implementing logic on the service to track whether the app is active. There are two sources of this information: an app can explicitly tell the service that it's ready to start receiving notifications, and WNS can tell the service when to stop.

- **The app notifies the cloud service**: The app can contact its service to let it know that the app is running in the foreground. The disadvantage of this approach is that the app can end up contacting your service very frequently. However, it has the advantage that the service will always know when the app is ready to receive incoming raw notifications. Another advantage is that when the app contacts its

service, the service then knows to send raw notifications to the specific instance of that app rather than broadcast.

- **The cloud service responds to WNS response messages** : Your app service can use the X-WNS-NotificationStatus and X-WNS-DeviceConnectionStatus information returned by WNS to determine when to stop sending raw notifications to the app. When your service sends a notification to a channel as an HTTP POST, it can receive one of these messages in the response:
  - **X-WNS-NotificationStatus: dropped**: This indicates that the notification was not received by the client. It's a safe assumption that the **dropped** response is caused by your app no longer being in the foreground on the user's device.
  - **X-WNS-DeviceConnectionStatus: disconnected** or **X-WNS-DeviceConnectionStatus: tempconnected**: This indicates that the Windows client no longer has a connection to WNS. Note that to receive this message from WNS, you have to ask for it by setting the X-WNS-RequestForStatus header in the notification's HTTP POST.

  Your app's cloud service can use the information in these status messages to cease communication attempts through raw notifications. The service can resume sending raw notifications once it is contacted by the app, when the app switches back into the foreground.

  Note that you should not rely on X-WNS-NotificationStatus to determine whether the notification was successfully delivered to the client.

  For more information, see Push notification service request and response headers

Background tasks triggered by raw notifications

> **ⓘ Important**
>
> Before using raw notification background tasks, an app must be granted background access via **BackgroundExecutionManager.RequestAccessAsync**.

Your background task must be registered with a **PushNotificationTrigger**. If it is not registered, the task will not run when a raw notification is received.

A background task that is triggered by a raw notification enables your app's cloud service to contact your app, even when the app is not running (though it might trigger it to run). This happens without the app having to maintain a continuous connection. Raw

notifications are the only notification type that can trigger background tasks. However, while toast, tile, and badge push notifications cannot trigger background tasks, background tasks triggered by raw notifications can update tiles and invoke toast notifications through local API calls.

As an illustration of how background tasks that are triggered by raw notifications work, let's consider an app used to read e-books. First, a user purchases a book online, possibly on another device. In response, the app's cloud service can send a raw notification to each of the user's devices, with a payload that states that the book was purchased and the app should download it. The app then directly contacts the app's cloud service to begin a background download of the new book so that later, when the user launches the app, the book is already there and ready for reading.

To use a raw notification to trigger a background task, your app must:

1. Request permission to run tasks in the background (which the user can revoke at any time) by using **BackgroundExecutionManager.RequestAccessAsync**.
2. Implement the background task. For more information, see Support your app with background tasks

Your background task is then invoked in response to the **PushNotificationTrigger**, each time a raw notification is received for your app. Your background task interprets the raw notification's app-specific payload and acts on it.

For each app, only one background task can run at a time. If a background task is triggered for an app for which a background task is already running, the first background task must complete before the new one is run.

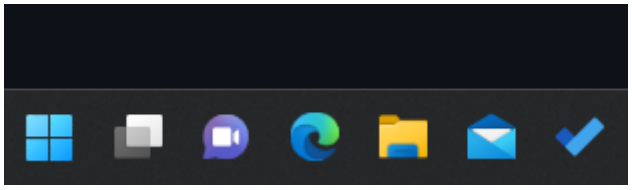
Pin your app to the taskbar

Article • 02/27/2024

Now you can programmatically request users to pin your Win32 or UWP app to the taskbar, similar to how you can pin your app to the Start menu. And you can check whether your app is currently pinned, and whether the taskbar allows pinning.



> **ⓘ Important**
>
> **Requires Fall Creators Update**: You must target SDK 16299 and be running build 16299 or later to use the taskbar APIs.

> **Important APIs**: TaskbarManager class

When should you ask the user to pin your app to the taskbar?

The TaskbarManager class lets you ask the user to pin your app to the taskbar; the user must approve the request. You put a lot of effort into building a stellar app, and now you have the opportunity to ask the user to pin it to taskbar. But before we dive into the code, here are some things to keep in mind as you are designing your experience:

- **Do** craft a non-disruptive and easily dismissible UX in your app with a clear call to action. Avoid using dialogs and flyouts for this purpose. Accessible pinning icons or similar UX is recommended but not required.
- **Do** ensure your app has value to the user before asking the user to pin it.
- **Don't** ask a user to pin your app if the tile is already pinned or the device doesn't support it. (This article explains how to determine whether pinning is supported.)
- **Don't** repeatedly ask the user to pin your app (they will probably get annoyed).
- **Don't** call the pin API without explicit user interaction or when your app is minimized/not open. Your app must be in the foreground for the process to work.
- **Don't** use installers to call the API.

Limited Access Feature (LAF) approval

> **ⓘ Important**
>
> The Taskbar Pinning is a Limited Access Feature (see LimitedAccessFeatures class). For more information or to request an unlock token, please use the LAF Access Token Request Form.

1. Check whether the required APIs exist

UWP

If your app supports older versions of Windows 10, you need to check whether the `TaskbarManager` class is available. You can use the ApiInformation.IsTypePresent method to perform this check. If the `TaskbarManager` class isn't available, avoid executing any calls to the APIs.

C#

```
if (ApiInformation.IsTypePresent("Windows.UI.Shell.TaskbarManager"))
{
    // Taskbar APIs exist!
}

else
{
    // Older version of Windows, no taskbar APIs
}
```

Win32

If you want to use `TaskbarManager` from your WIn32 desktop app, then you'll need to check whether desktop app support is present. You can look for the `ITaskbarManagerDesktopAppSupportStatics` marker interface on the `TaskbarManager` activation factory to perform this check. If this interface is not available, then you won't be able to use `TaskbarManager` from your desktop app.

C++

```
if
(winrt::try_get_activation_factory<winrt::Windows::UI::Shell::TaskbarManager
, winrt::Windows::UI::Shell::ITaskbarManagerDesktopAppSupportStatics>())
{
    // TaskbarManager desktop app support is available.
```

```
}
else
{
    // TaskbarManager desktop app support is not available.
}
```

2. Check whether taskbar is present and allows pinning

Windows apps can run on a wide variety of devices; not all of them support the taskbar. Right now, only Desktop devices support the taskbar. Additionally, apps may request pinning, but pinning may not be allowed at any given time. It is suggested that apps check whether pinning is allowed before UX is surfaced to prevent confusing users.

Even if the taskbar is available, a group policy on the user's machine might disable taskbar pinning. So, before you attempt to pin your app, you need to check whether pinning to the taskbar is supported. The TaskbarManager.IsPinningAllowed property returns `true` if the taskbar is present and allows pinning.

C#

```
// Check if taskbar allows pinning, apps may request pinning, but pinning
may not be allowed at any given time. It is suggested that apps check
whether pinning is allowed before a UX is surfaced in order to prevent
confusing users.

bool isPinningAllowed = TaskbarManager.GetDefault().IsPinningAllowed;
```

ⓘ Important

There are also requirements that must be met at the time the call is actually made for the pin request to be allowed:

- App is in foreground
- App has a Start menu entry

These requirements won't result in an exception if not met, the pin request will just be denied. `IsPinningAllowed` can be called to determine if a pin request (prompt) will be allowed.

ⓘ Note

If you don't want to pin your app to the taskbar and just want to find out whether the taskbar is available, use the TaskbarManager.IsSupported property.

3. Check whether your app is currently pinned to the taskbar

Obviously, there's no point in asking the user to let you pin the app to the taskbar if it's already pinned there. You can use the TaskbarManager.IsCurrentAppPinnedAsync method to check whether the app is already pinned before asking the user.

C#

```
// Check whether your app is currently pinned
bool isPinned = await TaskbarManager.GetDefault().IsCurrentAppPinnedAsync();

if (isPinned)
{
    // The app is already pinned--no point in asking to pin it again!
}
else
{
    //The app is not pinned.
}
```

4. Pin your app

If the taskbar is present and pinning is allowed and your app currently isn't pinned, you might want to show a subtle tip to let users know that they can pin your app. For example, you might show a pin icon somewhere in your UI that the user can click.

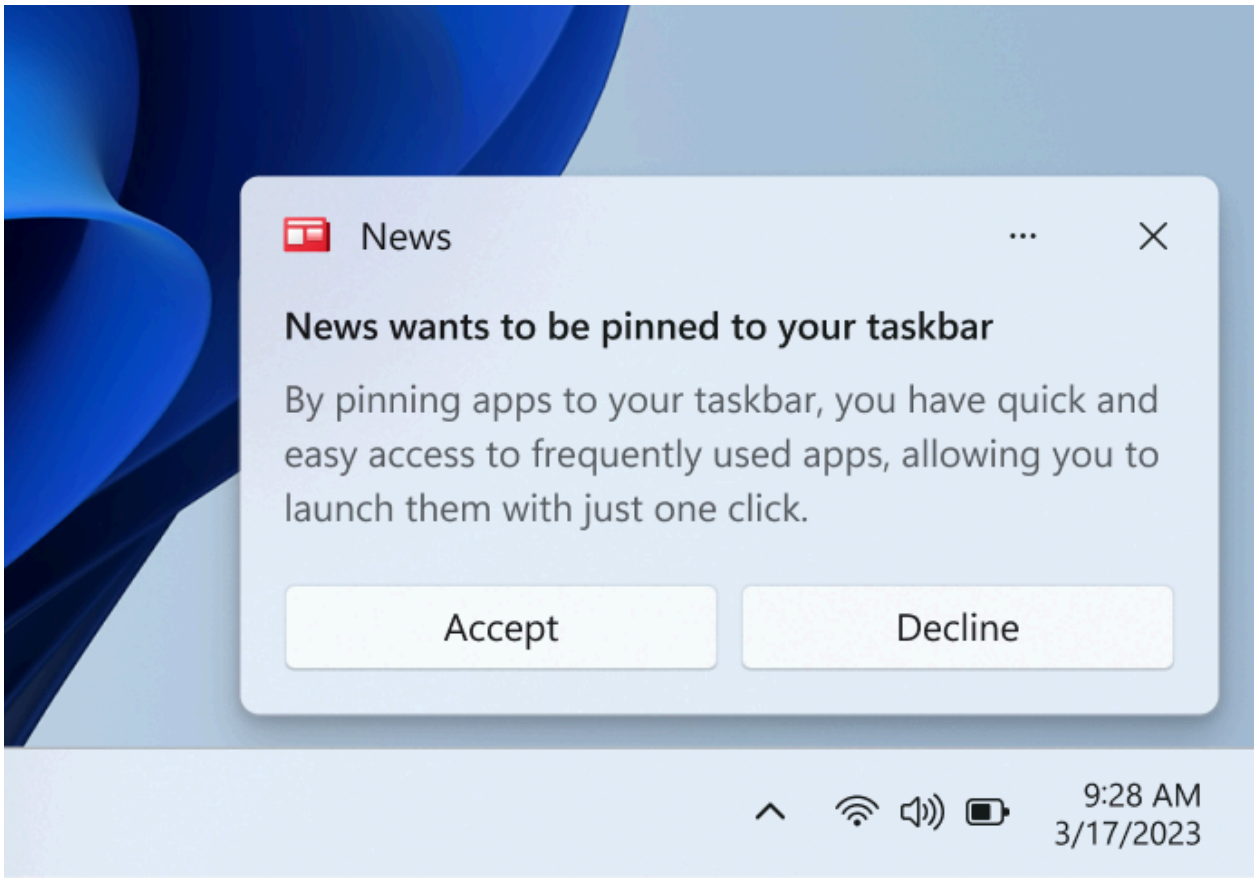
If the user clicks your pin suggestion UI, you would then call the TaskbarManager.RequestPinCurrentAppAsync method. This method displays a dialog that asks the user to confirm that they want your app pinned to the taskbar.

ⓘ Important

This must be called from a foreground UI thread, otherwise an exception will be thrown.

C#

```
// Request to be pinned to the taskbar.
bool isPinned = await
TaskbarManager.GetDefault().RequestPinCurrentAppAsync();
```



This method returns a boolean value that indicates whether your app is now pinned to the taskbar. If your app was already pinned, the method immediately returns `true` without showing the dialog to the user. If the user clicks "no" on the dialog, or pinning your app to the taskbar isn't allowed, the method returns `false`. Otherwise, the user clicked yes and the app was pinned, and the API will return `true`.

Notifications Visualizer

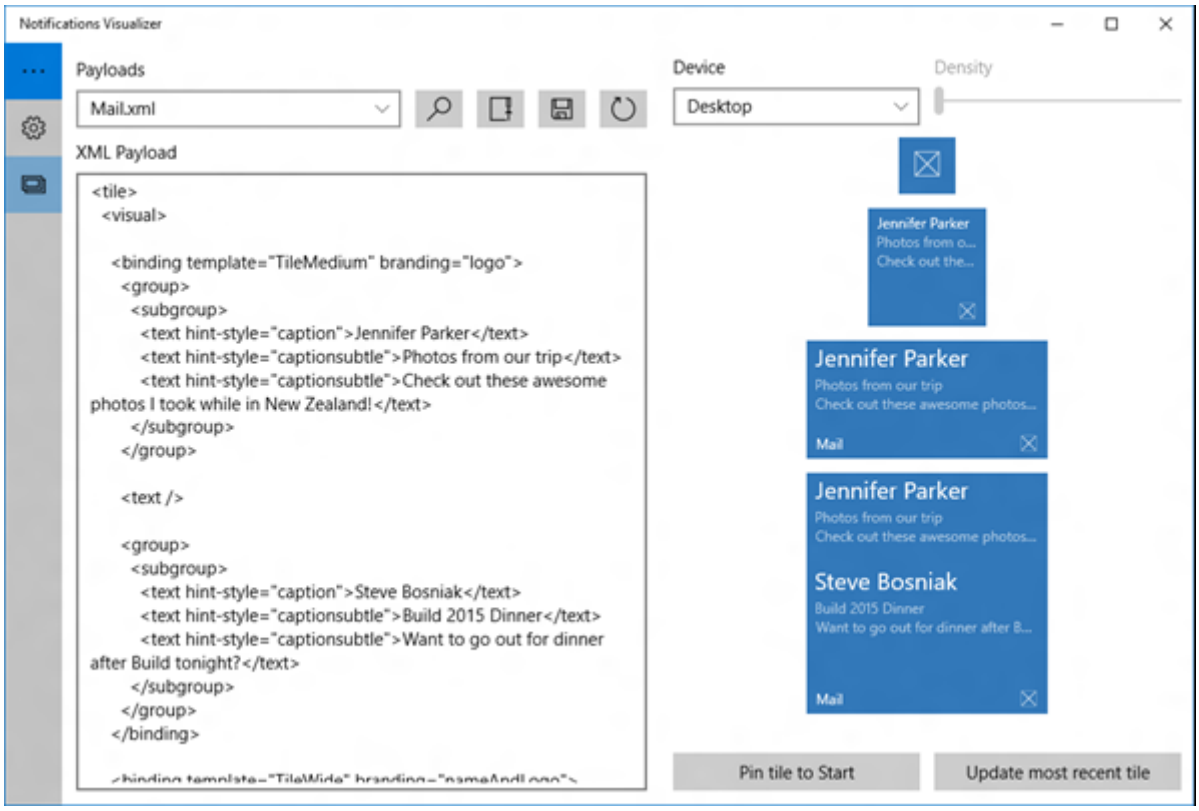
Article • 06/24/2021

Notifications Visualizer is a new Windows app in the Store that helps developers design adaptive Live Tiles and interactive toast notifications for Windows 10.

Overview

Notifications Visualizer provides instant visual previews of your tile and toast notification as you edit the XML payload, similar to Visual Studio's XAML editor/design view. The app also checks for errors, which ensures that you create a valid tile or toast notification payload.

This screenshot from the app shows the XML payload and how tile sizes appear on a selected device:



With Notifications Visualizer, you can create and test adaptive tile and toast payloads without having to edit and deploy your own app. Once you've created a payload with ideal visual results, you can integrate that into your app. See Send a local tile notification and Send a local toast to learn more.

Note Notifications Visualizer's simulation of the Windows Start menu and toast notifications isn't always completely accurate, and it doesn't support some advanced payload properties. When you have the tile or toast you want, test it by pinning the tile or popping the toast to verify that it appears as you intend.

Features

Notifications Visualizer comes with a number of sample payloads to showcase what's possible with adaptive Live Tiles and interactive toasts to help you get started. You can experiment with all the different text options, groups/subgroups, background images, and you can see how the tile adapts to different devices and screens. Once you've made changes, you can save your updated payload to a file for future use.

The editor provides real-time errors and warnings. For example, if your payload is greater than 5 KB (a platform limitation), Notifications Visualizer warns you that your payload exceeds that limit. It gives you warnings for incorrect attribute names or values, which helps you debug visual issues.

You can control tile properties like display name, color, logos, ShowName, and badge value. These options help you instantly understand how your tile properties and tile notification payloads interact, and the results they produce.

This screenshot from the app shows the tile editor:

Choose a notification delivery method

Article • 06/24/2021

This article covers the four notification options—local, scheduled, periodic, and push—that deliver tile and badge updates and toast notification content. A tile or a toast notification can get information to your user even when the user is not directly engaged with your app. The nature and content of your app and the information that you want to deliver can help you determine which notification method or methods is best for your scenario.

Notification delivery methods overview

There are four mechanisms that an app can use to deliver a notification:

- **Local**
- **Scheduled**
- **Periodic**
- **Push**

This table summarizes the notification delivery types.

Expand table

Delivery method	Use with	Description	Examples
Local	Tile, Badge, Toast	A set of API calls that send notifications while your app is running, directly updating the tile or badge, or sending a toast notification.	• A music app updates its tile to show what's "Now Playing". • A game app updates its tile with the user's high score when the user leaves the game. • A badge whose glyph indicates that there's new info int the app is cleared when the app is activated.

Delivery method	Use with	Description	Examples
Scheduled	Tile, Toast	A set of API calls that schedule a notification in advance, to update at the time you specify.	• A calendar app sets a toast notification reminder for an upcoming meeting.
Periodic	Tile, Badge	Notifications that update tiles and badges regularly at a fixed time interval by polling a cloud service for new content.	• A weather app updates its tile, which shows the forecast, at 30-minute intervals. • A "daily deals" site updates its deal-of-the-day every morning. • A tile that displays the days until an event updates the displayed countdown each day at midnight.
Push	Tile, Badge, Toast, Raw	Notifications sent from a cloud server, even if your app isn't running.	• A shopping app sends a toast notification to let a user know about a sale on an item that they're watching. • A news app updates its tile with breaking news as it happens. • A sports app keeps its tile up-to-date during an ongoing game. • A communication

Delivery method	Use with	Description	Examples
			app provides alerts about incoming messages or phone calls.

Local notifications

Updating the app tile or badge or raising a toast notification while the app is running is the simplest of the notification delivery mechanisms; it only requires local API calls. Every app can have useful or interesting information to show on the tile, even if that content only changes after the user launches and interacts with the app. Local notifications are also a good way to keep the app tile current, even if you also use one of the other notification mechanisms. For instance, a photo app tile could show photos from a recently added album.

We recommended that your app update its tile locally on first launch, or at least immediately after the user makes a change that your app would normally reflect on the tile. That update isn't seen until the user leaves the app, but by making that change while the app is being used ensures that the tile is already up-to-date when the user departs.

While the API calls are local, the notifications can reference web images. If the web image is not available for download, is corrupted, or doesn't meet the image specifications, tiles and toast respond differently:

- Tiles: The update is not shown
- Toast: The notification is displayed, but your image is dropped

By default, local toast notifications expire in three days, and local tile notifications never expire. We recommend overriding these defaults with an explicit expiration time that makes sense for your notifications (toasts have a max of three days).

For more information, see these topics:

- Send a local tile notification
- Send a local toast notification
- Windows app notifications code samples

Scheduled notifications

Scheduled notifications are the subset of local notifications that can specify the precise time when a tile should be updated or a toast notification should be shown. Scheduled notifications are ideal in situations where the content to be updated is known in advance, such as a meeting invitation. If you don't have advance knowledge of the notification content, you should use a push or periodic notification.

Note that scheduled notifications cannot be used for badge notifications; badge notifications are best served by local, periodic, or push notifications.

By default, scheduled notifications expire three days from the time they are delivered. You can override this default expiration time on scheduled tile notifications, but you cannot override the expiration time on scheduled toasts.

For more information, see these topics:

- Scheduling a toast notification
- Windows app notifications code samples

Periodic notifications

Periodic notifications give you live tile updates with a minimal cloud service and client investment. They are also an excellent method of distributing the same content to a wide audience. Your client code specifies the URL of a cloud location that Windows polls for tile or badge updates, and how often the location should be polled. At each polling interval, Windows contacts the URL to download the specified XML content and display it on the tile.

Periodic notifications require the app to host a cloud service, and this service will be polled at the specified interval by all users who have the app installed. Note that periodic updates cannot be used for toast notifications; toast notifications are best served by scheduled or push notifications.

By default, periodic notifications expire three days from the time polling occurs. If needed, you can override this default with an explicit expiration time.

For more information, see these topics:

- Periodic notification overview
- Windows app notifications code samples

Push notifications

Push notifications are ideal to communicate real-time data or data that is personalized for your user. Push notifications are used for content that is generated at unpredictable times, such as breaking news, social network updates, or instant messages. Push notifications are also useful in situations where the data is time-sensitive in a way that would not suit periodic notifications, such as sports scores during a game.

Push notifications require a cloud service that manages push notification channels and chooses when and to whom to send notifications.

By default, push notifications expire three days from the time they are received by the device. If needed, you can override this default with an explicit expiration time (toasts have a max of three days).

Choosing the right push notification channel type

Article • 08/03/2022

This article covers the three types of Windows push notification channels (primary, secondary, and alternate) that help you deliver content to your app.

(For details on how to create push notifications, see the Windows Push Notification Services (WNS) overview.)

Types of push channels

There are three types of push channels that can be used to send notifications to a Windows app. They are:

Primary channel - the "traditional" push channel. Can be used by any app in the store to send toast, tile, raw, or badge notifications. Learn more here.

Secondary tile channel - used to push tile updates to a secondary tile. Can only be used to send tile or badge notifications to a secondary tile pinned on the user's start screen

Alternate channel - **No longer supported** - A new type of channel added in the Creators Update. It allows for raw notifications to be sent to any Windows app, including those which aren't registered in the Store. Again, note that the alternate channel is no longer supported.

> ⓘ **Note**
>
> No matter which push channel you use, once your app is running on the device, it will always be able to send local toast, tile, or badge notifications. It can send local notifications from the foreground app processes or from a background task.

Primary channels

These are the most commonly used channels on Windows right now, and are good for almost any scenario where your app is going to be distributed through the Microsoft Store. They allow you to send all types of notifications to the app.

What do primary channels enable?

- **Sending tile or badge updates to the primary tile.** If the user has chosen to pin your tile to the start screen, this is your chance to show off. Send updates with useful information or reminders of experiences within your app.
- **Sending toast notifications.** Toast notifications are a chance to get some information in front of the user immediately. They are painted by the shell over top of most apps, and live in the action

center so the user can go back and interact with them later.
- **Sending raw notifications to trigger a background task.** Sometimes you want to do some work on behalf of the user based on a notification. Raw notifications allow your app's background tasks to run
- **Message encryption in transit provided by Windows using TLS.** Messages are encrypted on the wire both coming into WNS and going to the user's device.

Limitations of primary channels

- Requires using the WNS REST API to push notifications, which isn't standard across device vendors.
- Only one channel can be created per app
- Requires your app to be registered in the Microsoft Store

Creating a primary channel

```
C#

PushNotificationChannel channel =
    await
PushNotificationChannelManager.CreatePushNotificationChannelForApplicationAsync();
```

Secondary tile channels

These are channels that can be used to push tile and badge updates to a secondary tile. These are used by apps to notify users of interesting actions or information that they can interact with in the app, such as new messages in a group chat or an updated sports score.

What do secondary tile channels enable?

- Sending tile or badge notifications to secondary tiles. Secondary tiles are a great way to pull users back into your app. They are a deep link to information they care about, and putting relevant information on the tiles helps to bring them back again and again.
- Separation of channels (and expiries) between various tiles. This allows you to separate the logic in the backend between the various types of secondary tiles that a user might pin to their start screen.
- Message encryption in transit provided by Windows using TLS. Messages are encrypted on the wire both coming into WNS and going to the user's device.

Limitations of secondary tile channels

- No toast or raw notifications allowed. Toast or raw notifications sent to a secondary tile are ignored by the system.
- Requires your app to be registered in the Microsoft Store

Creating a secondary tile channel

```
C#

PushNotificationChannel channel =
    await
PushNotificationChannelManager.CreatePushNotificationChannelForSecondaryTileAsync(tileId
);
```

Alternate channels

Alternate channels enable apps to send push notifications without registering to the Microsoft Store or creating push channels outside of the primary one used for the app.

> ⓘ **Note**
>
> As of July 1, 2021 applications that want to use the web push channel or the alternate channel to send browser based notifications through WNS will need to be onboarded to the Microsoft Store.

What do alternate channels enable?

- Send raw push notifications to a Windows running on any Windows device. Alternate channels only allow for raw notifications (however you can still wake up a background task to locally show toast or tile notifications).
- Allows apps to create multiple raw push channels for different features within the app. An app can create up to 1000 alternate channels, and each one is valid for 30 days. Each of these channels can be managed or revoked separately by the app.
- Alternate push channels can be created without registering an app with the Microsoft Store. If you app is going to be installed on devices without registering it in the Microsoft Store, it will still be able to receive push notifications.
- Servers can push notifications using the W3C standard REST APIs and VAPID protocol. Alternate channels use the W3C standard protocol, this allows you to simplify the server logic that needs to be maintained.
- Full, end-to-end, message encryption. While the primary channel provides encryption while in transit, if you want to be extra secure, alternate channels enable your app to pass through encryption headers to protect a message.

Limitations of alternate channels

- Your app's server cannot send push toast, tile, or badge type notifications. You can only send push raw notifications. Your app is still able to send local notifications from your background task.
- Requires a different REST API than either primary or secondary tile channels. Using the standard W3C REST API means that your app will need to have different logic for sending push toast or

tile updates

Creating an alternate channel

```
C#

PushNotificationChannel webChannel =
    await
PushNotificationChannelManager.GetDefault().CreateRawPushNotificationChannelWithAlternat
eKeyForApplicationAsync(applicationServerKey, appChannelId);
```

Channel type comparison

Here is a quick comparison between the different types of channels:

Expand table

Type	Push toast?	Push tile/badge?	Push raw notifications?	Authentication	API	Store registration required?	Channels	Encryption
Primary	Yes	Yes - primary tile only	Yes	OAuth	WNS REST API	Yes	One per app	In Transit
Secondary Tile	No	Yes - secondary tile only	No	OAuth	WNS REST API	Yes	One per secondary tile	In Transit
Alternate	No	No	Yes	VAPID	WebPush W3C Standard	No	1,000 per app	In transit + end to end encryption possible with header pass through (requires app code)

Choosing the right channel

In general, we recommend using the primary channel in your app, with a few exceptions:

1. If you are pushing a tile update to a secondary tile, use the secondary tile push channel.
2. If you are passing out channels to other services (such as in the case of a browser) use the alternate channel.
3. If you are creating an app that won't be listed in the Windows store (such as an LOB app) use an alternate channel.

4. If you have existing web push code on your server you wish to reuse or have a need for multiple channels in your backend service, use alternate channels.

Periodic notification overview

Article • 06/24/2021

Periodic notifications, which are also called polled notifications, update tiles and badges at a fixed interval by downloading content from a cloud service. To use periodic notifications, your client app code needs to provide two pieces of information:

- The Uniform Resource Identifier (URI) of a web location for Windows to poll for tile or badge updates for your app
- How often that URI should be polled

Periodic notifications enable your app to get live tile updates with minimal cloud service and client investment. Periodic notifications are a good delivery method for distributing the same content to a wide audience.

Note You can learn more by downloading the Push and periodic notifications sample for Windows 8.1 and re-using its source code in your Windows 10 app.

How it works

Periodic notifications require that your app hosts a cloud service. The service will be polled periodically by all users who have the app installed. At each polling interval, such as once an hour, Windows sends an HTTP GET request to the URI, downloads the requested tile or badge content (as XML) that is supplied in response to the request, and displays the content on the app's tile.

Note that periodic updates cannot be used with toast notifications. Toast is best delivered through scheduled or push notifications.

URI location and XML content

Any valid HTTP or HTTPS web address can be used as the URI to be polled.

The cloud server's response includes the downloaded content. The content returned from the URI must conform to the Tile or Badge XML schema specification, and must be UTF-8 encoded. You can use defined HTTP headers to specify the expiration time or tag for the notification.

Polling Behavior

Call one of these methods to begin polling:

- **StartPeriodicUpdate** (Tile)
- **StartPeriodicUpdate** (Badge)
- **StartPeriodicUpdateBatch** (Tile)

When you call one of these methods, the URI is immediately polled and the tile or badge is updated with the received contents. After this initial poll, Windows continues to provide updates at the requested interval. Polling continues until you explicitly stop it (with **TileUpdater.StopPeriodicUpdate**), your app is uninstalled, or, in the case of a secondary tile, the tile is removed. Otherwise, Windows continues to poll for updates to your tile or badge even if your app is never launched again.

The recurrence interval

You specify the recurrence interval as a parameter of the methods listed above. Note that while Windows makes a best effort to poll as requested, the interval is not precise. The requested poll interval can be delayed by up to 15 minutes at the discretion of Windows.

The start time

You optionally can specify a particular time of day to begin polling. Consider an app that changes its tile content just once a day. In such a case, we recommend that you poll close to the time that you update your cloud service. For example, if a daily shopping site publishes the day's offers at 8 AM, poll for new tile content shortly after 8 AM.

If you provide a start time, the first call to the method polls for content immediately. Then, regular polling starts within 15 minutes of the provided start time.

Automatic retry behavior

The URI is polled only if the device is online. If the network is available but the URI cannot be contacted for any reason, this iteration of the polling interval is skipped, and the URI will be polled again at the next interval. If the device is in an off, sleep, or hibernated state when a polling interval is reached, the URI is polled when the device returns from its off or sleep state.

Handling app updates

If you release an app update that changes your polling URI, you should add a daily time trigger background task which calls StartPeriodicUpdate with the new URI to ensure your tiles are using the new URI. Otherwise, if users receive your app update but don't launch your app, their tiles will still be using the old URI, which may fail to display if the URI is now invalid or if the returned payload references local images that no longer exist.

Expiration of tile and badge notifications

By default, periodic tile and badge notifications expire three days from the time they are downloaded. When a notification expires, the content is removed from the badge, tile, or queue and is no longer shown to the user. It is a best practice to set an explicit expiration time on all periodic tile and badge notifications, using a time that makes sense for your app or notification, to ensure that the content does not persist longer than it is relevant. An explicit expiration time is essential for content with a defined life span. It also assures the removal of stale content if your cloud service becomes unreachable, or if the user disconnects from the network for an extended period of time.

Your cloud service sets an expiration date and time for a notification by including the X-WNS-Expires HTTP header in the response payload. The X-WNS-Expires HTTP header conforms to the HTTP-date format. For more information, see **StartPeriodicUpdate** or **StartPeriodicUpdateBatch**.

For example, during a stock market's active trading day, you can set the expiration for a stock price update to twice that of your polling interval (such as one hour after receipt if you are polling every half-hour). As another example, a news app might determine that one day is an appropriate expiration time for a daily news tile update.

Periodic notifications in the notification queue

You can use periodic tile updates with notification cycling. By default, a tile on the Start screen shows the content of a single notification until it is replaced by a new notification. When you enable cycling, up to five notifications are maintained in a queue and the tile cycles through them.

If the queue has reached its capacity of five notifications, the next new notification replaces the oldest notification in the queue. However, by setting tags on your notifications, you can affect the queue's replacement policy. A tag is an app-specific, case-insensitive string of up to 16 alphanumeric characters, specified in the X-WNS-Tag HTTP header in the response payload. Windows compares the tag of an incoming notification with the tags of all notifications already in the queue. If a match is found, the new notification replaces the queued notification with the same tag. If no match is

found, the default replacement rule is applied and the new notification replaces the oldest notification in the queue.

You can use notification queuing and tagging to implement a variety of rich notification scenarios. For example, a stock app could send five notifications, each about a different stock and each tagged with a stock name. This prevents the queue from ever containing two notifications for the same stock, the older of which is out of date.

For more information, see Using the notification queue.

Enabling the notification queue

To implement a notification queue, first enable the queue for your tile (see How to use the notification queue with local notifications). The call to enable the queue needs to be done only once in your app's lifetime, but there is no harm in calling it each time your app is launched.

Polling for more than one notification at a time

You must provide a unique URI for each notification that you'd like Windows to download for your tile. By using the **StartPeriodicUpdateBatch** method, you can provide up to five URIs at once for use with the notification queue. Each URI is polled for a single notification payload, at or near the same time. Each polled URI can return its own expiration and tag value.

Input and interactions

Article • 10/04/2021

UWP apps automatically handle a wide variety of inputs and run on a variety of devices —there's nothing extra you need to do to enable touch input, for example. But there are times when you might want to optimize your app for certain types of input or devices. For example, if you're creating a painting app, you might want to customize the way you handle pen input.

The design and coding instructions in this section help you customize your UWP app for specific types of inputs.

Input primer

Familiarize yourself with each input device type and its behaviors, capabilities, and limitations when paired with certain form factors.

Gaze input

Track a user's gaze based on the location and movement of their eyes and head.

Input

Identify input devices
Pointer
Pen and Windows Ink
Touch
Mouse
Keyboard

Speech and AI

Speech
Cortana

Interaction primer

Article • 10/24/2022

User interactions in the Windows app are a combination of input and output sources (such as mouse, keyboard, pen, touch, touchpad, speech, **Cortana**, controller, gesture, gaze, and so on), along with various modes or modifiers that enable extended experiences (including mouse wheel and buttons, pen eraser and barrel buttons, touch keyboard, and background app services).

UWP uses a "smart" contextual interaction system that, in most cases, eliminates the need to individually handle the unique types of input received by your app. This includes handling touch, touchpad, mouse, and pen input as a generic pointer type to support static gestures such as tap or press-and-hold, manipulation gestures such as slide for panning, or rendering digital ink.

Familiarize yourself with each input device type and its behaviors, capabilities, and limitations when paired with certain form factors. This can help you decide whether the platform controls and affordances are sufficient for your app, or require you to provide customized interaction experiences.

Gaze

For **Windows 10 April 2018 Update**, we introduced support for Gaze input using eye and head tracking input devices.

> **Note**
>
> Support for eye tracking hardware was introduced in **Windows 10 Fall Creators Update** along with **Eye control**, a built-in feature that lets you use your eyes to control the on-screen pointer, type with the on-screen keyboard, and communicate with people using text-to-speech.

Device support

- Tablet
- PCs and laptops

Typical usage

Track a user's gaze, attention, and presence based on the location and movement of their eyes. This powerful new way to use and interact with Windows apps is especially useful as an assistive technology for users with neuro-muscular diseases (such as ALS) and other disabilities involving impaired muscle or nerve functions. Gaze input also provides compelling opportunities for both gaming (including target acquisition and tracking) and traditional productivity applications, kiosks, and other interactive scenarios where traditional input devices (keyboard, mouse, touch) are not available, or where it might be useful/helpful to free up the user's hands for other tasks (such as holding shopping bags).

More info

Gaze interactions and eye tracking

Surface Dial

For **Windows 10 Anniversary Update**, we introduced the Windows Wheel category of input device. The Surface Dial is the first in this class of device.

Device support

- Tablet
- PCs and laptops

Typical usage

With a form factor based on a rotate action (or gesture), the Surface Dial is intended as a secondary, multi-modal input device that complements or modifies input from a primary device. In most cases, the device is manipulated by a user's non-dominant hand while they perform a task with their dominant hand (such as inking with a pen).

More info

Surface Dial design guidelines

Cortana

In Windows 10, **Cortana** extensibility lets you handle voice commands from a user and launch your application to carry out a single action.

Device support

- Phones and phablets
- Tablet
- PCs and laptops
- Surface Hub
- IoT
- Xbox
- HoloLens

Typical usage

A voice command is a single utterance, defined in a Voice Command Definition (VCD) file, directed at an installed app through **Cortana**. The app can be launched in the foreground or background, depending on the level and complexity of the interaction. For instance, voice commands that require additional context or user input are best handled in the foreground, while basic commands can be handled in the background.

Integrating the basic functionality of your app, and providing a central entry point for the user to accomplish most of the tasks without opening your app directly, lets **Cortana** become a liaison between your app and the user. In many cases, this can save the user significant time and effort. For more info, see Cortana design guidelines.

More info

Cortana design guidelines

Speech

Speech is an effective and natural way for people to interact with applications. It's an easy and accurate way to communicate with applications, and lets people be productive and stay informed in a variety of situations.

Speech can complement or, in many cases, be the primary input type, depending on the user's device. For example, devices such as HoloLens and Xbox do not support traditional input types (aside from a software keyboard in specific scenarios). Instead, they rely on speech input and output (often combined with other non-traditional input types such as gaze and gesture) for most user interactions.

Text-to-speech (also known as TTS, or speech synthesis) is used to inform or direct the user.

Device support

- Phones and phablets
- Tablet
- PCs and laptops
- Surface Hub
- IoT
- Xbox
- HoloLens

Typical usage

There are three modes of Speech interaction:

Natural language

Natural language is how we verbally interact with people on a regular basis. Our speech varies from person to person and situation to situation, and is generally understood. When it's not, we often use different words and word order to get the same idea across.

Natural language interactions with an app are similar: we speak to the app through our device as if it were a person and expect it to understand and react accordingly.

Natural language is the most advanced mode of speech interaction, and can be implemented and exposed through **Cortana**.

Command and control

Command and control is the use of verbal commands to activate controls and functionality such as clicking a button or selecting a menu item.

As command and control is critical to a successful user experience, a single input type is generally not recommended. Speech is typically one of several input options for a user based on their preferences or hardware capabilities.

Dictation

The most basic speech input method. Each utterance is converted to text.

Dictation is typically used when an app doesn't need to understand meaning or intent.

More info

Speech design guidelines

Pen

A pen (or stylus) can serve as a pixel precise pointing device, like a mouse, and is the optimal device for digital ink input.

Note There are two types of pen devices: active and passive.

- Passive pens do not contain electronics, and effectively emulate touch input from a finger. They require a basic device display that recognizes input based on contact pressure. Because users often rest their hand as they write on the input surface, input data can become polluted due to unsuccessful palm rejection.
- Active pens contain electronics and can work with complex device displays to provide much more extensive input data (including hover, or proximity data) to the system and your app. Palm rejection is much more robust.

When we refer to pen devices here, we are referring to active pens that provide rich input data and are used primarily for precise ink and pointing interactions.

Device support

- Phones and phablets
- Tablet
- PCs and laptops
- Surface Hub
- IoT

Typical usage

The Windows ink platform, together with a pen, provides a natural way to create handwritten notes, drawings, and annotations. The platform supports capturing ink data from digitizer input, generating ink data, rendering that data as ink strokes on the output device, managing the ink data, and performing handwriting recognition. In addition to capturing the spatial movements of the pen as the user writes or draws, your app can also collect info such as pressure, shape, color, and opacity, to offer user experiences that closely resemble drawing on paper with a pen, pencil, or brush.

Where pen and touch input diverge is the ability for touch to emulate direct manipulation of UI elements on the screen through physical gestures performed on those objects (such as swiping, sliding, dragging, rotating, and so on).

You should provide pen-specific UI commands, or affordances, to support these interactions. For example, use previous and next (or + and -) buttons to let users flip through pages of content, or rotate, resize, and zoom objects.

More info

Pen design guidelines

Touch

With touch, physical gestures from one or more fingers can be used to either emulate the direct manipulation of UI elements (such as panning, rotating, resizing, or moving), as an alternative input method (similar to mouse or pen), or as a complementary input method (to modify aspects of other input, such as smudging an ink stroke drawn with a pen). Tactile experiences such as this can provide more natural, real-world sensations for users as they interact with elements on a screen.

Device support

- Phones and phablets
- Tablet
- PCs and laptops
- Surface Hub
- IoT

Typical usage

Support for touch input can vary significantly, depending on the device.

Some devices don't support touch at all, some devices support a single touch contact, while others support multi-touch (two or more contacts).

Most devices that support multi-touch input, typically recognize ten unique, concurrent contacts.

Surface Hub devices recognize 100 unique, concurrent touch contacts.

In general, touch is:

- Single user, unless being used with a Microsoft Team device like Surface Hub, where collaboration is emphasized.
- Not constrained to device orientation.
- Used for all interactions, including text input (touch keyboard) and inking (app-configured).

More info

Touch design guidelines

Touchpad

A touchpad combines both indirect multi-touch input with the precision input of a pointing device, such as a mouse. This combination makes the touchpad suited to both a touch-optimized UI and the smaller targets of productivity apps.

Device support

- PCs and laptops
- IoT

Typical usage

Touchpads typically support a set of touch gestures that provide support similar to touch for direct manipulation of objects and UI.

Because of this convergence of interaction experiences supported by touchpads, we recommend also providing mouse-style UI commands or affordances rather than relying solely on support for touch input. Provide touchpad-specific UI commands, or affordances, to support these interactions.

You should provide mouse-specific UI commands, or affordances, to support these interactions. For example, use previous and next (or + and -) buttons to let users flip through pages of content, or rotate, resize, and zoom objects.

More info

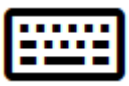
Touchpad design guidelines

Keyboard

A keyboard is the primary input device for text, and is often indispensable to people with certain disabilities or users who consider it a faster and more efficient way to interact with an app.

Device support

- Phones and phablets
- Tablet
- PCs and laptops
- Surface Hub
- IoT
- Xbox
- HoloLens



Typical usage

Users can interact with Universal Windows apps through a hardware keyboard and two software keyboards: the On-Screen Keyboard (OSK) and the touch keyboard.

The OSK is a visual, software keyboard that you can use instead of the physical keyboard to type and enter data using touch, mouse, pen/stylus or other pointing device (a touch screen is not required). The OSK is provided for systems that don't have a physical keyboard, or for users whose mobility impairments prevent them from using traditional

physical input devices. The OSK emulates most, if not all, the functionality of a hardware keyboard.

The touch keyboard is a visual, software keyboard used for text entry with touch input. The touch keyboard is not a replacement for the OSK as it is used for text input only (it doesn't emulate the hardware keyboard) and appears only when a text field or other editable text control gets focus. The touch keyboard does not support app or system commands.

Note The OSK has priority over the touch keyboard, which won't be shown if the OSK is present.

In general, a keyboard is:

- Single user.
- Not constrained to device orientation.
- Used for text input, navigation, gameplay, and accessibility.
- Always available, either proactively or reactively.

More info

Keyboard design guidelines

Mouse

A mouse is best suited for productivity apps and high-density UI where user interactions require pixel-level precision for targeting and commanding.

Device support

- Phones and phablets
- Tablet
- PCs and laptops
- Surface Hub
- IoT

Typical usage

Mouse input can be modified with the addition of various keyboard keys (Ctrl, Shift, Alt, and so on). These keys can be combined with the left mouse button, the right mouse button, the wheel button, and the X buttons for an expanded mouse-optimized command set. (Some Microsoft mouse devices have two additional buttons, referred to as X buttons, typically used to navigate back and forward in Web browsers).

Similar to pen, where mouse and touch input diverge is the ability for touch to emulate direct manipulation of UI elements on the screen through physical gestures performed on those objects (such as swiping, sliding, dragging, rotating, and so on).

You should provide mouse-specific UI commands, or affordances, to support these interactions. For example, use previous and next (or + and -) buttons to let users flip through pages of content, or rotate, resize, and zoom objects.

More info

Mouse design guidelines

Gesture

A gesture is any form of user movement that is recognized as input for controlling or interacting with an application. Gestures take many forms, from simply using a hand to target something on the screen, to specific, learned patterns of movement, to long stretches of continuous movement using the entire body. Be careful when designing custom gestures, as their meaning can vary depending on locale and culture.

Device support

- PCs and laptops
- IoT
- Xbox
- HoloLens

Typical usage

Static gesture events are fired after an interaction is complete.

- Static gesture events include Tapped, DoubleTapped, RightTapped, and Holding.

Manipulation gesture events indicate an ongoing interaction. They start firing when the user touches an element and continue until the user lifts their finger(s), or the manipulation is canceled.

- Manipulation events include multi-touch interactions such as zooming, panning, or rotating, and interactions that use inertia and velocity data such as dragging. (The information provided by the manipulation events doesn't identify the interaction, but rather provides data such as position, translation delta, and velocity.)

- Pointer events such as PointerPressed and PointerMoved provide low-level details for each touch contact, including pointer motion and the ability to distinguish press and release events.

Because of the convergence of interaction experiences supported by Windows, we recommend also providing mouse-style UI commands or affordances rather than relying solely on support for touch input. For example, use previous and next (or + and -) buttons to let users flip through pages of content, or rotate, resize, and zoom objects.

Gamepad/Controller

The gamepad/controller is a highly specialized device typically dedicated to playing games. However, it is also used for to emulate basic keyboard input and provides a UI navigation experience very similar to the keyboard.

Device support

- PCs and laptops
- IoT
- Xbox

Typical usage

Playing games and interacting with a specialized console.

Multiple inputs

Accommodating as many users and devices as possible and designing your apps to work with as many input types (gesture, speech, touch, touchpad, mouse, and keyboard) as possible maximizes flexibility, usability, and accessibility.

Device support

- Phones and phablets
- Tablet
- PCs and laptops
- Surface Hub
- IoT
- Xbox
- HoloLens

Typical usage

Just as people use a combination of voice and gesture when communicating with each other, multiple types and modes of input can also be useful when interacting with an app. However, these combined interactions need to be as intuitive and natural as possible as they can also create a very confusing experience.

Handle pointer input

Article • 06/24/2021

Receive, process, and manage input data from pointing devices (such as touch, mouse, pen/stylus, and touchpad) in your Windows applications.

> **Important**
>
> Create custom interactions only if there is a clear, well-defined requirement and the interactions supported by the platform controls don't support your scenario.
> If you customize the interaction experiences in your Windows application, users expect them to be consistent, intuitive, and discoverable. For these reasons, we recommend that you model your custom interactions on those supported by the **platform controls**. The platform controls provide the full Windows app user interaction experience, including standard interactions, animated physics effects, visual feedback, and accessibility.

Important APIs

- Windows.Devices.Input
- Windows.UI.Input
- Windows.UI.Xaml.Input

Pointers

Most interaction experiences typically involve the user identifying the object they want to interact with by pointing at it through input devices such as touch, mouse, pen/stylus, and touchpad. Because the raw Human Interface Device (HID) data provided by these input devices includes many common properties, the data is promoted and consolidated into a unified input stack and exposed as device-agnostic pointer data. Your Windows applications can then consume this data without worrying about the input device being used.

> **Note**
>
> Device-specific info is also promoted from the raw HID data should your app require it.

Each input point (or contact) on the input stack is represented by a **Pointer** object exposed through the **PointerRoutedEventArgs** parameter in the various pointer event handlers. In the case of multi-pen or multi-touch input, each contact is treated as a unique input pointer.

Pointer events

Pointer events expose basic info such as input device type and detection state (in range or in contact), and extended info such as location, pressure, and contact geometry. In addition, specific device properties such as which mouse button a user pressed or whether the pen eraser tip is being used are also available. If your app needs to differentiate between input devices and their capabilities, see Identify input devices.

Windows apps can listen for the following pointer events:

> **Note**
>
> Constrain pointer input to a specific UI element by calling **CapturePointer** on that element within a pointer event handler. When a pointer is captured by an element, only that object receives pointer input events, even when the pointer moves outside the bounding area of the object. The **IsInContact** (mouse button pressed, touch or stylus in contact) must be true for **CapturePointer** to be successful.

Event	Description
PointerCanceled	Occurs when a pointer is canceled by the platform. This can occur in the following circumstances: • Touch pointers are canceled when a pen is detected within range of the input surface. • An active contact is not detected for more than 100 ms. • Monitor/display is changed (resolution, settings, multi-mon configuration). • The desktop is locked or the user has logged off. • The number of simultaneous contacts exceeded the number supported by the device.

Event	Description
PointerCaptureLost	Occurs when another UI element captures the pointer, the pointer was released, or another pointer was programmatically captured. **Note** There is no corresponding pointer capture event.
PointerEntered	Occurs when a pointer enters the bounding area of an element. This can happen in slightly different ways for touch, touchpad, mouse, and pen input. • Touch requires a finger contact to fire this event, either from a direct touch down on the element or from moving into the bounding area of the element. • Mouse and touchpad both have an on-screen cursor that is always visible and fires this event even if no mouse or touchpad button is pressed. • Like touch, pen fires this event with a direct pen down on the element or from moving into the bounding area of the element. However, pen also has a hover state (IsInRange) that, when true, fires this event.

Event	Description
PointerExited	Occurs when a pointer leaves the bounding area of an element. This can happen in slightly different ways for touch, touchpad, mouse, and pen input. • Touch requires a finger contact and fires this event when the pointer moves out of the bounding area of the element. • Mouse and touchpad both have an on-screen cursor that is always visible and fires this event even if no mouse or touchpad button is pressed. • Like touch, pen fires this event when moving out of the bounding area of the element. However, pen also has a hover state (IsInRange) that fires this event when the state changes from true to false.
PointerMoved	Occurs when a pointer changes coordinates, button state, pressure, tilt, or contact geometry (for example, width and height) within the bounding area of an element. This can happen in slightly different ways for touch, touchpad, mouse, and pen input. • Touch requires a finger contact and fires this event only when in contact within the bounding area of the element. • Mouse and touchpad both have an on-screen cursor that is always visible and fires this event even if no mouse or touchpad button is pressed. • Like touch, pen fires this event when in contact within the bounding area of the element. However, pen also has a hover state (IsInRange) that, when true and within the bounding area of the element, fires this event.

Event	Description
PointerPressed	Occurs when the pointer indicates a press action (such as a touch down, mouse button down, pen down, or touchpad button down) within the bounding area of an element. CapturePointer must be called from the handler for this event.
PointerReleased	Occurs when the pointer indicates a release action (such as a touch up, mouse button up, pen up, or touchpad button up) within the bounding area of an element or, if the pointer is captured, outside the bounding area.
PointerWheelChanged	Occurs when the mouse wheel is rotated. Mouse input is associated with a single pointer assigned when mouse input is first detected. Clicking a mouse button (left, wheel, or right) creates a secondary association between the pointer and that button through the PointerMoved event.

Pointer event example

Here are some code snippets from a basic pointer tracking app that show how to listen for and handle events for multiple pointers, and get various properties for the associated pointers.

Download this sample from Pointer input sample (basic)

Create the UI

For this example, we use a Rectangle (`Target`) as the object consuming pointer input. The color of the target changes when the pointer status changes.

Details for each pointer are displayed in a floating TextBlock that follows the pointer as it moves. The pointer events themselves are reported in the RichTextBlock to the right of the rectangle.

This is the Extensible Application Markup Language (XAML) for the UI in this example.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.ColumnDefinitions>
        <ColumnDefinition Width="*" />
        <ColumnDefinition Width="250"/>
    </Grid.ColumnDefinitions>
    <Grid.RowDefinitions>
        <RowDefinition Height="*" />
        <RowDefinition Height="320" />
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <Canvas Name="Container"
            Grid.Column="0"
            Grid.Row="1"
            HorizontalAlignment="Center"
            VerticalAlignment="Center"
            Margin="245,0"
```

```
            Height="320"  Width="640">
        <Rectangle Name="Target"
                   Fill="#FF0000"
                   Stroke="Black"
                   StrokeThickness="0"
                   Height="320" Width="640" />
    </Canvas>
    <Grid Grid.Column="1" Grid.Row="0" Grid.RowSpan="3">
        <Grid.RowDefinitions>
            <RowDefinition Height="50" />
            <RowDefinition Height="*" />
        </Grid.RowDefinitions>
        <Button Name="buttonClear"
                Grid.Row="0"
                Content="Clear"
                Foreground="White"
                HorizontalAlignment="Stretch"
                VerticalAlignment="Stretch">
        </Button>
        <ScrollViewer Name="eventLogScrollViewer" Grid.Row="1"
                      VerticalScrollMode="Auto"
                      Background="Black">
            <RichTextBlock Name="eventLog"
                      TextWrapping="Wrap"
                      Foreground="#FFFFFF"
                      ScrollViewer.VerticalScrollBarVisibility="Visible"

ScrollViewer.HorizontalScrollBarVisibility="Disabled"
                      Grid.ColumnSpan="2">
            </RichTextBlock>
        </ScrollViewer>
    </Grid>
</Grid>
```

Listen for pointer events

In most cases, we recommend that you get pointer info through the **PointerRoutedEventArgs** of the event handler.

If the event argument doesn't expose the pointer details required, you can get access to extended **PointerPoint** info exposed through the **GetCurrentPoint** and **GetIntermediatePoints** methods of **PointerRoutedEventArgs**.

The following code sets up the global dictionary object for tracking each active pointer, and identifies the various pointer event listeners for the target object.

CSharp

```
// Dictionary to maintain information about each active pointer.
// An entry is added during PointerPressed/PointerEntered events and removed
```

```
// during PointerReleased/PointerCaptureLost/PointerCanceled/PointerExited
events.
Dictionary<uint, Windows.UI.Xaml.Input.Pointer> pointers;

public MainPage()
{
    this.InitializeComponent();

    // Initialize the dictionary.
    pointers = new Dictionary<uint, Windows.UI.Xaml.Input.Pointer>();

    // Declare the pointer event handlers.
    Target.PointerPressed +=
        new PointerEventHandler(Target_PointerPressed);
    Target.PointerEntered +=
        new PointerEventHandler(Target_PointerEntered);
    Target.PointerReleased +=
        new PointerEventHandler(Target_PointerReleased);
    Target.PointerExited +=
        new PointerEventHandler(Target_PointerExited);
    Target.PointerCanceled +=
        new PointerEventHandler(Target_PointerCanceled);
    Target.PointerCaptureLost +=
        new PointerEventHandler(Target_PointerCaptureLost);
    Target.PointerMoved +=
        new PointerEventHandler(Target_PointerMoved);
    Target.PointerWheelChanged +=
        new PointerEventHandler(Target_PointerWheelChanged);

    buttonClear.Click +=
        new RoutedEventHandler(ButtonClear_Click);
}
```

Handle pointer events

Next, we use UI feedback to demonstrate basic pointer event handlers.

- This handler manages the **PointerPressed** event. We add the event to the event log, add the pointer to the active pointer dictionary, and display the pointer details.

  > **Note**
  >
  > **PointerPressed** and **PointerReleased** events do not always occur in pairs. Your app should listen for and handle any event that might conclude a pointer down (such as **PointerExited**, **PointerCanceled**, and **PointerCaptureLost**).

```
C#
```

```
/// <summary>
/// The pointer pressed event handler.
/// PointerPressed and PointerReleased don't always occur in pairs.
/// Your app should listen for and handle any event that can conclude
/// a pointer down (PointerExited, PointerCanceled, PointerCaptureLost).
/// </summary>
/// <param name="sender">Source of the pointer event.</param>
/// <param name="e">Event args for the pointer routed event.</param>
void Target_PointerPressed(object sender, PointerRoutedEventArgs e)
{
    // Prevent most handlers along the event route from handling the same
event again.
    e.Handled = true;

    PointerPoint ptrPt = e.GetCurrentPoint(Target);

    // Update event log.
    UpdateEventLog("Down: " + ptrPt.PointerId);

    // Lock the pointer to the target.
    Target.CapturePointer(e.Pointer);

    // Update event log.
    UpdateEventLog("Pointer captured: " + ptrPt.PointerId);

    // Check if pointer exists in dictionary (ie, enter occurred prior to
press).
    if (!pointers.ContainsKey(ptrPt.PointerId))
    {
        // Add contact to dictionary.
        pointers[ptrPt.PointerId] = e.Pointer;
    }

    // Change background color of target when pointer contact detected.
    Target.Fill = new SolidColorBrush(Windows.UI.Colors.Green);

    // Display pointer details.
    CreateInfoPop(ptrPt);
}
```

- This handler manages the **PointerEntered** event. We add the event to the event log, add the pointer to the pointer collection, and display the pointer details.

C#

```
/// <summary>
/// The pointer entered event handler.
/// We do not capture the pointer on this event.
/// </summary>
/// <param name="sender">Source of the pointer event.</param>
/// <param name="e">Event args for the pointer routed event.</param>
private void Target_PointerEntered(object sender, PointerRoutedEventArgs e)
```

```
{
    // Prevent most handlers along the event route from handling the same
event again.
    e.Handled = true;

    PointerPoint ptrPt = e.GetCurrentPoint(Target);

    // Update event log.
    UpdateEventLog("Entered: " + ptrPt.PointerId);

    // Check if pointer already exists (if enter occurred prior to down).
    if (!pointers.ContainsKey(ptrPt.PointerId))
    {
        // Add contact to dictionary.
        pointers[ptrPt.PointerId] = e.Pointer;
    }

    if (pointers.Count == 0)
    {
        // Change background color of target when pointer contact detected.
        Target.Fill = new SolidColorBrush(Windows.UI.Colors.Blue);
    }

    // Display pointer details.
    CreateInfoPop(ptrPt);
}
```

- This handler manages the **PointerMoved** event. We add the event to the event log and update the pointer details.

> **ⓘ Important**
>
> Mouse input is associated with a single pointer assigned when mouse input is first detected. Clicking a mouse button (left, wheel, or right) creates a secondary association between the pointer and that button through the **PointerPressed** event. The **PointerReleased** event is fired only when that same mouse button is released (no other button can be associated with the pointer until this event is complete). Because of this exclusive association, other mouse button clicks are routed through the **PointerMoved** event.

C#

```
/// <summary>
/// The pointer moved event handler.
/// </summary>
/// <param name="sender">Source of the pointer event.</param>
/// <param name="e">Event args for the pointer routed event.</param>
private void Target_PointerMoved(object sender, PointerRoutedEventArgs e)
{
```

```
    // Prevent most handlers along the event route from handling the same
event again.
    e.Handled = true;

    PointerPoint ptrPt = e.GetCurrentPoint(Target);

    // Multiple, simultaneous mouse button inputs are processed here.
    // Mouse input is associated with a single pointer assigned when
    // mouse input is first detected.
    // Clicking additional mouse buttons (left, wheel, or right) during
    // the interaction creates secondary associations between those buttons
    // and the pointer through the pointer pressed event.
    // The pointer released event is fired only when the last mouse button
    // associated with the interaction (not necessarily the initial button)
    // is released.
    // Because of this exclusive association, other mouse button clicks are
    // routed through the pointer move event.
    if (ptrPt.PointerDevice.PointerDeviceType ==
Windows.Devices.Input.PointerDeviceType.Mouse)
    {
        if (ptrPt.Properties.IsLeftButtonPressed)
        {
            UpdateEventLog("Left button: " + ptrPt.PointerId);
        }
        if (ptrPt.Properties.IsMiddleButtonPressed)
        {
            UpdateEventLog("Wheel button: " + ptrPt.PointerId);
        }
        if (ptrPt.Properties.IsRightButtonPressed)
        {
            UpdateEventLog("Right button: " + ptrPt.PointerId);
        }
    }

    // Display pointer details.
    UpdateInfoPop(ptrPt);
}
```

- This handler manages the **PointerWheelChanged** event. We add the event to the event log, add the pointer to the pointer array (if necessary), and display the pointer details.

C#

```
/// <summary>
/// The pointer wheel event handler.
/// </summary>
/// <param name="sender">Source of the pointer event.</param>
/// <param name="e">Event args for the pointer routed event.</param>
private void Target_PointerWheelChanged(object sender,
PointerRoutedEventArgs e)
{
```

```
    // Prevent most handlers along the event route from handling the same
event again.
    e.Handled = true;

    PointerPoint ptrPt = e.GetCurrentPoint(Target);

    // Update event log.
    UpdateEventLog("Mouse wheel: " + ptrPt.PointerId);

    // Check if pointer already exists (for example, enter occurred prior to
wheel).
    if (!pointers.ContainsKey(ptrPt.PointerId))
    {
        // Add contact to dictionary.
        pointers[ptrPt.PointerId] = e.Pointer;
    }

    // Display pointer details.
    CreateInfoPop(ptrPt);
}
```

- This handler manages the **PointerReleased** event where contact with the digitizer is terminated. We add the event to the event log, remove the pointer from the pointer collection, and update the pointer details.

C#

```
/// <summary>
/// The pointer released event handler.
/// PointerPressed and PointerReleased don't always occur in pairs.
/// Your app should listen for and handle any event that can conclude
/// a pointer down (PointerExited, PointerCanceled, PointerCaptureLost).
/// </summary>
/// <param name="sender">Source of the pointer event.</param>
/// <param name="e">Event args for the pointer routed event.</param>
void Target_PointerReleased(object sender, PointerRoutedEventArgs e)
{
    // Prevent most handlers along the event route from handling the same
event again.
    e.Handled = true;

    PointerPoint ptrPt = e.GetCurrentPoint(Target);

    // Update event log.
    UpdateEventLog("Up: " + ptrPt.PointerId);

    // If event source is mouse or touchpad and the pointer is still
    // over the target, retain pointer and pointer details.
    // Return without removing pointer from pointers dictionary.
    // For this example, we assume a maximum of one mouse pointer.
    if (ptrPt.PointerDevice.PointerDeviceType !=
Windows.Devices.Input.PointerDeviceType.Mouse)
```

```
    {
        // Update target UI.
        Target.Fill = new SolidColorBrush(Windows.UI.Colors.Red);

        DestroyInfoPop(ptrPt);

        // Remove contact from dictionary.
        if (pointers.ContainsKey(ptrPt.PointerId))
        {
            pointers[ptrPt.PointerId] = null;
            pointers.Remove(ptrPt.PointerId);
        }

        // Release the pointer from the target.
        Target.ReleasePointerCapture(e.Pointer);

        // Update event log.
        UpdateEventLog("Pointer released: " + ptrPt.PointerId);
    }
    else
    {
        Target.Fill = new SolidColorBrush(Windows.UI.Colors.Blue);
    }
}
```

- This handler manages the **PointerExited** event (when contact with the digitizer is maintained). We add the event to the event log, remove the pointer from the pointer array, and update the pointer details.

C#

```
/// <summary>
/// The pointer exited event handler.
/// </summary>
/// <param name="sender">Source of the pointer event.</param>
/// <param name="e">Event args for the pointer routed event.</param>
private void Target_PointerExited(object sender, PointerRoutedEventArgs e)
{
    // Prevent most handlers along the event route from handling the same
event again.
    e.Handled = true;

    PointerPoint ptrPt = e.GetCurrentPoint(Target);

    // Update event log.
    UpdateEventLog("Pointer exited: " + ptrPt.PointerId);

    // Remove contact from dictionary.
    if (pointers.ContainsKey(ptrPt.PointerId))
    {
        pointers[ptrPt.PointerId] = null;
        pointers.Remove(ptrPt.PointerId);
```

```
    }

    if (pointers.Count == 0)
    {
        Target.Fill = new SolidColorBrush(Windows.UI.Colors.Red);
    }

    // Update the UI and pointer details.
    DestroyInfoPop(ptrPt);
}
```

- This handler manages the **PointerCanceled** event. We add the event to the event log, remove the pointer from the pointer array, and update the pointer details.

C#

```
/// <summary>
/// The pointer canceled event handler.
/// Fires for various reasons, including:
///    - Touch contact canceled by pen coming into range of the surface.
///    - The device doesn't report an active contact for more than 100ms.
///    - The desktop is locked or the user logged off.
///    - The number of simultaneous contacts exceeded the number supported
by the device.
/// </summary>
/// <param name="sender">Source of the pointer event.</param>
/// <param name="e">Event args for the pointer routed event.</param>
private void Target_PointerCanceled(object sender, PointerRoutedEventArgs e)
{
    // Prevent most handlers along the event route from handling the same
event again.
    e.Handled = true;

    PointerPoint ptrPt = e.GetCurrentPoint(Target);

    // Update event log.
    UpdateEventLog("Pointer canceled: " + ptrPt.PointerId);

    // Remove contact from dictionary.
    if (pointers.ContainsKey(ptrPt.PointerId))
    {
        pointers[ptrPt.PointerId] = null;
        pointers.Remove(ptrPt.PointerId);
    }

    if (pointers.Count == 0)
    {
        Target.Fill = new SolidColorBrush(Windows.UI.Colors.Black);
    }

    DestroyInfoPop(ptrPt);
}
```

- This handler manages the **PointerCaptureLost** event. We add the event to the event log, remove the pointer from the pointer array, and update the pointer details.

> **Note**
>
> **PointerCaptureLost** can occur instead of **PointerReleased**. Pointer capture can be lost for various reasons including user interaction, programmatic capture of another pointer, calling **PointerReleased**.

C#

```
/// <summary>
/// The pointer capture lost event handler.
/// Fires for various reasons, including:
///    - User interactions
///    - Programmatic capture of another pointer
///    - Captured pointer was deliberately released
// PointerCaptureLost can fire instead of PointerReleased.
/// </summary>
/// <param name="sender">Source of the pointer event.</param>
/// <param name="e">Event args for the pointer routed event.</param>
private void Target_PointerCaptureLost(object sender, PointerRoutedEventArgs
e)
{
    // Prevent most handlers along the event route from handling the same
event again.
    e.Handled = true;

    PointerPoint ptrPt = e.GetCurrentPoint(Target);

    // Update event log.
    UpdateEventLog("Pointer capture lost: " + ptrPt.PointerId);

    if (pointers.Count == 0)
    {
        Target.Fill = new SolidColorBrush(Windows.UI.Colors.Black);
    }

    // Remove contact from dictionary.
    if (pointers.ContainsKey(ptrPt.PointerId))
    {
        pointers[ptrPt.PointerId] = null;
        pointers.Remove(ptrPt.PointerId);
    }

    DestroyInfoPop(ptrPt);
}
```

Get pointer properties

As stated earlier, you must get most extended pointer info from a Windows.UI.Input.PointerPoint object obtained through the GetCurrentPoint and GetIntermediatePoints methods of PointerRoutedEventArgs. The following code snippets show how.

- First, we create a new TextBlock for each pointer.

C#

```
/// <summary>
/// Create the pointer info popup.
/// </summary>
/// <param name="ptrPt">Reference to the input pointer.</param>
void CreateInfoPop(PointerPoint ptrPt)
{
    TextBlock pointerDetails = new TextBlock();
    pointerDetails.Name = ptrPt.PointerId.ToString();
    pointerDetails.Foreground = new
SolidColorBrush(Windows.UI.Colors.White);
    pointerDetails.Text = QueryPointer(ptrPt);

    TranslateTransform x = new TranslateTransform();
    x.X = ptrPt.Position.X + 20;
    x.Y = ptrPt.Position.Y + 20;
    pointerDetails.RenderTransform = x;

    Container.Children.Add(pointerDetails);
}
```

- Then we provide a way to update the pointer info in an existing TextBlock associated with that pointer.

C#

```
/// <summary>
/// Update the pointer info popup.
/// </summary>
/// <param name="ptrPt">Reference to the input pointer.</param>
void UpdateInfoPop(PointerPoint ptrPt)
{
    foreach (var pointerDetails in Container.Children)
    {
        if (pointerDetails.GetType().ToString() ==
"Windows.UI.Xaml.Controls.TextBlock")
        {
            TextBlock textBlock = (TextBlock)pointerDetails;
            if (textBlock.Name == ptrPt.PointerId.ToString())
            {
```

```
                // To get pointer location details, we need extended pointer
info.
                // We get the pointer info through the getCurrentPoint
method
                // of the event argument.
                TranslateTransform x = new TranslateTransform();
                x.X = ptrPt.Position.X + 20;
                x.Y = ptrPt.Position.Y + 20;
                pointerDetails.RenderTransform = x;
                textBlock.Text = QueryPointer(ptrPt);
            }
        }
    }
}
```

- Finally, we query various pointer properties.

C#

```
/// <summary>
/// Get pointer details.
/// </summary>
/// <param name="ptrPt">Reference to the input pointer.</param>
/// <returns>A string composed of pointer details.</returns>
String QueryPointer(PointerPoint ptrPt)
{
    String details = "";

    switch (ptrPt.PointerDevice.PointerDeviceType)
    {
        case Windows.Devices.Input.PointerDeviceType.Mouse:
            details += "\nPointer type: mouse";
            break;
        case Windows.Devices.Input.PointerDeviceType.Pen:
            details += "\nPointer type: pen";
            if (ptrPt.IsInContact)
            {
                details += "\nPressure: " + ptrPt.Properties.Pressure;
                details += "\nrotation: " + ptrPt.Properties.Orientation;
                details += "\nTilt X: " + ptrPt.Properties.XTilt;
                details += "\nTilt Y: " + ptrPt.Properties.YTilt;
                details += "\nBarrel button pressed: " +
ptrPt.Properties.IsBarrelButtonPressed;
            }
            break;
        case Windows.Devices.Input.PointerDeviceType.Touch:
            details += "\nPointer type: touch";
            details += "\nrotation: " + ptrPt.Properties.Orientation;
            details += "\nTilt X: " + ptrPt.Properties.XTilt;
            details += "\nTilt Y: " + ptrPt.Properties.YTilt;
            break;
        default:
            details += "\nPointer type: n/a";
```

```
            break;
    }

    GeneralTransform gt = Target.TransformToVisual(this);
    Point screenPoint;

    screenPoint = gt.TransformPoint(new Point(ptrPt.Position.X,
ptrPt.Position.Y));
    details += "\nPointer Id: " + ptrPt.PointerId.ToString() +
        "\nPointer location (target): " + Math.Round(ptrPt.Position.X) + ",
" + Math.Round(ptrPt.Position.Y) +
        "\nPointer location (container): " + Math.Round(screenPoint.X) + ",
" + Math.Round(screenPoint.Y);

    return details;
}
```

Primary pointer

Some input devices, such as a touch digitizer or touchpad, support more than the typical single pointer of a mouse or a pen (in most cases as the Surface Hub supports two pen inputs).

Use the read-only **IsPrimary** property of the **PointerPointerProperties** class to identify and differentiate a single primary pointer (the primary pointer is always the first pointer detected during an input sequence).

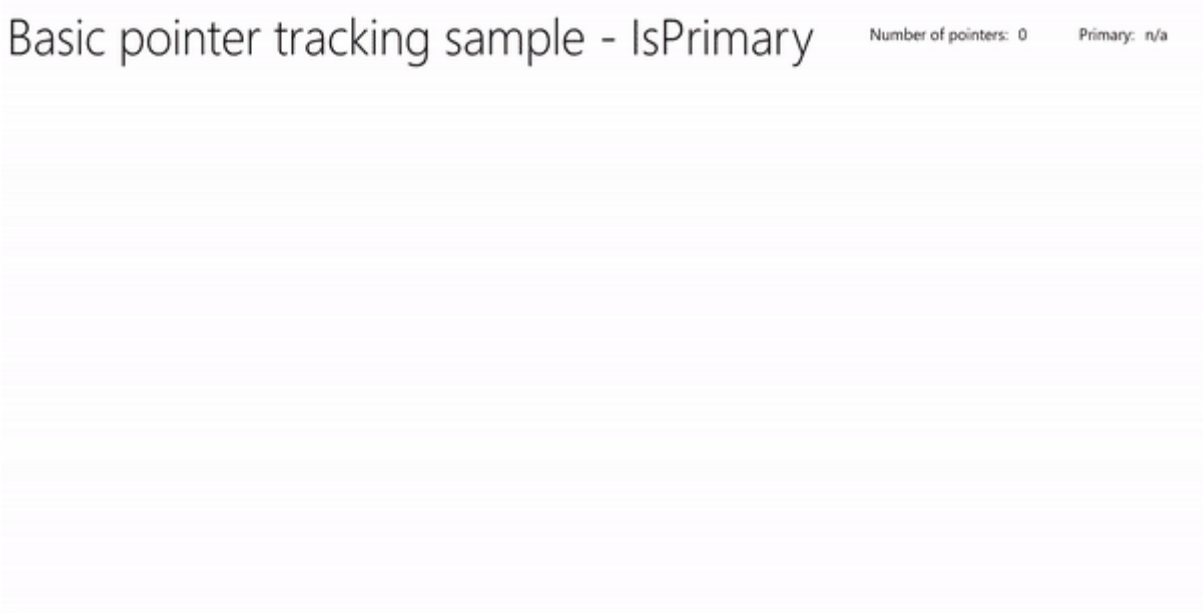
By identifying the primary pointer, you can use it to emulate mouse or pen input, customize interactions, or provide some other specific functionality or UI.

> **Note**
>
> If the primary pointer is released, canceled, or lost during an input sequence, a primary input pointer is not created until a new input sequence is initiated (an input sequence ends when all pointers have been released, canceled, or lost).

Primary pointer animation example

These code snippets show how you can provide special visual feedback to help a user differentiate between pointer inputs in your application.

This particular app uses both color and animation to highlight the primary pointer.



Download this sample from Pointer input sample (UserControl with animation)

Visual feedback

We define a **UserControl**, based on a XAML **Ellipse** object, that highlights where each pointer is on the canvas and uses a **Storyboard** to animate the ellipse that corresponds to the primary pointer.

Here's the XAML:

XAML

```
<UserControl
    x:Class="UWP_Pointers.PointerEllipse"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:local="using:UWP_Pointers"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    mc:Ignorable="d"
    d:DesignHeight="100"
    d:DesignWidth="100">

    <UserControl.Resources>
        <Style x:Key="EllipseStyle" TargetType="Ellipse">
            <Setter Property="Transitions">
                <Setter.Value>
                    <TransitionCollection>
                        <ContentThemeTransition/>
                    </TransitionCollection>
                </Setter.Value>
            </Setter>
        </Style>
```

```
        <Storyboard x:Name="myStoryboard">
            <!-- Animates the value of a Double property between
            two target values using linear interpolation over the
            specified Duration. -->
            <DoubleAnimation
              Storyboard.TargetName="ellipse"
              Storyboard.TargetProperty="(RenderTransform).
(ScaleTransform.ScaleY)"
              Duration="0:0:1"
              AutoReverse="True"
              RepeatBehavior="Forever" From="1.0" To="1.4">
            </DoubleAnimation>

            <!-- Animates the value of a Double property between
            two target values using linear interpolation over the
            specified Duration. -->
            <DoubleAnimation
              Storyboard.TargetName="ellipse"
              Storyboard.TargetProperty="(RenderTransform).
(ScaleTransform.ScaleX)"
              Duration="0:0:1"
              AutoReverse="True"
              RepeatBehavior="Forever" From="1.0" To="1.4">
            </DoubleAnimation>

            <!-- Animates the value of a Color property between
            two target values using linear interpolation over the
            specified Duration. -->
            <ColorAnimation
                Storyboard.TargetName="ellipse"
                EnableDependentAnimation="True"
                Storyboard.TargetProperty="(Fill).(SolidColorBrush.Color)"
                From="White" To="Red"  Duration="0:0:1"
                AutoReverse="True" RepeatBehavior="Forever"/>
        </Storyboard>
    </UserControl.Resources>

    <Grid x:Name="CompositionContainer">
        <Ellipse Name="ellipse"
        StrokeThickness="2"
        Width="{x:Bind Diameter}"
        Height="{x:Bind Diameter}"
        Style="{StaticResource EllipseStyle}" />
    </Grid>
</UserControl>
```

And here's the code-behind:

C#

```
using Windows.Foundation;
using Windows.UI.Xaml;
using Windows.UI.Xaml.Controls;
```

```
using Windows.UI.Xaml.Media;

// The User Control item template is documented at
// https://go.microsoft.com/fwlink/?LinkId=234236

                    ellipse.RenderTransform = new CompositeTransform();
                    ellipse.RenderTransformOrigin = new Point(.5, .5);
                    myStoryboard.Begin();
                }
                else
                {
                    SolidColorBrush fillBrush =

(SolidColorBrush)Application.Current.Resources["SecondaryFillBrush"];
                    SolidColorBrush strokeBrush =

(SolidColorBrush)Application.Current.Resources["SecondaryStrokeBrush"];
                    ellipse.Fill = fillBrush;
                    ellipse.Stroke = strokeBrush;
                }
            }
        }
        // Using a DependencyProperty as the backing store for
PrimaryEllipse.
        // This enables animation, styling, binding, etc...
        public static readonly DependencyProperty PrimaryEllipseProperty =
            DependencyProperty.Register("PrimaryEllipse",
                typeof(bool), typeof(PointerEllipse), new
PropertyMetadata(false));

        /// <summary>
        /// Gets or sets the diameter of the PointerEllipse object.
        /// </summary>
```

```
        public int Diameter
        {
            get { return (int)GetValue(DiameterProperty); }
            set { SetValue(DiameterProperty, value); }
        }
        // Using a DependencyProperty as the backing store for Diameter.
This enables animation, styling, binding, etc...
        public static readonly DependencyProperty DiameterProperty =
            DependencyProperty.Register("Diameter", typeof(int),
                typeof(PointerEllipse), new PropertyMetadata(120));
    }
}
```

Create the UI

The UI in this example is limited to the input **Canvas** where we track any pointers and render the pointer indicators and primary pointer animation (if applicable), along with a header bar containing a pointer counter and a primary pointer identifier.

Here's the MainPage.xaml:

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel x:Name="HeaderPanel"
                Orientation="Horizontal"
                Grid.Row="0">
        <StackPanel.Transitions>
            <TransitionCollection>
                <AddDeleteThemeTransition/>
            </TransitionCollection>
        </StackPanel.Transitions>
        <TextBlock x:Name="Header"
                   Text="Basic pointer tracking sample - IsPrimary"
                   Style="{ThemeResource HeaderTextBlockStyle}"
                   Margin="10,0,0,0" />
        <TextBlock x:Name="PointerCounterLabel"
                   VerticalAlignment="Center"
                   Style="{ThemeResource BodyTextBlockStyle}"
                   Text="Number of pointers: "
                   Margin="50,0,0,0"/>
        <TextBlock x:Name="PointerCounter"
                   VerticalAlignment="Center"
                   Style="{ThemeResource BodyTextBlockStyle}"
                   Text="0"
                   Margin="10,0,0,0"/>
        <TextBlock x:Name="PointerPrimaryLabel"
```

```
                    VerticalAlignment="Center"
                    Style="{ThemeResource BodyTextBlockStyle}"
                    Text="Primary: "
                    Margin="50,0,0,0"/>
        <TextBlock x:Name="PointerPrimary"
                    VerticalAlignment="Center"
                    Style="{ThemeResource BodyTextBlockStyle}"
                    Text="n/a"
                    Margin="10,0,0,0"/>
    </StackPanel>

    <Grid Grid.Row="1">
        <!--The canvas where we render the pointer UI.-->
        <Canvas x:Name="pointerCanvas"/>
    </Grid>
</Grid>
```

Handle pointer events

Finally, we define our basic pointer event handlers in the MainPage.xaml.cs code-behind. We won't reproduce the code here as the basics were covered in the previous example, but you can download the working sample from Pointer input sample (UserControl with animation).

Gaze interactions and eye tracking in Windows apps

Article • 05/24/2022

Provide support for tracking a user's gaze, attention, and presence based on the location and movement of their eyes.

> **Note**
>
> For gaze input in Windows Mixed Reality, see [Gaze]/windows/mixed-reality/mrtk-unity/features/input/gaze).

Important APIs: Windows.Devices.Input.Preview, GazeDevicePreview, GazePointPreview, GazeInputSourcePreview

Overview

Gaze input is a powerful way to interact and use Windows applications that is especially useful as an assistive technology for users with neuro-muscular diseases (such as ALS) and other disabilities involving impaired muscle or nerve functions.

In addition, gaze input offers equally compelling opportunities for both gaming (including target acquisition and tracking) and traditional productivity applications, kiosks, and other interactive scenarios where traditional input devices (keyboard, mouse, touch) are not available, or where it might be useful/helpful to free up the user's hands for other tasks (such as holding shopping bags).

> **Note**

Support for eye tracking hardware was introduced in **Windows 10 Fall Creators Update** along with Eye control, a built-in feature that lets you use your eyes to control the on-screen pointer, type with the on-screen keyboard, and communicate with people using text-to-speech. A set of Windows Runtime APIs (Windows.Devices.Input.Preview) for building applications that can interact with eye tracking hardware is available with **Windows 10 April 2018 Update (Version 1803, build 17134)** and newer.

Privacy

Due to the potentially sensitive personal data collected by eye tracking devices, you are required to declare the `gazeInput` capability in the app manifest of your application (see the following **Setup** section). When declared, Windows automatically prompts users with a consent dialog (when the app is first run), where the user must grant permission for the app to communicate with the eye-tracking device and access this data.

In addition, if your app collects, stores, or transfers eye tracking data, you must describe this in your app's privacy statement and follow all other requirements for **Personal Information** in the App Developer Agreement and the Microsoft Store Policies.

Setup

To use the gaze input APIs in your Windows app you'll need to:

- Specify the `gazeInput` capability in the app manifest.

  Open the **Package.appxmanifest** file with the Visual Studio manifest designer, or add the capability manually by selecting **View code**, and inserting the following `DeviceCapability` into the `Capabilities` node:

  XAML

  ```
  <Capabilities>
     <DeviceCapability Name="gazeInput" />
  </Capabilities>
  ```

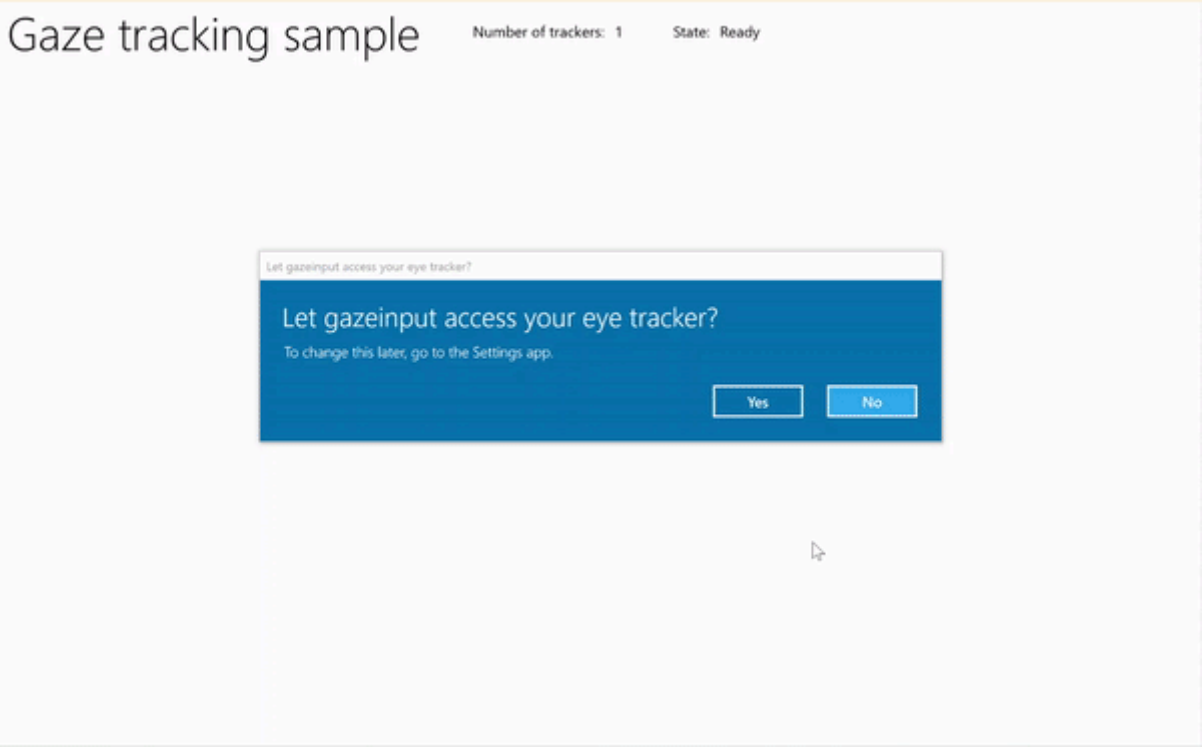
- A Windows-compatible eye-tracking device connected to your system (either built-in or peripheral) and turned on.

  See Get started with eye control in Windows 10 for a list of supported eye-tracking devices.

Basic eye tracking

In this example, we demonstrate how to track the user's gaze within a Windows app and use a timing function with basic hit testing to indicate how well they can maintain their gaze focus on a specific element.

A small ellipse is used to show where the gaze point is within the application viewport, while a RadialProgressBar from the Windows Community Toolkit is placed randomly on the canvas. When gaze focus is detected on the progress bar, a timer is started and the progress bar is randomly relocated on the canvas when the progress bar reaches 100%.



Gaze tracking with timer sample

Download this sample from Gaze input sample (basic)

1. First, we set up the UI (MainPage.xaml).

XAML

```
<Page
    x:Class="gazeinput.MainPage"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:local="using:gazeinput"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-
compatibility/2006"
    xmlns:controls="using:Microsoft.Toolkit.Uwp.UI.Controls"
    mc:Ignorable="d">
```

```
    <Grid Background="{ThemeResource
ApplicationPageBackgroundThemeBrush}">
        <Grid x:Name="containerGrid">
            <Grid.RowDefinitions>
                <RowDefinition Height="Auto"/>
                <RowDefinition Height="*"/>
            </Grid.RowDefinitions>
            <StackPanel x:Name="HeaderPanel"
                    Orientation="Horizontal"
                    Grid.Row="0">
                <StackPanel.Transitions>
                    <TransitionCollection>
                        <AddDeleteThemeTransition/>
                    </TransitionCollection>
                </StackPanel.Transitions>
                <TextBlock x:Name="Header"
                       Text="Gaze tracking sample"
                       Style="{ThemeResource HeaderTextBlockStyle}"
                       Margin="10,0,0,0" />
                <TextBlock x:Name="TrackerCounterLabel"
                       VerticalAlignment="Center"
                       Style="{ThemeResource BodyTextBlockStyle}"
                       Text="Number of trackers: "
                       Margin="50,0,0,0"/>
                <TextBlock x:Name="TrackerCounter"
                       VerticalAlignment="Center"
                       Style="{ThemeResource BodyTextBlockStyle}"
                       Text="0"
                       Margin="10,0,0,0"/>
                <TextBlock x:Name="TrackerStateLabel"
                       VerticalAlignment="Center"
                       Style="{ThemeResource BodyTextBlockStyle}"
                       Text="State: "
                       Margin="50,0,0,0"/>
                <TextBlock x:Name="TrackerState"
                       VerticalAlignment="Center"
                       Style="{ThemeResource BodyTextBlockStyle}"
                       Text="n/a"
                       Margin="10,0,0,0"/>
            </StackPanel>
            <Canvas x:Name="gazePositionCanvas" Grid.Row="1">
                <controls:RadialProgressBar
                    x:Name="GazeRadialProgressBar"
                    Value="0"
                    Foreground="Blue"
                    Background="White"
                    Thickness="4"
                    Minimum="0"
                    Maximum="100"
                    Width="100"
                    Height="100"
                    Outline="Gray"
                    Visibility="Collapsed"/>
                <Ellipse
                    x:Name="eyeGazePositionEllipse"
```

```
                    Width="20" Height="20"
                    Fill="Blue"
                    Opacity="0.5"
                    Visibility="Collapsed">
                </Ellipse>
            </Canvas>
        </Grid>
    </Grid>
</Page>
```

2. Next, we initialize our app.

   In this snippet, we declare our global objects and override the OnNavigatedTo page event to start our gaze device watcher and the OnNavigatedFrom page event to stop our gaze device watcher.

C#

```
using System;
using Windows.Devices.Input.Preview;
using Windows.UI.Xaml.Controls;
using Windows.UI.Xaml;
using Windows.Foundation;
using System.Collections.Generic;
using Windows.UI.Xaml.Media;
using Windows.UI.Xaml.Navigation;

namespace gazeinput
{
    public sealed partial class MainPage : Page
    {
        /// <summary>
        /// Reference to the user's eyes and head as detected
        /// by the eye-tracking device.
        /// </summary>
        private GazeInputSourcePreview gazeInputSource;

        /// <summary>
        /// Dynamic store of eye-tracking devices.
        /// </summary>
        /// <remarks>
        /// Receives event notifications when a device is added,
removed,
        /// or updated after the initial enumeration.
        /// </remarks>
        private GazeDeviceWatcherPreview gazeDeviceWatcher;

        /// <summary>
        /// Eye-tracking device counter.
        /// </summary>
        private int deviceCounter = 0;
```

```
        /// <summary>
        /// Timer for gaze focus on RadialProgressBar.
        /// </summary>
        DispatcherTimer timerGaze = new DispatcherTimer();

        /// <summary>
        /// Tracker used to prevent gaze timer restarts.
        /// </summary>
        bool timerStarted = false;

        /// <summary>
        /// Initialize the app.
        /// </summary>
        public MainPage()
        {
            InitializeComponent();
        }

        /// <summary>
        /// Override of OnNavigatedTo page event starts
GazeDeviceWatcher.
        /// </summary>
        /// <param name="e">Event args for the NavigatedTo
event</param>
        protected override void OnNavigatedTo(NavigationEventArgs e)
        {
            // Start listening for device events on navigation to eye-
tracking page.
            StartGazeDeviceWatcher();
        }

        /// <summary>
        /// Override of OnNavigatedFrom page event stops
GazeDeviceWatcher.
        /// </summary>
        /// <param name="e">Event args for the NavigatedFrom
event</param>
        protected override void OnNavigatedFrom(NavigationEventArgs e)
        {
            // Stop listening for device events on navigation from eye-
tracking page.
            StopGazeDeviceWatcher();
        }
    }
}
```

3. Next, we add our gaze device watcher methods.

   In `StartGazeDeviceWatcher`, we call CreateWatcher and declare the eye-tracking device event listeners (DeviceAdded, DeviceUpdated, and DeviceRemoved).

In `DeviceAdded`, we check the state of the eye-tracking device. If a viable device, we increment our device count and enable gaze tracking. See next step for details.

In `DeviceUpdated`, we also enable gaze tracking as this event is triggered if a device is recalibrated.

In `DeviceRemoved`, we decrement our device counter and remove the device event handlers.

In `StopGazeDeviceWatcher`, we shut down the gaze device watcher.

C#

```
    /// <summary>
    /// Start gaze watcher and declare watcher event handlers.
    /// </summary>
    private void StartGazeDeviceWatcher()
    {
        if (gazeDeviceWatcher == null)
        {
            gazeDeviceWatcher = GazeInputSourcePreview.CreateWatcher();
            gazeDeviceWatcher.Added += this.DeviceAdded;
            gazeDeviceWatcher.Updated += this.DeviceUpdated;
            gazeDeviceWatcher.Removed += this.DeviceRemoved;
            gazeDeviceWatcher.Start();
        }
    }

    /// <summary>
    /// Shut down gaze watcher and stop listening for events.
    /// </summary>
    private void StopGazeDeviceWatcher()
    {
        if (gazeDeviceWatcher != null)
        {
            gazeDeviceWatcher.Stop();
            gazeDeviceWatcher.Added -= this.DeviceAdded;
            gazeDeviceWatcher.Updated -= this.DeviceUpdated;
            gazeDeviceWatcher.Removed -= this.DeviceRemoved;
            gazeDeviceWatcher = null;
        }
    }

    /// <summary>
    /// Eye-tracking device connected (added, or available when watcher is
initialized).
    /// </summary>
    /// <param name="sender">Source of the device added event</param>
    /// <param name="e">Event args for the device added event</param>
    private void DeviceAdded(GazeDeviceWatcherPreview source,
        GazeDeviceWatcherAddedPreviewEventArgs args)
    {
```

```
        if (IsSupportedDevice(args.Device))
        {
            deviceCounter++;
            TrackerCounter.Text = deviceCounter.ToString();
        }
        // Set up gaze tracking.
        TryEnableGazeTrackingAsync(args.Device);
    }

    /// <summary>
    /// Initial device state might be uncalibrated,
    /// but device was subsequently calibrated.
    /// </summary>
    /// <param name="sender">Source of the device updated event</param>
    /// <param name="e">Event args for the device updated event</param>
    private void DeviceUpdated(GazeDeviceWatcherPreview source,
        GazeDeviceWatcherUpdatedPreviewEventArgs args)
    {
        // Set up gaze tracking.
        TryEnableGazeTrackingAsync(args.Device);
    }

    /// <summary>
    /// Handles disconnection of eye-tracking devices.
    /// </summary>
    /// <param name="sender">Source of the device removed event</param>
    /// <param name="e">Event args for the device removed event</param>
    private void DeviceRemoved(GazeDeviceWatcherPreview source,
        GazeDeviceWatcherRemovedPreviewEventArgs args)
    {
        // Decrement gaze device counter and remove event handlers.
        if (IsSupportedDevice(args.Device))
        {
            deviceCounter--;
            TrackerCounter.Text = deviceCounter.ToString();

            if (deviceCounter == 0)
            {
                gazeInputSource.GazeEntered -= this.GazeEntered;
                gazeInputSource.GazeMoved -= this.GazeMoved;
                gazeInputSource.GazeExited -= this.GazeExited;
            }
        }
    }
```

4. Here, we check if the device is viable in `IsSupportedDevice` and, if so, attempt to enable gaze tracking in `TryEnableGazeTrackingAsync`.

   In `TryEnableGazeTrackingAsync`, we declare the gaze event handlers, and call GazeInputSourcePreview.GetForCurrentView() to get a reference to the input source (this must be called on the UI thread, see Keep the UI thread responsive).

> **Note**
>
> You should call GazeInputSourcePreview.GetForCurrentView() only when a compatible eye-tracking device is connected and required by your application. Otherwise, the consent dialog is unnecessary.

C#

```
    /// <summary>
    /// Initialize gaze tracking.
    /// </summary>
    /// <param name="gazeDevice"></param>
    private async void TryEnableGazeTrackingAsync(GazeDevicePreview
gazeDevice)
    {
        // If eye-tracking device is ready, declare event handlers and start
tracking.
        if (IsSupportedDevice(gazeDevice))
        {
            timerGaze.Interval = new TimeSpan(0, 0, 0, 0, 20);
            timerGaze.Tick += TimerGaze_Tick;

            SetGazeTargetLocation();

            // This must be called from the UI thread.
            gazeInputSource = GazeInputSourcePreview.GetForCurrentView();

            gazeInputSource.GazeEntered += GazeEntered;
            gazeInputSource.GazeMoved += GazeMoved;
            gazeInputSource.GazeExited += GazeExited;
        }
        // Notify if device calibration required.
        else if (gazeDevice.ConfigurationState ==

GazeDeviceConfigurationStatePreview.UserCalibrationNeeded ||
                    gazeDevice.ConfigurationState ==
                    GazeDeviceConfigurationStatePreview.ScreenSetupNeeded)
        {
            // Device isn't calibrated, so invoke the calibration handler.
            System.Diagnostics.Debug.WriteLine(
                "Your device needs to calibrate. Please wait for it to
finish.");
            await gazeDevice.RequestCalibrationAsync();
        }
        // Notify if device calibration underway.
        else if (gazeDevice.ConfigurationState ==
            GazeDeviceConfigurationStatePreview.Configuring)
        {
            // Device is currently undergoing calibration.
            // A device update is sent when calibration complete.
            System.Diagnostics.Debug.WriteLine(
```

```
                "Your device is being configured. Please wait for it to
finish");
        }
        // Device is not viable.
        else if (gazeDevice.ConfigurationState ==
GazeDeviceConfigurationStatePreview.Unknown)
        {
            // Notify if device is in unknown state.
            // Reconfigure/recalbirate the device.
            System.Diagnostics.Debug.WriteLine(
                "Your device is not ready. Please set up your device or
reconfigure it.");
        }
    }

    /// <summary>
    /// Check if eye-tracking device is viable.
    /// </summary>
    /// <param name="gazeDevice">Reference to eye-tracking device.</param>
    /// <returns>True, if device is viable; otherwise, false.</returns>
    private bool IsSupportedDevice(GazeDevicePreview gazeDevice)
    {
        TrackerState.Text = gazeDevice.ConfigurationState.ToString();
        return (gazeDevice.CanTrackEyes &&
                    gazeDevice.ConfigurationState ==
                    GazeDeviceConfigurationStatePreview.Ready);
    }
```

5. Next, we set up our gaze event handlers.

   We display and hide the gaze tracking ellipse in `GazeEntered` and `GazeExited`, respectively.

   In `GazeMoved`, we move our gaze tracking ellipse based on the EyeGazePosition provided by the CurrentPoint of the GazeEnteredPreviewEventArgs. We also manage the gaze focus timer on the RadialProgressBar, which triggers repositioning of the progress bar. See next step for details.

   C#

```
/// <summary>
/// GazeEntered handler.
/// </summary>
/// <param name="sender">Source of the gaze entered event</param>
/// <param name="e">Event args for the gaze entered event</param>
private void GazeEntered(
    GazeInputSourcePreview sender,
    GazeEnteredPreviewEventArgs args)
{
    // Show ellipse representing gaze point.
    eyeGazePositionEllipse.Visibility = Visibility.Visible;
```

```
    // Mark the event handled.
    args.Handled = true;
}

/// <summary>
/// GazeExited handler.
/// Call DisplayRequest.RequestRelease to conclude the
/// RequestActive called in GazeEntered.
/// </summary>
/// <param name="sender">Source of the gaze exited event</param>
/// <param name="e">Event args for the gaze exited event</param>
private void GazeExited(
    GazeInputSourcePreview sender,
    GazeExitedPreviewEventArgs args)
{
    // Hide gaze tracking ellipse.
    eyeGazePositionEllipse.Visibility = Visibility.Collapsed;

    // Mark the event handled.
    args.Handled = true;
}

/// <summary>
/// GazeMoved handler translates the ellipse on the canvas to reflect
gaze point.
/// </summary>
/// <param name="sender">Source of the gaze moved event</param>
/// <param name="e">Event args for the gaze moved event</param>
private void GazeMoved(GazeInputSourcePreview sender,
GazeMovedPreviewEventArgs args)
{
    // Update the position of the ellipse corresponding to gaze point.
    if (args.CurrentPoint.EyeGazePosition != null)
    {
        double gazePointX = args.CurrentPoint.EyeGazePosition.Value.X;
        double gazePointY = args.CurrentPoint.EyeGazePosition.Value.Y;

        double ellipseLeft =
            gazePointX -
            (eyeGazePositionEllipse.Width / 2.0f);
        double ellipseTop =
            gazePointY -
            (eyeGazePositionEllipse.Height / 2.0f) -
            (int)Header.ActualHeight;

        // Translate transform for moving gaze ellipse.
        TranslateTransform translateEllipse = new TranslateTransform
        {
            X = ellipseLeft,
            Y = ellipseTop
        };

        eyeGazePositionEllipse.RenderTransform = translateEllipse;
```

```
        // The gaze point screen location.
        Point gazePoint = new Point(gazePointX, gazePointY);

        // Basic hit test to determine if gaze point is on progress
bar.
        bool hitRadialProgressBar =
            DoesElementContainPoint(
                gazePoint,
                GazeRadialProgressBar.Name,
                GazeRadialProgressBar);

        // Use progress bar thickness for visual feedback.
        if (hitRadialProgressBar)
        {
            GazeRadialProgressBar.Thickness = 10;
        }
        else
        {
            GazeRadialProgressBar.Thickness = 4;
        }

        // Mark the event handled.
        args.Handled = true;
    }
}
```

6. Finally, here are the methods used to manage the gaze focus timer for this app.

`DoesElementContainPoint` checks if the gaze pointer is over the progress bar. If so, it starts the gaze timer and increments the progress bar on each gaze timer tick.

`SetGazeTargetLocation` sets the initial location of the progress bar and, if the progress bar completes (depending on the gaze focus timer), moves the progress bar to a random location.

C#

```
/// <summary>
/// Return whether the gaze point is over the progress bar.
/// </summary>
/// <param name="gazePoint">The gaze point screen location</param>
/// <param name="elementName">The progress bar name</param>
/// <param name="uiElement">The progress bar UI element</param>
/// <returns></returns>
private bool DoesElementContainPoint(
    Point gazePoint, string elementName, UIElement uiElement)
{
    // Use entire visual tree of progress bar.
    IEnumerable<UIElement> elementStack =
        VisualTreeHelper.FindElementsInHostCoordinates(gazePoint,
uiElement, true);
    foreach (UIElement item in elementStack)
```

```
    {
        //Cast to FrameworkElement and get element name.
        if (item is FrameworkElement feItem)
        {
            if (feItem.Name.Equals(elementName))
            {
                if (!timerStarted)
                {
                    // Start gaze timer if gaze over element.
                    timerGaze.Start();
                    timerStarted = true;
                }
                return true;
            }
        }
    }

    // Stop gaze timer and reset progress bar if gaze leaves element.
    timerGaze.Stop();
    GazeRadialProgressBar.Value = 0;
    timerStarted = false;
    return false;
}

/// <summary>
/// Tick handler for gaze focus timer.
/// </summary>
/// <param name="sender">Source of the gaze entered event</param>
/// <param name="e">Event args for the gaze entered event</param>
private void TimerGaze_Tick(object sender, object e)
{
    // Increment progress bar.
    GazeRadialProgressBar.Value += 1;

    // If progress bar reaches maximum value, reset and relocate.
    if (GazeRadialProgressBar.Value == 100)
    {
        SetGazeTargetLocation();
    }
}

/// <summary>
/// Set/reset the screen location of the progress bar.
/// </summary>
private void SetGazeTargetLocation()
{
    // Ensure the gaze timer restarts on new progress bar location.
    timerGaze.Stop();
    timerStarted = false;

    // Get the bounding rectangle of the app window.
    Rect appBounds =
Windows.UI.ViewManagement.ApplicationView.GetForCurrentView().VisibleBo
unds;
```

```
    // Translate transform for moving progress bar.
    TranslateTransform translateTarget = new TranslateTransform();

    // Calculate random location within gaze canvas.
        Random random = new Random();
        int randomX =
            random.Next(
                0,
                (int)appBounds.Width -
(int)GazeRadialProgressBar.Width);
        int randomY =
            random.Next(
                0,
                (int)appBounds.Height -
(int)GazeRadialProgressBar.Height - (int)Header.ActualHeight);

    translateTarget.X = randomX;
    translateTarget.Y = randomY;

    GazeRadialProgressBar.RenderTransform = translateTarget;

    // Show progress bar.
    GazeRadialProgressBar.Visibility = Visibility.Visible;
    GazeRadialProgressBar.Value = 0;
}
```

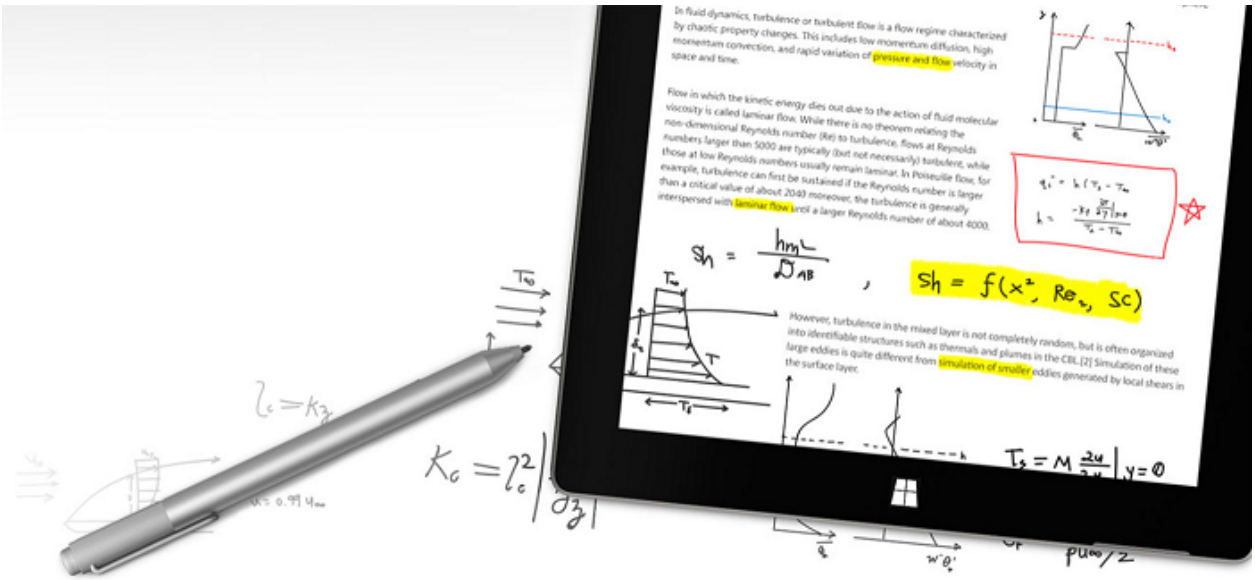
Pen interactions and Windows Ink in Windows apps

Article • 12/15/2021



Surface Pen (available for purchase at the Microsoft Store).

Overview

Optimize your Windows app for pen input to provide both standard **pointer device** functionality and the best Windows Ink experience for your users.

> **Note**
>
> This topic focuses on the Windows Ink platform. For general pointer input handling (similar to mouse, touch, and touchpad), see **Handle pointer input**.

Using ink in your Windows app

Use Windows Pen and Ink to build more engaging enterprise apps

The Windows Ink platform, together with a pen device, provides a natural way to create digital handwritten notes, drawings, and annotations. The platform supports capturing digitizer input as ink data, generating ink data, managing ink data, rendering ink data as ink strokes on the output device, and converting ink to text through handwriting recognition.

In addition to capturing the basic position and movement of the pen as the user writes or draws, your app can also track and collect the varying amounts of pressure used throughout a stroke. This information, along with settings for pen tip shape, size, and rotation, ink color, and purpose (plain ink, erasing, highlighting, and selecting), enables you to provide user experiences that closely resemble writing or drawing on paper with a pen, pencil, or brush.

> **Note**
>
> Your app can also support ink input from other pointer-based devices, including touch digitizers and mouse devices.

The ink platform is very flexible. It is designed to support various levels of functionality, depending on your requirements.

For Windows Ink UX guidelines, see Inking controls.

Components of the Windows Ink platform

Component	Description
InkCanvas	A XAML UI platform control that, by default, receives and displays all input from a pen as either an ink stroke or an erase stroke. For more information about how to use the InkCanvas, see Recognize Windows Ink strokes as text and Store and retrieve Windows Ink stroke data.
InkPresenter	A code-behind object, instantiated along with an **InkCanvas** control (exposed through the **InkCanvas.InkPresenter** property). This object provides all default inking functionality exposed by the **InkCanvas**, along with a comprehensive set of APIs for additional customization and personalization. For more information about how to use the InkPresenter, see Recognize Windows Ink strokes as text and Store and retrieve Windows Ink stroke data.
InkToolbar	A XAML UI platform control containing a customizable and extensible collection of buttons that activate ink-related features in an associated **InkCanvas**. For more information about how to use the InkToolbar, see Add an InkToolbar to a Windows app inking app.
IInkD2DRenderer	Enables the rendering of ink strokes onto the designated Direct2D device context of a Universal Windows app, instead of the default **InkCanvas** control. This enables full customization of the inking experience. For more information, see the Complex ink sample.

Basic inking with InkCanvas

To add basic inking functionality, just place an **InkCanvas** UWP platform control on the appropriate page in your app.

By default, the **InkCanvas** supports ink input only from a pen. The input is either rendered as an ink stroke using default settings for color and thickness (a black ballpoint pen with a thickness of 2 pixels), or treated as a stroke eraser (when input is from an eraser tip or the pen tip modified with an erase button).

> **Note**
>
> If an eraser tip or button is not present, the InkCanvas can be configured to process input from the pen tip as an erase stroke.

In this example, an **InkCanvas** overlays a background image.

> **Note**
>
> An InkCanvas has default **Height** and **Width** properties of zero, unless it is the child of an element that automatically sizes its child elements, such as **StackPanel** or **Grid** controls.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel x:Name="HeaderPanel" Orientation="Horizontal" Grid.Row="0">
        <TextBlock x:Name="Header"
                   Text="Basic ink sample"
                   Style="{ThemeResource HeaderTextBlockStyle}"
                   Margin="10,0,0,0" />
    </StackPanel>
    <Grid Grid.Row="1">
        <Image Source="Assets\StoreLogo.png" />
        <InkCanvas x:Name="inkCanvas" />
    </Grid>
</Grid>
```

This series of images shows how pen input is rendered by this **InkCanvas** control.

The blank **InkCanvas** with a background image.	The **InkCanvas** with ink strokes.	The **InkCanvas** with one stroke erased (note how erase operates on an entire stroke, not a portion).

The inking functionality supported by the **InkCanvas** control is provided by a code-behind object called the **InkPresenter**.

For basic inking, you don't have to concern yourself with the **InkPresenter**. However, to customize and configure inking behavior on the **InkCanvas**, you must access its corresponding **InkPresenter** object.

Basic customization with InkPresenter

An **InkPresenter** object is instantiated with each **InkCanvas** control.

> **Note**
>
> The **InkPresenter** cannot be instantiated directly. Instead, it is accessed through the **InkPresenter** property of the **InkCanvas**.

Along with providing all default inking behaviors of its corresponding **InkCanvas** control, the **InkPresenter** provides a comprehensive set of APIs for additional stroke customization and finer-grained management of the pen input (standard and modified). This includes stroke properties, supported input device types, and whether input is processed by the object or passed to the app for processing.

> **Note**
>
> Standard ink input (from either pen tip or eraser tip/button) is not modified with a secondary hardware affordance, such as a pen barrel button, right mouse button, or similar mechanism.

By default, ink is supported for pen input only. Here, we configure the **InkPresenter** to interpret input data from both pen and mouse as ink strokes. We also set some initial ink stroke attributes used for rendering strokes to the **InkCanvas**.

To enable mouse and touch inking, set the **InputDeviceTypes** property of the **InkPresenter** to the combination of **CoreInputDeviceTypes** values that you want.

C#

```
public MainPage()
{
    this.InitializeComponent();

    // Set supported inking device types.
    inkCanvas.InkPresenter.InputDeviceTypes =
        Windows.UI.Core.CoreInputDeviceTypes.Mouse |
        Windows.UI.Core.CoreInputDeviceTypes.Pen;

    // Set initial ink stroke attributes.
    InkDrawingAttributes drawingAttributes = new InkDrawingAttributes();
    drawingAttributes.Color = Windows.UI.Colors.Black;
    drawingAttributes.IgnorePressure = false;
    drawingAttributes.FitToCurve = true;

inkCanvas.InkPresenter.UpdateDefaultDrawingAttributes(drawingAttributes);
}
```

Ink stroke attributes can be set dynamically to accommodate user preferences or app requirements.

Here, we let a user choose from a list of ink colors.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel x:Name="HeaderPanel" Orientation="Horizontal" Grid.Row="0">
        <TextBlock x:Name="Header"
                   Text="Basic ink customization sample"
                   VerticalAlignment="Center"
                   Style="{ThemeResource HeaderTextBlockStyle}"
                   Margin="10,0,0,0" />
        <TextBlock Text="Color:"
                   Style="{StaticResource SubheaderTextBlockStyle}"
                   VerticalAlignment="Center"
                   Margin="50,0,10,0"/>
        <ComboBox x:Name="PenColor"
                  VerticalAlignment="Center"
```

```
                    SelectedIndex="0"
                    SelectionChanged="OnPenColorChanged">
                <ComboBoxItem Content="Black"/>
                <ComboBoxItem Content="Red"/>
            </ComboBox>
        </StackPanel>
        <Grid Grid.Row="1">
            <Image Source="Assets\StoreLogo.png" />
            <InkCanvas x:Name="inkCanvas" />
        </Grid>
    </Grid>
```

We then handle changes to the selected color and update the ink stroke attributes accordingly.

C#

```
// Update ink stroke color for new strokes.
private void OnPenColorChanged(object sender, SelectionChangedEventArgs e)
{
    if (inkCanvas != null)
    {
        InkDrawingAttributes drawingAttributes =
            inkCanvas.InkPresenter.CopyDefaultDrawingAttributes();

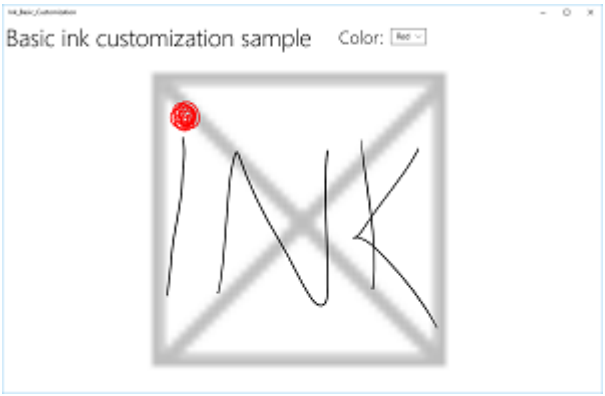
        string value =
((ComboBoxItem)PenColor.SelectedItem).Content.ToString();

        switch (value)
        {
            case "Black":
                drawingAttributes.Color = Windows.UI.Colors.Black;
                break;
            case "Red":
                drawingAttributes.Color = Windows.UI.Colors.Red;
                break;
            default:
                drawingAttributes.Color = Windows.UI.Colors.Black;
                break;
        };

inkCanvas.InkPresenter.UpdateDefaultDrawingAttributes(drawingAttributes);
    }
}
```

These images shows how pen input is processed and customized by the **InkPresenter**.

The InkCanvas with default black ink strokes.



The InkCanvas with user selected red ink strokes.

To provide functionality beyond inking and erasing, such as stroke selection, your app must identify specific input for the InkPresenter to pass through unprocessed for handling by your app.

Pass-through input for advanced processing

By default, InkPresenter processes all input as either an ink stroke or an erase stroke, including input modified by a secondary hardware affordance such as a pen barrel button, a right mouse button, or similar. However, users typically expect some additional functionality or modified behavior with these secondary affordances.

In some cases, you might also need to expose additional functionality for pens without secondary affordances (functionality not usually associated with the pen tip), other input device types, or some type of modified behavior based on a user selection in your app's UI.

To support this, InkPresenter can be configured to leave specific input unprocessed. This unprocessed input is then passed through to your app for processing.

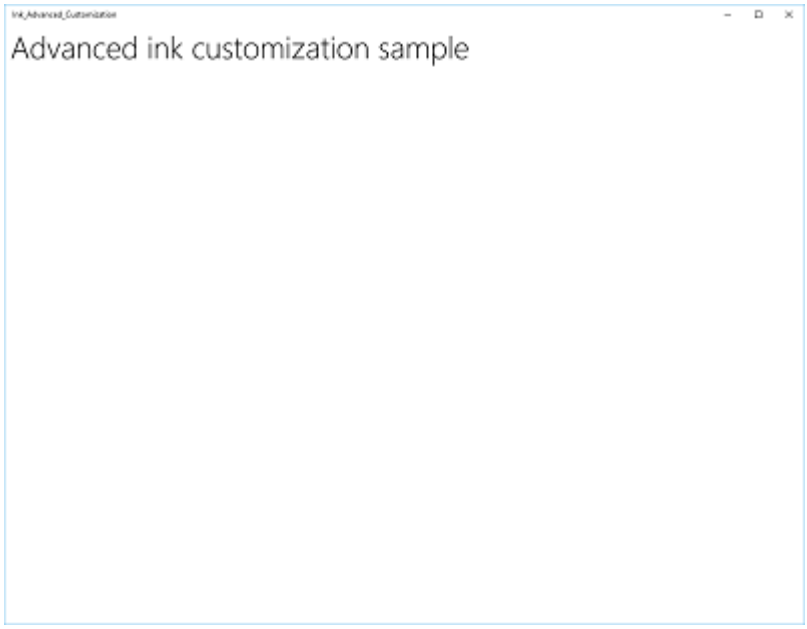
Example - Use unprocessed input to implement stroke selection

The Windows Ink platform does not provide built-in support for actions that require modified input, such as stroke selection. To support features like this, you must provide a custom solution in your apps.

The following code example (all code is in the MainPage.xaml and MainPage.xaml.cs files) steps through how to enable stroke selection when input is modified with a pen barrel button (or right mouse button).

1. First, we set up the UI in MainPage.xaml.

   Here, we add a canvas (below the **InkCanvas**) to draw the selection stroke. Using a separate layer to draw the selection stroke leaves the **InkCanvas** and its content untouched.



XAML

```
  <Grid Background="{ThemeResource
ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
      <RowDefinition Height="Auto"/>
      <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel x:Name="HeaderPanel" Orientation="Horizontal"
Grid.Row="0">
      <TextBlock x:Name="Header"
        Text="Advanced ink customization sample"
        VerticalAlignment="Center"
        Style="{ThemeResource HeaderTextBlockStyle}"
        Margin="10,0,0,0" />
    </StackPanel>
```

```
    <Grid Grid.Row="1">
      <!-- Canvas for displaying selection UI. -->
      <Canvas x:Name="selectionCanvas"/>
      <!-- Inking area -->
      <InkCanvas x:Name="inkCanvas"/>
    </Grid>
  </Grid>
```

2. In MainPage.xaml.cs, we declare a couple of global variables for keeping references to aspects of the selection UI. Specifically, the selection lasso stroke and the bounding rectangle that highlights the selected strokes.

```
C#
```

```
// Stroke selection tool.
private Polyline lasso;
// Stroke selection area.
private Rect boundingRect;
```

3. Next, we configure the **InkPresenter** to interpret input data from both pen and mouse as ink strokes, and set some initial ink stroke attributes used for rendering strokes to the **InkCanvas**.

   Most importantly, we use the **InputProcessingConfiguration** property of the InkPresenter to indicate that any modified input should be processed by the app. Modified input is specified by assigning **InputProcessingConfiguration.RightDragAction** a value of **InkInputRightDragAction.LeaveUnprocessed**. When this value is set, the InkPresenter passes through to the InkUnprocessedInput class, a set of pointer events for you to handle.

   We assign listeners for the unprocessed **PointerPressed**, **PointerMoved**, and **PointerReleased** events passed through by the **InkPresenter**. All selection functionality is implemented in the handlers for these events.

   Finally, we assign listeners for the **StrokeStarted** and **StrokesErased** events of the **InkPresenter**. We use the handlers for these events to clean up the selection UI if a new stroke is started or an existing stroke is erased.

C#

```
  public MainPage()
  {
    this.InitializeComponent();

    // Set supported inking device types.
    inkCanvas.InkPresenter.InputDeviceTypes =
      Windows.UI.Core.CoreInputDeviceTypes.Mouse |
      Windows.UI.Core.CoreInputDeviceTypes.Pen;

    // Set initial ink stroke attributes.
    InkDrawingAttributes drawingAttributes = new
InkDrawingAttributes();
    drawingAttributes.Color = Windows.UI.Colors.Black;
    drawingAttributes.IgnorePressure = false;
    drawingAttributes.FitToCurve = true;

inkCanvas.InkPresenter.UpdateDefaultDrawingAttributes(drawingAttributes
);

    // By default, the InkPresenter processes input modified by
    // a secondary affordance (pen barrel button, right mouse
    // button, or similar) as ink.
    // To pass through modified input to the app for custom processing
    // on the app UI thread instead of the background ink thread, set
    // InputProcessingConfiguration.RightDragAction to
LeaveUnprocessed.
    inkCanvas.InkPresenter.InputProcessingConfiguration.RightDragAction
=
        InkInputRightDragAction.LeaveUnprocessed;

    // Listen for unprocessed pointer events from modified input.
    // The input is used to provide selection functionality.
    inkCanvas.InkPresenter.UnprocessedInput.PointerPressed +=
        UnprocessedInput_PointerPressed;
    inkCanvas.InkPresenter.UnprocessedInput.PointerMoved +=
```

```
        UnprocessedInput_PointerMoved;
    inkCanvas.InkPresenter.UnprocessedInput.PointerReleased +=
        UnprocessedInput_PointerReleased;

    // Listen for new ink or erase strokes to clean up selection UI.
    inkCanvas.InkPresenter.StrokeInput.StrokeStarted +=
        StrokeInput_StrokeStarted;
    inkCanvas.InkPresenter.StrokesErased +=
        InkPresenter_StrokesErased;
}
```

4. We then define handlers for the unprocessed **PointerPressed**, **PointerMoved**, and **PointerReleased** events passed through by the **InkPresenter**.

   All selection functionality is implemented in these handlers, including the lasso stroke and the bounding rectangle.

C#

```
// Handle unprocessed pointer events from modified input.
// The input is used to provide selection functionality.
// Selection UI is drawn on a canvas under the InkCanvas.
private void UnprocessedInput_PointerPressed(
    InkUnprocessedInput sender, PointerEventArgs args)
{
    // Initialize a selection lasso.
    lasso = new Polyline()
    {
        Stroke = new SolidColorBrush(Windows.UI.Colors.Blue),
        StrokeThickness = 1,
        StrokeDashArray = new DoubleCollection() { 5, 2 },
        };

        lasso.Points.Add(args.CurrentPoint.RawPosition);
```

```
            selectionCanvas.Children.Add(lasso);
        }

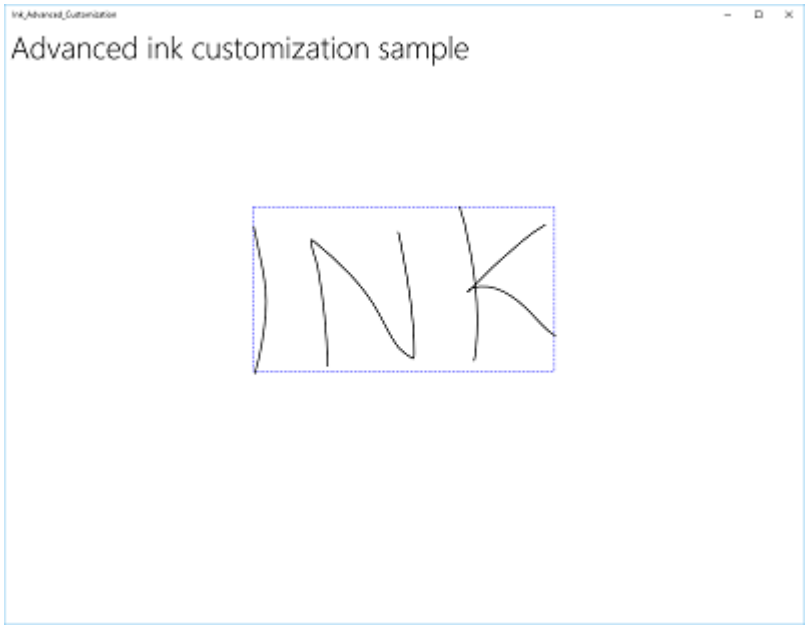
        private void UnprocessedInput_PointerMoved(
          InkUnprocessedInput sender, PointerEventArgs args)
        {
          // Add a point to the lasso Polyline object.
          lasso.Points.Add(args.CurrentPoint.RawPosition);
        }

        private void UnprocessedInput_PointerReleased(
          InkUnprocessedInput sender, PointerEventArgs args)
        {
          // Add the final point to the Polyline object and
          // select strokes within the lasso area.
          // Draw a bounding box on the selection canvas
          // around the selected ink strokes.
          lasso.Points.Add(args.CurrentPoint.RawPosition);

          boundingRect =
            inkCanvas.InkPresenter.StrokeContainer.SelectWithPolyLine(
              lasso.Points);

          DrawBoundingRect();
        }
```

5. To conclude the PointerReleased event handler, we clear the selection layer of all content (the lasso stroke) and then draw a single bounding rectangle around the ink strokes encompassed by the lasso area.



C#

```
// Draw a bounding rectangle, on the selection canvas, encompassing
// all ink strokes within the lasso area.
private void DrawBoundingRect()
```

```
{
  // Clear all existing content from the selection canvas.
  selectionCanvas.Children.Clear();

  // Draw a bounding rectangle only if there are ink strokes
  // within the lasso area.
  if (!((boundingRect.Width == 0) ||
    (boundingRect.Height == 0) ||
    boundingRect.IsEmpty))
    {
      var rectangle = new Rectangle()
      {
        Stroke = new SolidColorBrush(Windows.UI.Colors.Blue),
          StrokeThickness = 1,
          StrokeDashArray = new DoubleCollection() { 5, 2 },
          Width = boundingRect.Width,
          Height = boundingRect.Height
      };

      Canvas.SetLeft(rectangle, boundingRect.X);
      Canvas.SetTop(rectangle, boundingRect.Y);

      selectionCanvas.Children.Add(rectangle);
    }
  }
```

6. Finally, we define handlers for the StrokeStarted and StrokesErased InkPresenter events.

   These both just call the same cleanup function to clear the current selection whenever a new stroke is detected.

```
C#

  // Handle new ink or erase strokes to clean up selection UI.
  private void StrokeInput_StrokeStarted(
    InkStrokeInput sender, Windows.UI.Core.PointerEventArgs args)
  {
    ClearSelection();
  }

  private void InkPresenter_StrokesErased(
    InkPresenter sender, InkStrokesErasedEventArgs args)
  {
    ClearSelection();
  }
```

7. Here's the function to remove all selection UI from the selection canvas when a new stroke is started or an existing stroke is erased.

C#

```
// Clean up selection UI.
private void ClearSelection()
{
  var strokes = inkCanvas.InkPresenter.StrokeContainer.GetStrokes();
  foreach (var stroke in strokes)
  {
    stroke.Selected = false;
  }
  ClearDrawnBoundingRect();
 }

private void ClearDrawnBoundingRect()
{
  if (selectionCanvas.Children.Any())
  {
    selectionCanvas.Children.Clear();
    boundingRect = Rect.Empty;
  }
}
```

Custom ink rendering

By default, ink input is processed on a low-latency background thread and rendered in-progress, or "wet", as it is drawn. When the stroke is completed (pen or finger lifted, or mouse button released), the stroke is processed on the UI thread and rendered "dry" to the **InkCanvas** layer (above the application content and replacing the wet ink).

You can override this default behavior and completely control the inking experience by "custom drying" the wet ink strokes. While the default behavior is typically sufficient for most applications, there are a few cases where custom drying might be required, these include:

- More efficient management of large, or complex, collections of ink strokes
- More efficient panning and zooming support on large ink canvases
- Interleaving ink and other objects, such as shapes or text, while maintaining z-order
- Drying and converting ink synchronously into a DirectX shape (for example, a straight line or shape rasterized and integrated into application content instead of as a separate **InkCanvas** layer).

Custom drying requires an **IInkD2DRenderer** object to manage the ink input and render it to the Direct2D device context of your Universal Windows app, instead of the default **InkCanvas** control.

By calling **ActivateCustomDrying** (before the **InkCanvas** is loaded), an app creates an **InkSynchronizer** object to customize how an ink stroke is rendered dry to a **SurfaceImageSource** or **VirtualSurfaceImageSource**.

Both **SurfaceImageSource** and **VirtualSurfaceImageSource** provide a DirectX shared surface for your app to draw into and compose into your application's content, although VSIS provides a virtual surface that's larger than the screen for performant panning and zooming. Because visual updates to these surfaces are synchronized with the XAML UI thread, when ink is rendered to either, the wet ink can be removed from the InkCanvas simultaneously.

You can also custom dry ink to a SwapChainPanel, but synchronization with the UI thread is not guaranteed and there might be a delay between when the ink is rendered to your SwapChainPanel and when ink is removed from the InkCanvas.

For a full example of this functionality, see the Complex ink sample.

> **Note**
>
> Custom drying and the **InkToolbar**
> If your app overrides the default ink rendering behavior of the **InkPresenter** with a custom drying implementation, the rendered ink strokes are no longer available to the InkToolbar and the built-in erase commands of the InkToolbar do not work as expected. To provide erase functionality, you must handle all pointer events, perform hit-testing on each stroke, and override the built-in "Erase all ink" command.

Other articles in this section

Topic	Description
Recognize ink strokes	Convert ink strokes to text using handwriting recognition, or to shapes using custom recognition.
Store and retrieve ink strokes	Store ink stroke data in a Graphics Interchange Format (GIF) file using embedded Ink Serialized Format (ISF) metadata.
Add an InkToolbar to a Windows inking app	Add a default InkToolbar to a Windows app inking app, add a custom pen button to the InkToolbar, and bind the custom pen button to a custom pen definition.

Pen interactions and haptic (tactile) feedback

Article • 06/16/2022

Windows has long supported digital pens that let users interact with their devices in a natural, direct fashion and to express their creativity through rich writing and drawing experiences using digital ink.

With Windows 11, a new capability is being introduced that makes the digital pen experience even more natural and compelling: When using a pen that supports "haptic feedback", users can actually feel their pen interacting in a tactile manner with the user interface (UI) of an app.

> **Note**
>
> When referring to this new feature, "haptic" is used throughout the developer APIs and related documentation, while "tactile" is the friendly name presented to users for setting feedback preferences in Windows Settings.

Haptic feedback experiences supported in Windows 11 include *inking feedback* and *interaction feedback*:

- Inking feedback simulates the feel of various types of writing or drawing tools (such as pen, marker, pencil, highlighter, and so on) through continuous vibrations while the pen is in contact with the screen. By default, the Windows Ink Platform supports haptic feedback for all drawing tools (this topic covers how to provide a custom inking solution beyond the one supported by Windows Ink).
- Interaction feedback, on the other hand, is direct feedback based on key user actions such as hovering over or clicking a button, responding to the completion of an action, or to draw the user's attention.

Typically, five steps are required to fully support haptic feedback:

- Detect pen input.
- Determine if the current pen and device support haptic feedback and, if so, what haptic feedback features it supports.
- Decide on the haptic feedback signal to send.
- Send the haptic feedback.
- Stop the haptic feedback

Detect pen input

To detect and isolate pen input, you must first register for the PointerEntered event and then check whether the PointerDeviceType is a pen.

The following code shows how to check the pointer device type within a PointerEntered event. For this example, if the input is not from a pen we simply return from the event handler. Otherwise, we check the pen capabilities and configure the haptic feedback.

C#

```
private void InputObserver_PointerEntered(object sender,
PointerRoutedEventArgs e)
{
    ...

    // If the current Pointer device is not a pen, exit.
    if (e.Pointer.PointerDeviceType != PointerDeviceType.Pen)
    {
       return;
    }

    ...
}
```

Determine support for haptic feedback

Not all pens and digitizers support haptic feedback, and the pens that do won't necessarily support all haptic feedback features described in this topic. As such, it is important to programmatically confirm which features are supported by the active pen.

In a continuation of the preceding example, we show how to check whether the active pen supports haptic feedback.

We first attempt to retrieve a PenDevice object from the current PointerId. If a PenDevice cannot be obtained, we simply return from the event handler.

If a PenDevice was obtained, we test if it supports a SimpleHapticsController property. If not, we again simply return from the event handler.

C#

```
// Attempt to retrieve the PenDevice from the current PointerId.
penDevice = PenDevice.GetFromPointerId(e.Pointer.PointerId);
```

```
// If a PenDevice cannot be retrieved based on the PointerId, it does not su
pport
// advanced pen features, such as haptic feedback.
if (penDevice == null)
{
    return;
}

// Check to see if the current PenDevice supports haptic
feedback by seeing if it
// has a SimpleHapticsController.
hapticsController = penDevice.SimpleHapticsController;
if (hapticsController == null)
{
    return;
}
```

The SimpleHapticsController retrieved in the preceding example is used in subsequent examples to query haptic capabilities and to send/stop haptic feedback.

> **Note**
>
> If you are building apps with the **Windows App SDK Preview 1.0**, you can use **PenDevice interop** (**PenDeviceInterop.FromPointerPoint(PointerPoint)**) to access the system **PenDevice**.

C#

```
private void InputObserver_PointerEntered(PointerInputObserver sender,
PointerEventArgs args)
{
    var penDevice =
PenDeviceInterop.PenDeviceFromPointerPoint(args.CurrentPoint);
}
```

The following sections describe the feedback features that haptic pens must support, as well as those that are optional. A required haptic feedback type can typically be used as a fallback instead of an optional feature.

Inking waveforms

Inking waveforms play continuously while the pen is in contact with the screen, and attempt to simulate the feel of various writing or drawing tools.

Feature	Description	Required / Optional
InkContinous waveform	Simulates the feel of inking with a physical ball point pen. This is the default fallback when an inking waveform is not supported by a haptic pen.	Required
BrushContinuous waveform	Continuous haptic signal when user selects brush as inking tool.	Optional
ChiselMarkerContinuous waveform	Continuous haptic signal when user selects chisel marker/highlighter as inking tool.	Optional
EraserContinuous waveform	Continuous haptic signal when user selects eraser as inking tool.	Optional
GalaxyContinuous waveform (the HID documentation and implementation guide refers to this waveform as *SparkleContinuous*)	Continuous haptic signal for special ink tools, such as a multi-colored brush.	Optional
MarkerContinuous waveform	Continuous haptic signal when user selects marker as inking tool.	Optional
PencilContinuous waveform	Continuous haptic signal when user selects pencil as inking tool.	Optional

Interaction waveforms

Interaction waveforms are typically short (exceptions noted in the following table), direct feedback waveforms generated on demand to confirm key actions such as hovering over or clicking a button, responding to the completion of an action, or to draw the user's attention.

Feature	Description	Required / Optional
Click waveform	A short "click" feedback. This is the default fallback when an interaction waveform selected by the app is not supported by a haptic pen.	Required
Error waveform	A strong signal to alert the user that an action failed, or an error has occurred.	Optional

Feature	Description	Required / Optional
Hover waveform	Indicates that the user has started hovering over an interactive UI element.	Optional
Press waveform	Indicates when a user presses an interactive UI element in an incremental action (see Release).	Optional
Release waveform	Indicates when a user releases an interactive UI element in an incremental action (see Press).	Optional
Success waveform	Strong signal to alert the user that an action succeeded.	Optional
BuzzContinuous waveform	Continuous buzzing sensation.	Optional
RumbleContinuous waveform	Continuous rumbling sensation.	Optional

Haptic feedback customizations

Some haptic pens can support the following customizations.

Feature	Description	Required / Optional
Intensity	Sets the intensity of the haptic signal.	Optional
Play Count	Repeats a haptic signal a specified number of times.	Optional
Replay Pause Interval	Sets the time between each repeated playing of the haptic signal.	Optional
Play Duration	Sets the interval of time that a haptic signal is played.	Optional

Check for custom settings support

To check for Intensity, Play Count, Replay Pause Interval, and Play Duration support, use the following properties of the SimpleHapticsController:

- IsIntensitySupported
- IsPlayCountSupported
- IsPlayDurationSupported
- IsReplayPauseIntervalSupported

Send and stop inking haptic feedback

Use the SendHapticFeedback method of the SimpleHapticsController object to pass inking waveforms to the user's pen. This method supports passing in either a waveform or both a waveform with a customized intensity value (see Customize haptic feedback).

Call SendHapticFeedback and pass in an inking waveform to configure the pen to start playing that waveform as soon as the tip of the pen touches anywhere on the screen. The waveform will continue playing until the pen is lifted or StopFeedback is called, whichever happens first. We recommend doing this in the PointerEntered event handler for the element in which you want haptics to be played. For example, an app with a custom inking implementation would do this in the PointerEntered method of its inking canvas.

To retrieve the desired inking waveform, you must iterate through the SupportedFeedback collection of the SimpleHapticsController, ensuring it is supported by the active pen.

If it is not supported, you can either choose to not play anything at all or fall back to the InkContinuous waveform, as that is guaranteed to be supported.

In the following example, we attempt to send the BrushContinuous waveform (but fall back to InkContinuous if BrushContinuous is not supported).

C#

```
SimpleHapticsControllerFeedback currentWaveform;

// Attempt to set the currentWaveform to BrushContinuous.
foreach (var waveform in hapticsController.SupportedFeedback)
{
    if (waveform.Waveform == KnownSimpleHapticsControllerWaveforms.BrushCont
inuous)
    {
        currentWaveform = waveform;
    }
}

// If currentWaveform is null, it was not in the SupportedFeedback collectio
n, so instead set
// the waveform to InkContinuous.
if (currentWaveform == null)
{
    foreach (var waveform in hapticsController.SupportedFeedback)
    {
        if (waveform.Waveform == KnownSimpleHapticsControllerWaveforms.InkCo
ntinuous)
        {
```

```
            currentWaveform = waveform;
        }
    }
}

// Send the currentWaveform
hapticsController.SendHapticFeedback(currentWaveform);
```

It is important that you also stop haptic feedback when the associated pointer exits the element you registered for haptic feedback. Otherwise, the waveform will continue attempting to play on the active pen.

> **Note**
>
> Some pens may optionally stop haptics on their own when the pen leaves the range of the screen. However, it is not required for all pens to do this, so applications should always explicitly stop haptic feedback as described here.

To stop haptic feedback on an element, register for the PointerExited event on same element as you registered the PointerEntered handler that sent the haptic signal. In that exited event handler, call StopFeedback as shown here.

C#

```
hapticsController.StopFeedback();
```

Send and stop interaction feedback

Sending Interaction feedback is quite similar to sending inking feedback.

Use the SendHapticFeedback method of the SimpleHapticsController object to pass interaction waveforms to the user's pen. This method supports passing in either a waveform or both a waveform with a customized intensity value (see Customize haptic feedback).

Call SendHapticFeedback and pass in an inking waveform to configure the pen to start playing that waveform immediately based on some interaction within your app (instead of when the tip of the pen touches the screen for inking feedback).

When using any of the non-continuous Interaction waveforms, it is not necessary to make a corresponding StopFeedback call. You do still need to call StopFeedback for the continuous Interaction waveforms.

> **Note**
>
> Sending an interaction waveform when an inking waveform is being played will temporarily interrupt the inking waveform. The inking waveform will resume when the interaction waveform stops.

To retrieve the desired interaction waveform, you must iterate through the SupportedFeedback collection of the SimpleHapticsController, ensuring it is supported by the active pen.

If it is not supported, you can either choose to not play anything at all or fall back to the Click waveform, as that is guaranteed to be supported.

In the following example, we attempt to send the Error waveform (but fall back to Click if Error is not supported).

C#

```
SimpleHapticsControllerFeedback currentWaveform;

// Attempt to set the currentWaveform to BrushContinuous.
foreach (var waveform in hapticsController.SupportedFeedback)
{
    if (waveform.Waveform == KnownSimpleHapticsControllerWaveforms.Error)
    {
        currentWaveform = waveform;
    }
}

// If currentWaveform is null, it was not in the SupportedFeedback collectio
n, so instead set
// the waveform to Click.
if (currentWaveform == null)
{
    foreach (var waveform in hapticsController.SupportedFeedback)
    {
        if (waveform.Waveform == KnownSimpleHapticsControllerWaveforms.Click
)
        {
            currentWaveform = waveform;
        }
    }
}

// Send the currentWaveform.
hapticsController.SendHapticFeedback(currentWaveform);
```

Customize haptic feedback

There are three ways to customize haptic feedback. The first is supported by both Inking and Interaction feedback, while the second and third are only supported by Interaction feedback.

1. Adjust the intensity of the feedback relative to the maximum system intensity setting. To do this, you must first check to ensure that the SimpleHapticsController supports setting the intensity and then call SendHapticFeedback with the desired `Intensity` value.

```
C#
```

```
if (hapticsController.IsIntensitySupported)
{
    foreach (var waveform in hapticsController.SupportedFeedback)
    {
        if (waveform.Waveform == KnownSimpleHapticsControllerWaveforms.
Click)
        {
            double intensity = 0.75;
            hapticsController.SendHapticFeedback(waveform, intensity);
        }
    }
}
```

2. Repeat the haptic signal a specified number of times. To do this, you must first check to ensure that the SimpleHapticsController supports setting the intensity and then call SendHapticFeedbackForPlayCount with the desired count value. You can also set both the intensity and the replay pause interval.

> **Note**
>
> If the SimpleHapticsController does not support setting the intensity or the replay pause interval, the supplied values will be ignored.

```
C#
```

```
if (hapticsController.IsPlayCountSupported && hapticsController.IsInten
sitySupported && hapticsController.IsReplayPauseIntervalSupported)
{
    foreach (var waveform in hapticsController.SupportedFeedback)
    {
        if (waveform.Waveform == KnownSimpleHapticsControllerWaveforms.
Click)
        {
```

```
            double intensity = 0.75;
            int playCount = 3;
            System.TimeSpan pauseDuration = new System.TimeSpan(1000000
);
            hapticsController.SendHapticFeedbackForPlayCount(currentWav
eform, intensity, playCount, pauseDuration);
        }
    }
}
```

3. Set the duration of the haptic signal. To do this, you must first check to ensure that the SimpleHapticsController supports setting the play duration and then call SendHapticFeedbackForDuration with the desired time interval value. You can also set the intensity.

> **Note**
>
> If the SimpleHapticsController does not support setting the intensity, the supplied value will be ignored.

C#

```
if (hapticsController.IsPlayDurationSupported && hapticsController.IsIn
tensitySupported)
{
    foreach (var waveform in hapticsController.SupportedFeedback)
    {
        if (waveform.Waveform == KnownSimpleHapticsControllerWaveforms.
RumbleContinuous)
        {
            double intensity = 0.75;
            System.TimeSpan playDuration = new System.TimeSpan(5000000)
;
            hapticsController.SendHapticFeedbackForDuration(currentWave
form, intensity, playDuration);
        }
    }
}
```

Examples

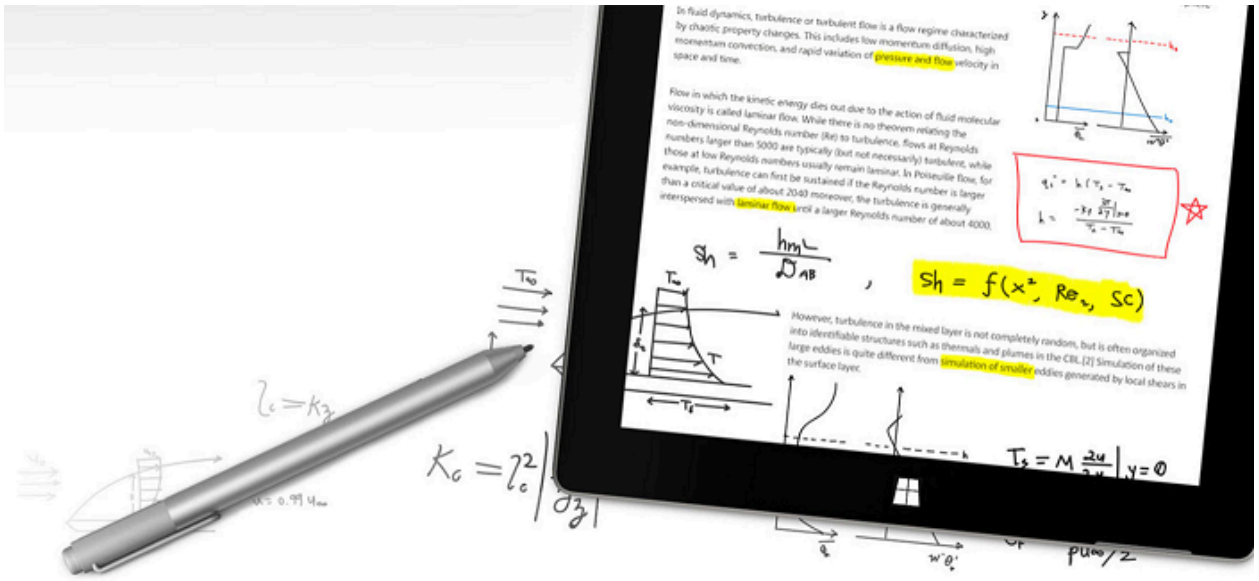
See the Pen haptics sample for working examples of the following functionality:

- Get a SimpleHapticsController from pen input: Go from PointerId to PenDevice to SimpleHapticsController (requires both a haptic-capable pen and a device that supports the pen).

- Check pen haptics capabilities: A SimpleHapticsController exposes properties for pen hardware capabilities, including IsIntensitySupported, IsPlayCountSupported, SupportedFeedback, and so on.
- Start and stop haptic feedback: Use the SendHapticFeedback and StopFeedback methods appropriately.
- Trigger haptic feedback: Feedback for both *inking feedback* and *interaction feedback*.

Tutorial: Support ink in your Windows app

Article • 02/27/2025



Surface Pen (available for purchase at the Microsoft Store).

This tutorial steps through how to create a basic Windows app that supports writing and drawing with Windows Ink. We use snippets from a sample app, which you can download from GitHub (see Sample code), to demonstrate the various features and associated Windows Ink APIs (see Components of the Windows Ink platform) discussed in each step.

We focus on the following:

- Adding basic ink support
- Adding an ink toolbar
- Supporting handwriting recognition
- Supporting basic shape recognition
- Saving and loading ink

For more detail about implementing these features, see Pen interactions and Windows Ink in Windows apps.

Introduction

With Windows Ink, you can provide your customers with the digital equivalent of almost any pen-and-paper experience imaginable, from quick, handwritten notes and

annotations to whiteboard demos, and from architectural and engineering drawings to personal masterpieces.

Prerequisites

- A computer (or a virtual machine) running the current version of Windows 10 or Windows 11
- Visual Studio 2019 and the RS2 SDK or later
- Windows 10 SDK (10.0.15063.0)
- Depending on your configuration, you might have to install the Microsoft.NETCore.UniversalWindowsPlatform NuGet package and enable **Developer mode** in your system settings (Settings -> Update & Security -> For developers -> Use developer features).
- If you're new to Windows app development with Visual Studio, have a look through these topics before you start this tutorial:
  - Install tools for the Windows App SDK
  - Create a "Hello, world" app (XAML)
- **[OPTIONAL]** A digital pen and a computer with a display that supports input from that digital pen.

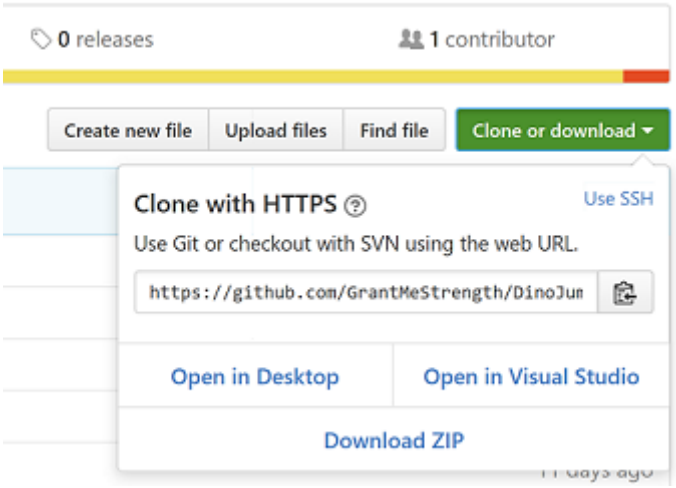
> **Note**
>
> While Windows Ink can support drawing with a mouse and touch (we show how to do this in Step 3 of this tutorial) for an optimal Windows Ink experience, we recommend that you have a digital pen and a computer with a display that supports input from that digital pen.

Sample code

Throughout this tutorial, we use a sample ink app to demonstrate the concepts and functionality discussed.

Download this Visual Studio sample and source code from GitHub at windows-appsample-get-started-ink sample:

1. Select the green **Clone or download** button



2. If you have a GitHub account, you can clone the repo to your local machine by choosing **Open in Visual Studio**
3. If you don't have a GitHub account, or you just want a local copy of the project, choose **Download ZIP** (you'll have to check back regularly to download the latest updates)

> **ⓘ Important**
>
> Most of the code in the sample is commented out. As we go through each step, you'll be asked to uncomment various sections of the code. In Visual Studio, just highlight the lines of code, and press CTRL-K and then CTRL-U.

Components of the Windows Ink platform

These objects provide the bulk of the inking experience for Windows apps.

Expand table

Component	Description
InkCanvas	A XAML UI platform control that, by default, receives and displays all input from a pen as either an ink stroke or an erase stroke.
InkPresenter	A code-behind object, instantiated along with an InkCanvas control (exposed through the InkCanvas.InkPresenter property). This object provides all default inking functionality exposed by the InkCanvas, along with a comprehensive set of APIs for additional customization and personalization.
InkToolbar	A XAML UI platform control containing a customizable and extensible collection of buttons that activate ink-related features

Component	Description
	in an associated **InkCanvas**.
IInkD2DRenderer We do not cover this functionality here, for more information, see the Complex ink sample.	Enables the rendering of ink strokes onto the designated Direct2D device context of a Universal Windows app, instead of the default **InkCanvas** control.

Step 1: Run the sample

After you've downloaded the RadialController sample app, verify that it runs:

1. Open the sample project in Visual Studio.
2. Set the **Solution Platforms** dropdown to a non-Arm selection.
3. Press F5 to compile, deploy, and run.

> **Note**
>
> Alternatively, you can select **Debug** > **Start debugging** menu item, or select the **Local Machine** Run button shown here.
>
> >

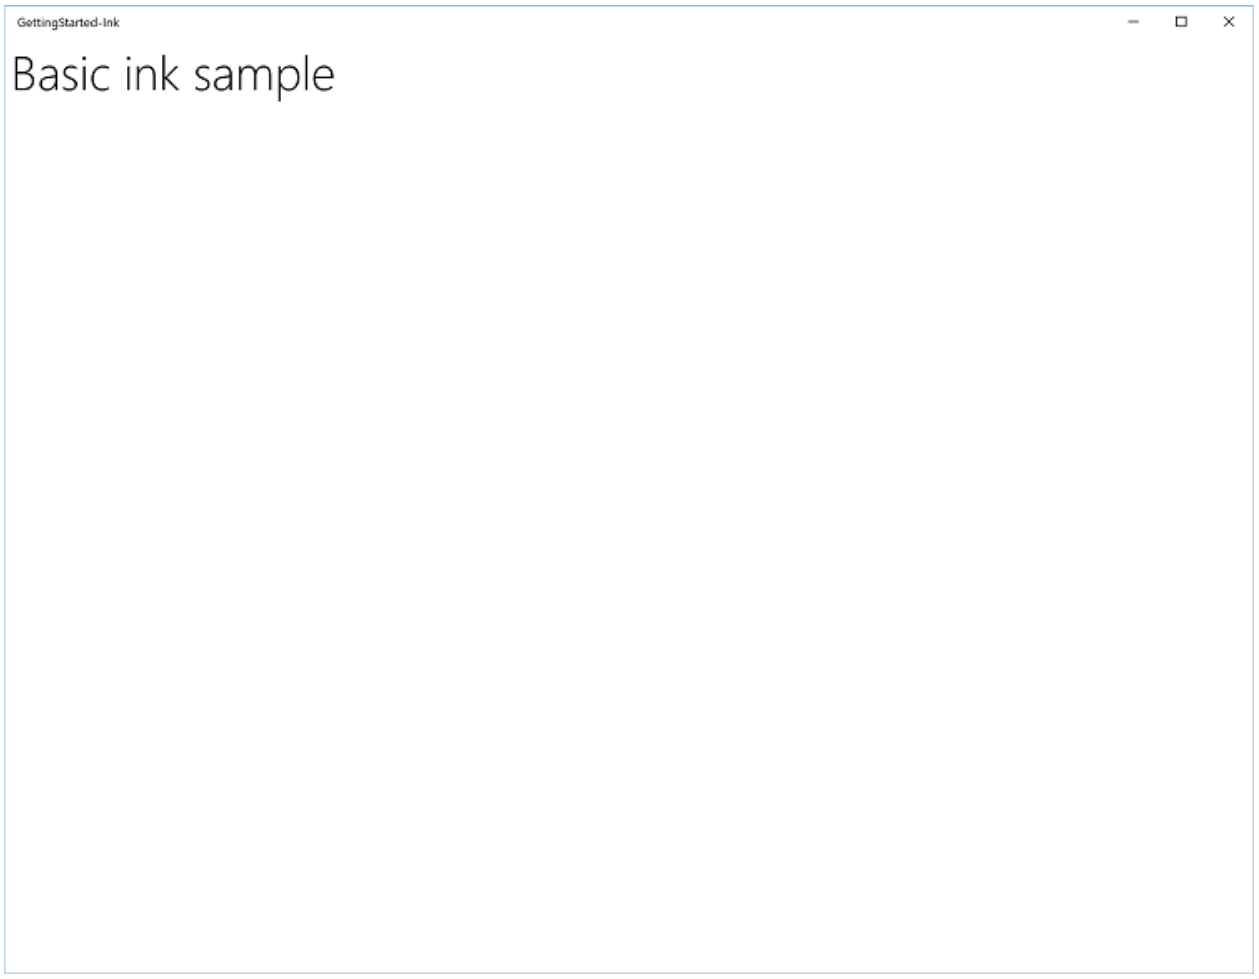
The app window opens, and after a splash screen appears for a few seconds, you'll see this initial screen.



Okay, we now have the basic Windows app that we'll use throughout the rest of this tutorial. In the following steps, we add our ink functionality.

Step 2: Use InkCanvas to support basic inking

Perhaps you've probably already noticed that the app, in it's initial form, doesn't let you draw anything with the pen (although you can use the pen as a standard pointer device to interact with the app).

Let's fix that little shortcoming in this step.

To add basic inking functionality, just place an **InkCanvas** control on the appropriate page in your app.

> ⓘ **Note**
>
> An InkCanvas has default **Height** and **Width** properties of zero, unless it is the child of an element that automatically sizes its child elements.

In the sample:

1. Open the MainPage.xaml.cs file.
2. Find the code marked with the title of this step ("// Step 2: Use InkCanvas to support basic inking").
3. Uncomment the following lines. (These references are required for the functionality used in the subsequent steps).

C#

```
using Windows.UI.Input.Inking;
using Windows.UI.Input.Inking.Analysis;
using Windows.UI.Xaml.Shapes;
using Windows.Storage.Streams;
```

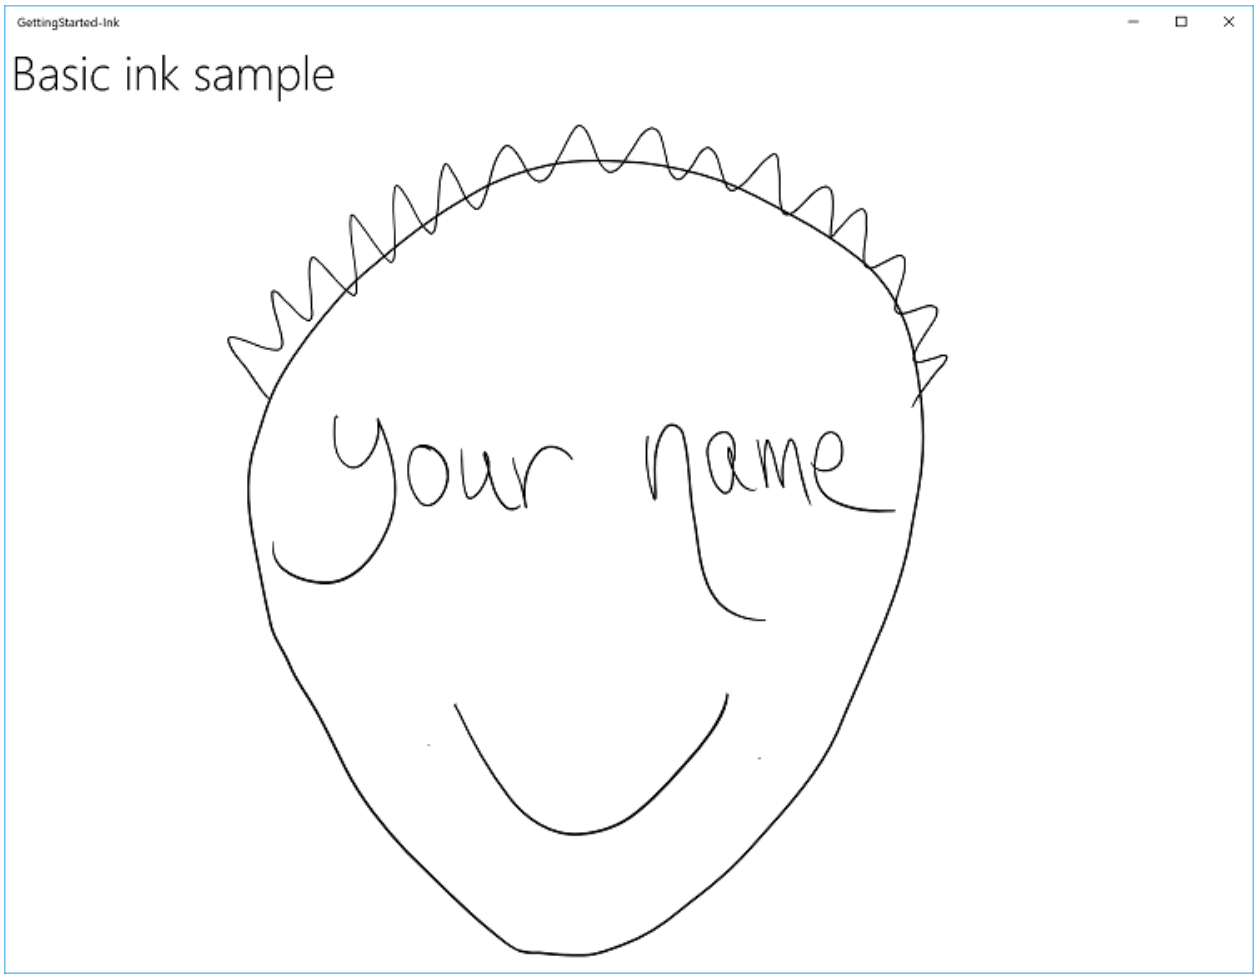
4. Open the MainPage.xaml file.
5. Find the code marked with the title of this step ("<!-- Step 2: Basic inking with InkCanvas -->").
6. Uncomment the following line.

XAML

```
<InkCanvas x:Name="inkCanvas" />
```

That's it!

Now run the app again. Go ahead and scribble, write your name, or (if you're holding a mirror or have a very good memory) draw your self-portrait.



Step 3: Support inking with touch and mouse

You'll notice that, by default, ink is supported for pen input only. If you try to write or draw with your finger, your mouse, or your touchpad, you'll be disappointed.

To turn that frown upside down , you need to add a second line of code. This time it's in the code-behind for the XAML file in which you declared your **InkCanvas**.

In this step, we introduce the **InkPresenter** object, which provides finer-grained management of the input, processing, and rendering of ink input (standard and modified) on your **InkCanvas**.

> ⓘ **Note**
>
> Standard ink input (pen tip or eraser tip/button) is not modified with a secondary hardware affordance, such as a pen barrel button, right mouse button, or similar mechanism.

To enable mouse and touch inking, set the **InputDeviceTypes** property of the **InkPresenter** to the combination of **CoreInputDeviceTypes** values that you want.

In the sample:

1. Open the MainPage.xaml.cs file.
2. Find the code marked with the title of this step ("// Step 3: Support inking with touch and mouse").
3. Uncomment the following lines.

```
C#
```

```
    inkCanvas.InkPresenter.InputDeviceTypes =
        Windows.UI.Core.CoreInputDeviceTypes.Mouse |
        Windows.UI.Core.CoreInputDeviceTypes.Touch |
        Windows.UI.Core.CoreInputDeviceTypes.Pen;
```

Run the app again and you'll find that all your finger-painting-on-a-computer-screen dreams have come true!

> **Note**
>
> When specifying input device types, you must indicate support for each specific input type (including pen), because setting this property overrides the default InkCanvas setting.

Step 4: Add an ink toolbar

The **InkToolbar** is a UWP platform control that provides a customizable and extensible collection of buttons for activating ink-related features.

By default, the **InkToolbar** includes a basic set of buttons that let users quickly select between a pen, a pencil, a highlighter, or an eraser, any of which can be used together with a stencil (ruler or protractor). The pen, pencil, and highlighter buttons each also provide a flyout for selecting ink color and stroke size.

To add a default **InkToolbar** to an inking app, just place it on the same page as your **InkCanvas** and associate the two controls.

In the sample

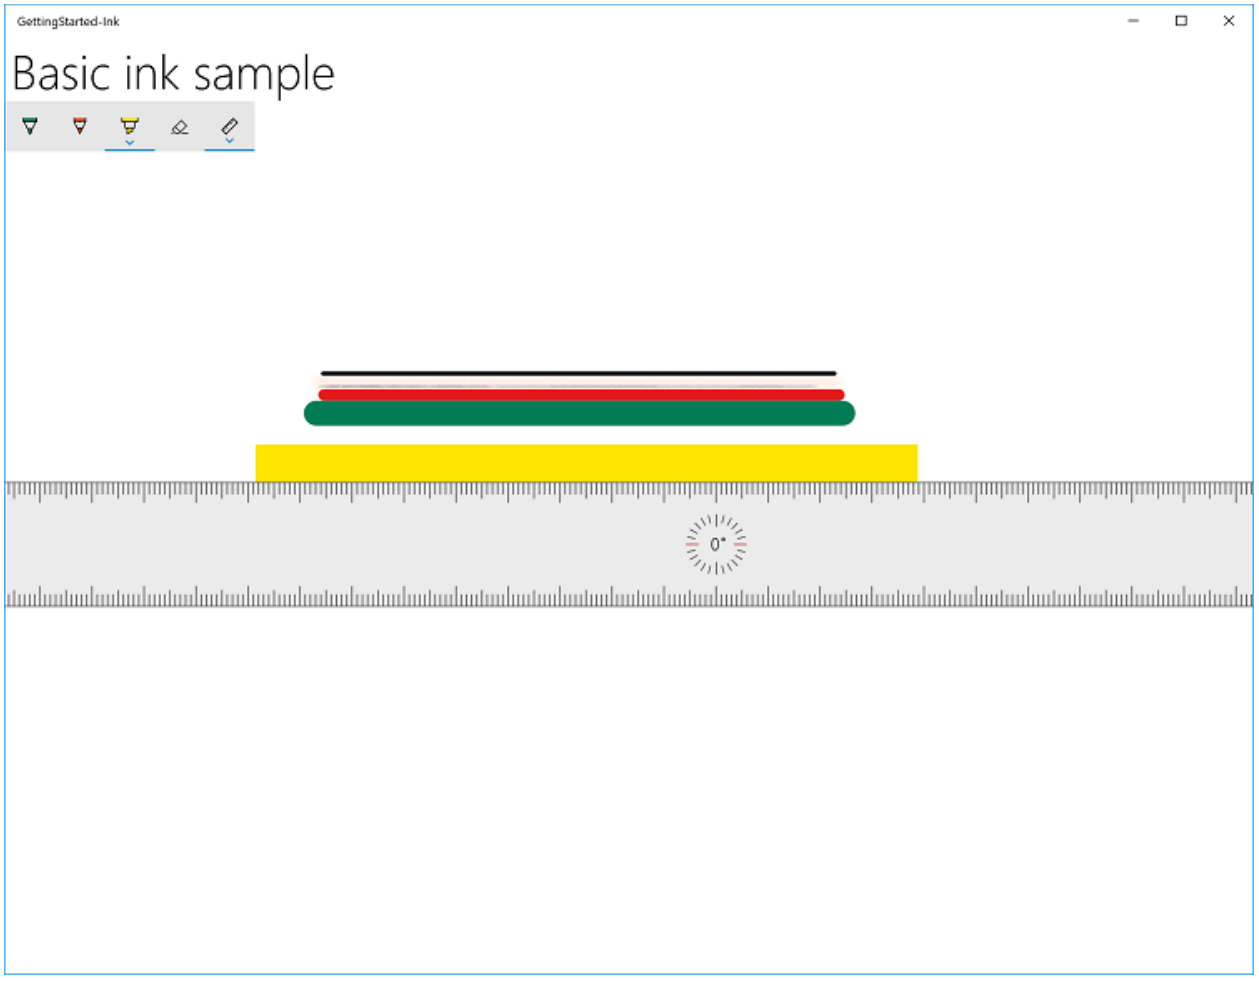
1. Open the MainPage.xaml file.
2. Find the code marked with the title of this step ("<!-- Step 4: Add an ink toolbar -->").
3. Uncomment the following lines.

XAML

```
    <InkToolbar x:Name="inkToolbar"
                        VerticalAlignment="Top"
                        Margin="10,0,10,0"
                        TargetInkCanvas="{x:Bind inkCanvas}">
    </InkToolbar>
```

> **Note**
>
> To keep the UI and code as uncluttered and simple as possible, we use a basic Grid layout and declare the InkToolbar after the InkCanvas in a grid row. If you declare it before the InkCanvas, the InkToolbar is rendered first, below the canvas and inaccessible to the user.

Now run the app again to see the **InkToolbar** and try out some of the tools.



Challenge: Add a custom button

Here's an example of a custom **InkToolbar** (from Sketchpad in the Windows Ink Workspace).

For more details about customizing an InkToolbar, see Add an InkToolbar to a Windows app inking app.

Step 5: Support handwriting recognition

Now that you can write and draw in your app, let's try to do something useful with those scribbles.

In this step, we use the handwriting recognition features of Windows Ink to try to decipher what you've written.

> **Note**
>
> Handwriting recognition can be improved through the **Pen & Windows Ink** settings:
>
> 1. Open the Start menu and select **Settings**.
> 2. From the Settings screen select **Devices** > **Pen & Windows Ink**.
>
> >
>
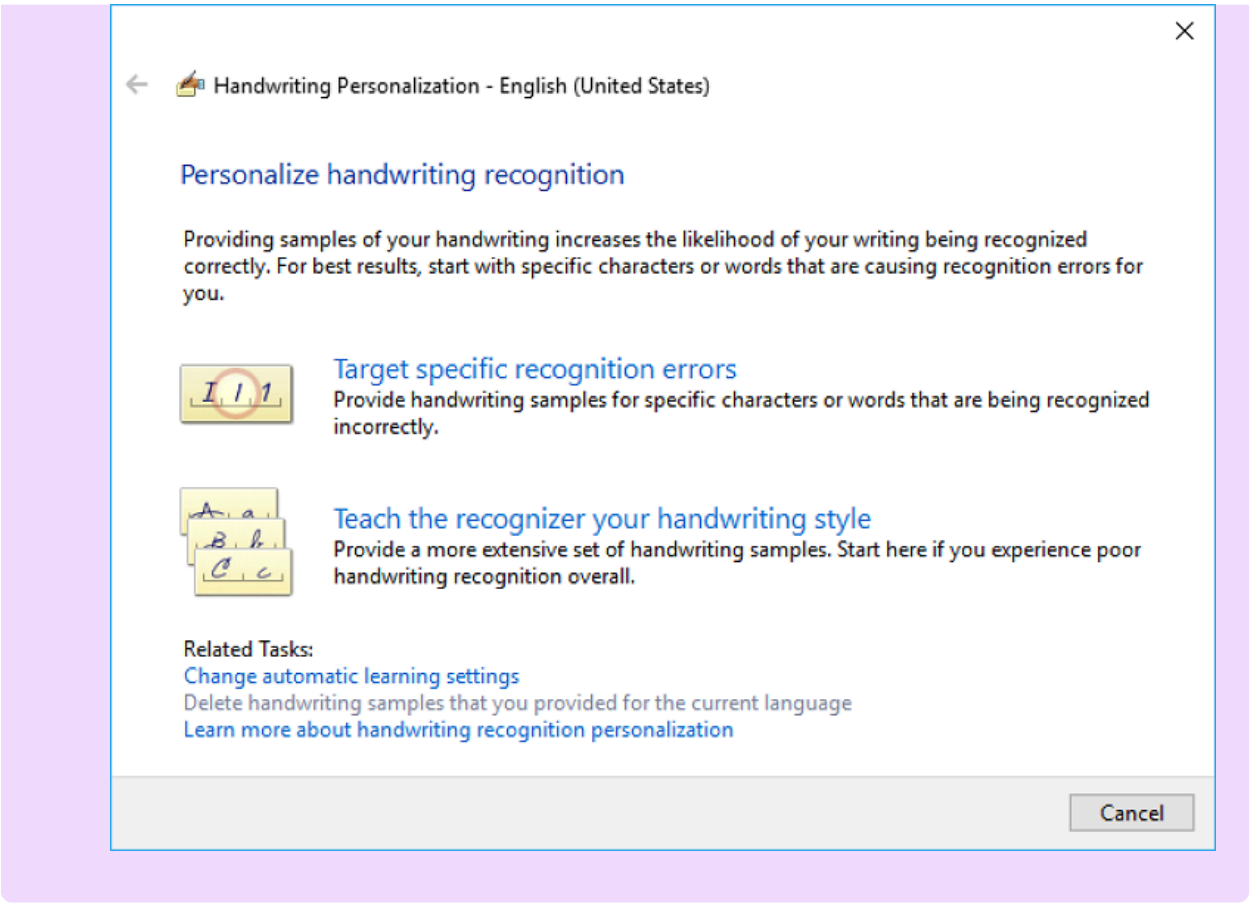
> 3. Select **Get to know my handwriting** to open the **Handwriting Personalization** dialog.



In the sample:

1. Open the MainPage.xaml file.
2. Find the code marked with the title of this step ("<!-- Step 5: Support handwriting recognition -->").
3. Uncomment the following lines.

XAML

```
<Button x:Name="recognizeText"
        Content="Recognize text"
        Grid.Row="0" Grid.Column="0"
        Margin="10,10,10,10"
        Click="recognizeText_ClickAsync"/>
<TextBlock x:Name="recognitionResult"
           Text="Recognition results: "
           VerticalAlignment="Center"
           Grid.Row="0" Grid.Column="1"
           Margin="50,0,0,0" />
```

4. Open the MainPage.xaml.cs file.
5. Find the code marked with the title of this step (" Step 5: Support handwriting recognition").
6. Uncomment the following lines.

- These are the global variables required for this step.

C#

```
    InkAnalyzer analyzerText = new InkAnalyzer();
    IReadOnlyList<InkStroke> strokesText = null;
    InkAnalysisResult resultText = null;
    IReadOnlyList<IInkAnalysisNode> words = null;
```

- This is the handler for the **Recognize text** button, where we do the recognition processing.

C#

```
    private async void recognizeText_ClickAsync(object sender,
RoutedEventArgs e)
    {
        strokesText = inkCanvas.InkPresenter.StrokeContainer.GetStrokes();
        // Ensure an ink stroke is present.
        if (strokesText.Count > 0)
        {
            analyzerText.AddDataForStrokes(strokesText);

            resultText = await analyzerText.AnalyzeAsync();

            if (resultText.Status == InkAnalysisStatus.Updated)
            {
                words =
analyzerText.AnalysisRoot.FindNodes(InkAnalysisNodeKind.InkWord);
                foreach (var word in words)
                {
                    InkAnalysisInkWord concreteWord =
(InkAnalysisInkWord)word;
                    foreach (string s in concreteWord.TextAlternates)
                    {
                        recognitionResult.Text += s;
                    }
                }
            }
            analyzerText.ClearDataForAllStrokes();
        }
    }
```

7. Run the app again, write something, and then click the **Recognize text** button
8. The results of the recognition are displayed beside the button

Challenge 1: International recognition

Windows Ink supports text recognition for many of the of the languages supported by Windows. Each language pack includes a handwriting recognition engine that can be installed with the language pack.

Target a specific language by querying the installed handwriting recognition engines.

For more details about international handwriting recognition, see Recognize Windows Ink strokes as text.

Challenge 2: Dynamic recognition

For this tutorial, we require that a button be pressed to initiate recognition. You can also perform dynamic recognition by using a basic timing function.

For more details about dynamic recognition, see Recognize Windows Ink strokes as text.

Step 6: Recognize shapes

Ok, so now you can convert your handwritten notes into something a little more legible. But what about those shaky, caffeinated doodles from your morning Flowcharters Anonymous meeting?

Using ink analysis, your app can also recognize a set of core shapes, including:

- Circle
- Diamond
- Drawing
- Ellipse
- EquilateralTriangle
- Hexagon
- IsoscelesTriangle
- Parallelogram
- Pentagon
- Quadrilateral
- Rectangle
- RightTriangle
- Square
- Trapezoid
- Triangle

In this step, we use the shape-recognition features of Windows Ink to try to clean up your doodles.

For this example, we don't attempt to redraw ink strokes (although that's possible). Instead, we add a standard canvas under the InkCanvas where we draw equivalent Ellipse or Polygon objects derived from the original ink. We then delete the corresponding ink strokes.

In the sample:

1. Open the MainPage.xaml file
2. Find the code marked with the title of this step ("<!-- Step 6: Recognize shapes -->")
3. Uncomment this line.

XAML

```
   <Canvas x:Name="canvas" />

   And these lines.

    <Button Grid.Row="1" x:Name="recognizeShape"
Click="recognizeShape_ClickAsync"
        Content="Recognize shape"
        Margin="10,10,10,10" />
```

4. Open the MainPage.xaml.cs file
5. Find the code marked with the title of this step ("// Step 6: Recognize shapes")
6. Uncomment these lines:

C#

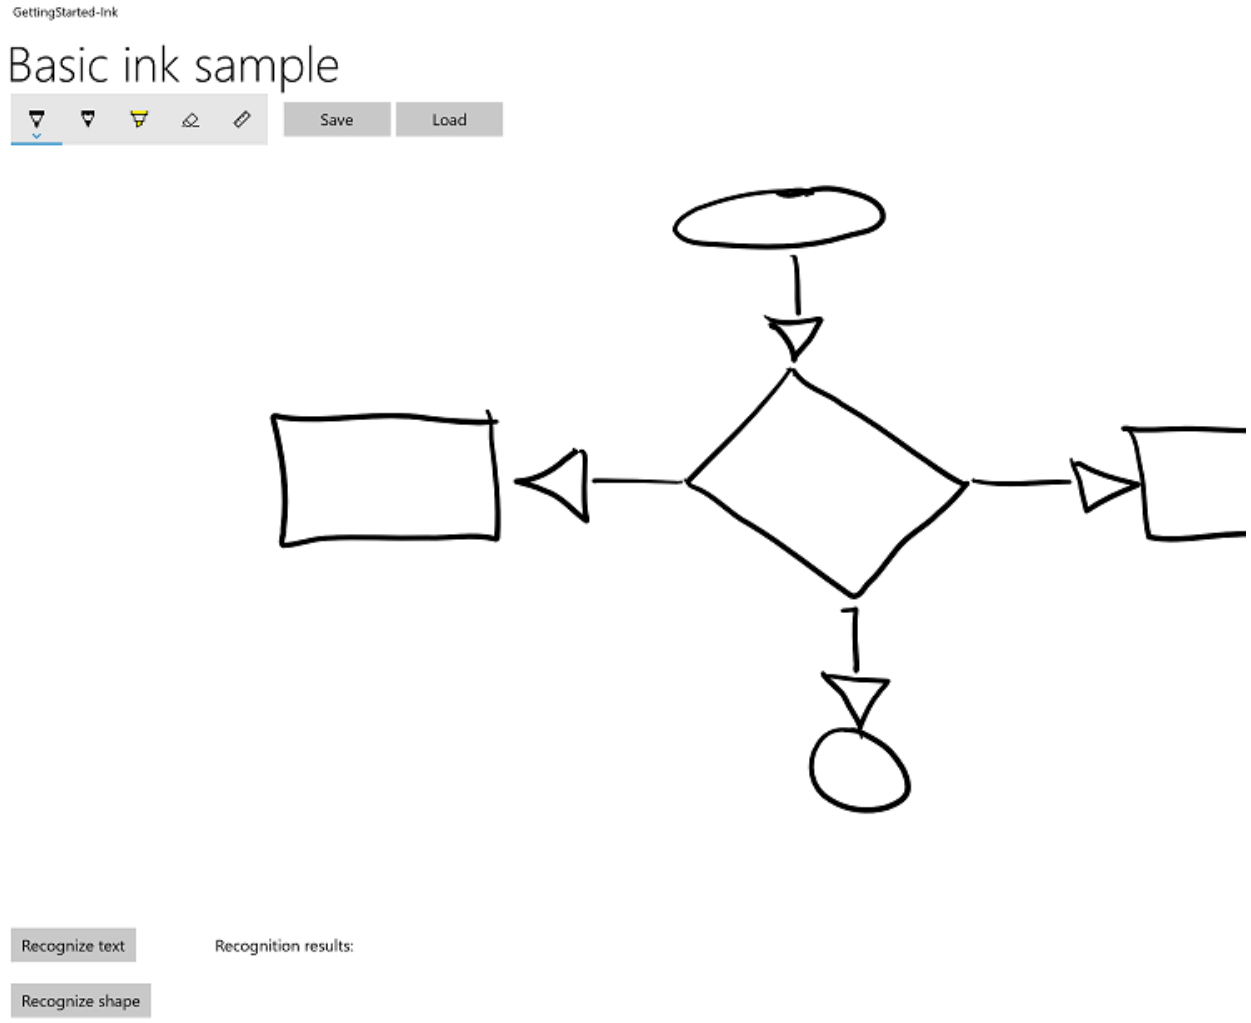
```
    private async void recognizeShape_ClickAsync(object sender,
RoutedEventArgs e)
    {
        ...
    }

    private void DrawEllipse(InkAnalysisInkDrawing shape)
    {
        ...
    }

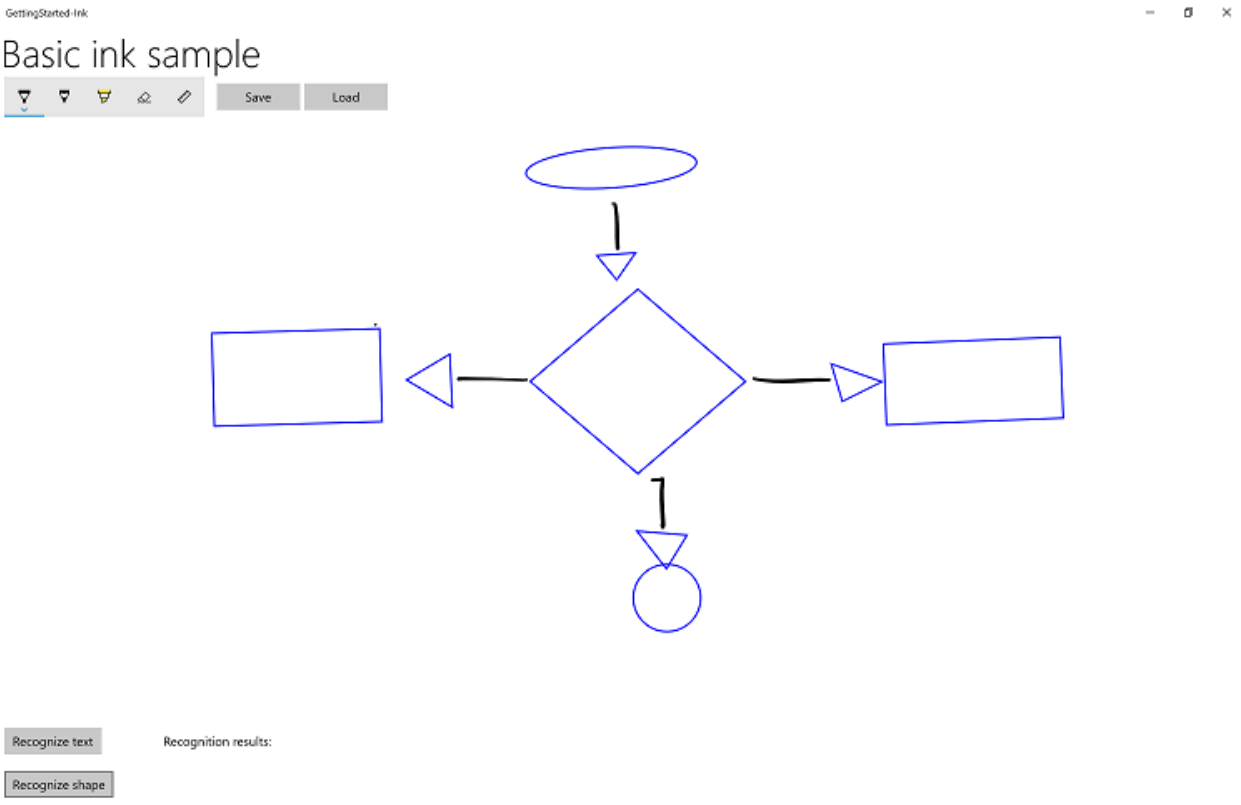
    private void DrawPolygon(InkAnalysisInkDrawing shape)
    {
        ...
    }
```

7. Run the app, draw some shapes, and click the **Recognize shape** button

Here's an example of a rudimentary flowchart from a digital napkin.



Here's the same flowchart after shape recognition.



Step 7: Save and load ink

So, you're done doodling and you like what you see, but think you might like to tweak a couple of things later? You can save your ink strokes to an Ink Serialized Format (ISF) file and load them for editing whenever the inspiration strikes.

The ISF file is a basic GIF image that includes additional metadata describing ink-stroke properties and behaviors. Apps that are not ink enabled can ignore the extra metadata and still load the basic GIF image (including alpha-channel background transparency).

> **Note**
>
> The Ink Serialized Format (ISF) Specification can be downloaded from the Microsoft Download Center.

In this step, we hook up the **Save** and **Load** buttons located beside the ink toolbar.

In the sample:

1. Open the MainPage.xaml file.
2. Find the code marked with the title of this step ("<!-- Step 7: Saving and loading ink -->").
3. Uncomment the following lines.

XAML

```
    <Button x:Name="buttonSave"
            Content="Save"
            Click="buttonSave_ClickAsync"
            Width="100"
            Margin="5,0,0,0"/>
    <Button x:Name="buttonLoad"
            Content="Load"
            Click="buttonLoad_ClickAsync"
            Width="100"
            Margin="5,0,0,0"/>
```

4. Open the MainPage.xaml.cs file.
5. Find the code marked with the title of this step ("// Step 7: Save and load ink").
6. Uncomment the following lines.

C#

```
    private async void buttonSave_ClickAsync(object sender, RoutedEventArgs
e)
    {
        ...
    }

    private async void buttonLoad_ClickAsync(object sender, RoutedEventArgs
e)
    {
        ...
    }
```

7. Run the app and draw something.
8. Select the **Save** button and save your drawing.
9. Erase the ink or restart the app.
10. Select the **Load** button and open the ink file you just saved.

Challenge: Use the clipboard to copy and paste ink strokes

Windows ink also supports copying and pasting ink strokes to and from the clipboard.

For more details about using the clipboard with ink, see Store and retrieve Windows Ink stroke data.

Summary

Congratulations, you've completed the **Input: Support ink in your Windows app** tutorial ! We showed you the basic code required for supporting ink in your Windows apps, and how to provide some of the richer user experiences supported by the Windows Ink platform.

Recognize Windows Ink strokes as text and shapes

Article • 06/24/2021

Convert ink strokes to text and shapes using the recognition capabilities built into Windows Ink.

> **Important APIs**: InkCanvas, Windows.UI.Input.Inking

Free-form recognition with ink analysis

Here, we demonstrate how to use the Windows Ink analysis engine (Windows.UI.Input.Inking.Analysis) to classify, analyze, and recognize a set of free-form strokes on an **InkCanvas** as either text or shapes. (In addition to text and shape recognition, ink analysis can also be used to recognize document structure, bullet lists, and generic drawings.)

> ⓘ **Note**
>
> For basic, single-line, plain text scenarios such as form input, see **Constrained handwriting recognition** later in this topic.

In this example, recognition is initiated when the user clicks a button to indicate they are finished drawing.

Download this sample from Ink analysis sample (basic)

1. First, we set up the UI (MainPage.xaml).

   The UI includes a "Recognize" button, an **InkCanvas**, and a standard **Canvas**. When the "Recognize" button is pressed, all ink strokes on the ink canvas are analyzed and (if recognized) corresponding shapes and text are drawn on the standard canvas. The original ink strokes are then deleted from the ink canvas.

   XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
     <Grid.RowDefinitions>
         <RowDefinition Height="Auto"/>
         <RowDefinition Height="*"/>
     </Grid.RowDefinitions>
     <StackPanel x:Name="HeaderPanel"
```

```
                Orientation="Horizontal"
                Grid.Row="0">
        <TextBlock x:Name="Header"
                   Text="Basic ink analysis sample"
                   Style="{ThemeResource HeaderTextBlockStyle}"
                   Margin="10,0,0,0" />
        <Button x:Name="recognize"
                Content="Recognize"
                Margin="50,0,10,0"/>
    </StackPanel>
    <Grid x:Name="drawingCanvas" Grid.Row="1">

        <!-- The canvas where we render the replacement text and
shapes. -->
        <Canvas x:Name="recognitionCanvas" />
        <!-- The canvas for ink input. -->
        <InkCanvas x:Name="inkCanvas" />

    </Grid>
</Grid>
```

2. In the UI code-behind file (MainPage.xaml.cs), add the namespace type references required for our ink and ink analysis functionality:

   - Windows.UI.Input.Inking
   - Windows.UI.Input.Inking.Analysis
   - Windows.UI.Xaml.Shapes

3. We then specify our global variables:

C#

```
InkAnalyzer inkAnalyzer = new InkAnalyzer();
IReadOnlyList<InkStroke> inkStrokes = null;
InkAnalysisResult inkAnalysisResults = null;
```

4. Next, we set some basic ink input behaviors:

   - The **InkPresenter** is configured to interpret input data from pen, mouse, and touch as ink strokes (**InputDeviceTypes**).
   - Ink strokes are rendered on the **InkCanvas** using the specified **InkDrawingAttributes**.
   - A listener for the click event on the "Recognize" button is also declared.

C#

```
/// <summary>
/// Initialize the UI page.
/// </summary>
```

```
public MainPage()
{
    this.InitializeComponent();

    // Set supported inking device types.
    inkCanvas.InkPresenter.InputDeviceTypes =
        Windows.UI.Core.CoreInputDeviceTypes.Mouse |
        Windows.UI.Core.CoreInputDeviceTypes.Pen |
        Windows.UI.Core.CoreInputDeviceTypes.Touch;

    // Set initial ink stroke attributes.
    InkDrawingAttributes drawingAttributes = new
InkDrawingAttributes();
    drawingAttributes.Color = Windows.UI.Colors.Black;
    drawingAttributes.IgnorePressure = false;
    drawingAttributes.FitToCurve = true;

inkCanvas.InkPresenter.UpdateDefaultDrawingAttributes(drawingAttributes
);

    // Listen for button click to initiate recognition.
    recognize.Click += RecognizeStrokes_Click;
}
```

5. For this example, we perform the ink analysis in the click event handler of the "Recognize" button.

    - First, call **GetStrokes** on the **StrokeContainer** of the **InkCanvas.InkPresenter** to get the collection of all current ink strokes.
    - If ink strokes are present, pass them in a call to **AddDataForStrokes** of the InkAnalyzer.
    - We're trying to recognize both drawings and text, but you can use the **SetStrokeDataKind** method to specify whether you're interested only in text (including document structure and bullet lists) or only in drawings (including shape recognition).
    - Call **AnalyzeAsync** to initiate ink analysis and get the **InkAnalysisResult**.
    - If **Status** returns a state of **Updated**, call **FindNodes** for both **InkAnalysisNodeKind.InkWord** and **InkAnalysisNodeKind.InkDrawing**.
    - Iterate through both sets of node types and draw the respective text or shape on the recognition canvas (below the ink canvas).
    - Finally, delete the recognized nodes from the InkAnalyzer and the corresponding ink strokes from the ink canvas.

C#

```
/// <summary>
/// The "Analyze" button click handler.
/// Ink recognition is performed here.
```

```
/// </summary>
/// <param name="sender">Source of the click event</param>
/// <param name="e">Event args for the button click routed
event</param>
private async void RecognizeStrokes_Click(object sender,
RoutedEventArgs e)
{
    inkStrokes = inkCanvas.InkPresenter.StrokeContainer.GetStrokes();
    // Ensure an ink stroke is present.
    if (inkStrokes.Count > 0)
    {
        inkAnalyzer.AddDataForStrokes(inkStrokes);

        // In this example, we try to recognizing both
        // writing and drawing, so the platform default
        // of "InkAnalysisStrokeKind.Auto" is used.
        // If you're only interested in a specific type of recognition,
        // such as writing or drawing, you can constrain recognition
        // using the SetStrokDataKind method as follows:
        // foreach (var stroke in strokesText)
        // {
        //     analyzerText.SetStrokeDataKind(
        //      stroke.Id, InkAnalysisStrokeKind.Writing);
        // }
        // This can improve both efficiency and recognition results.
        inkAnalysisResults = await inkAnalyzer.AnalyzeAsync();

        // Have ink strokes on the canvas changed?
        if (inkAnalysisResults.Status == InkAnalysisStatus.Updated)
        {
            // Find all strokes that are recognized as handwriting and
            // create a corresponding ink analysis InkWord node.
            var inkwordNodes =
                inkAnalyzer.AnalysisRoot.FindNodes(
                    InkAnalysisNodeKind.InkWord);

            // Iterate through each InkWord node.
            // Draw primary recognized text on recognitionCanvas
            // (for this example, we ignore alternatives), and delete
            // ink analysis data and recognized strokes.
            foreach (InkAnalysisInkWord node in inkwordNodes)
            {
                // Draw a TextBlock object on the recognitionCanvas.
                DrawText(node.RecognizedText, node.BoundingRect);

                foreach (var strokeId in node.GetStrokeIds())
                {
                    var stroke =

inkCanvas.InkPresenter.StrokeContainer.GetStrokeById(strokeId);
                    stroke.Selected = true;
                }
                inkAnalyzer.RemoveDataForStrokes(node.GetStrokeIds());
            }
            inkCanvas.InkPresenter.StrokeContainer.DeleteSelected();
```

```
            // Find all strokes that are recognized as a drawing and
            // create a corresponding ink analysis InkDrawing node.
            var inkdrawingNodes =
                inkAnalyzer.AnalysisRoot.FindNodes(
                    InkAnalysisNodeKind.InkDrawing);
            // Iterate through each InkDrawing node.
            // Draw recognized shapes on recognitionCanvas and
            // delete ink analysis data and recognized strokes.
            foreach (InkAnalysisInkDrawing node in inkdrawingNodes)
            {
                if (node.DrawingKind == InkAnalysisDrawingKind.Drawing)
                {
                    // Catch and process unsupported shapes (lines and
so on) here.
                }
                // Process generalized shapes here (ellipses and
polygons).
                else
                {
                    // Draw an Ellipse object on the recognitionCanvas
(circle is a specialized ellipse).
                    if (node.DrawingKind ==
InkAnalysisDrawingKind.Circle || node.DrawingKind ==
InkAnalysisDrawingKind.Ellipse)
                    {
                        DrawEllipse(node);
                    }
                    // Draw a Polygon object on the recognitionCanvas.
                    else
                    {
                        DrawPolygon(node);
                    }
                    foreach (var strokeId in node.GetStrokeIds())
                    {
                        var stroke =
inkCanvas.InkPresenter.StrokeContainer.GetStrokeById(strokeId);
                        stroke.Selected = true;
                    }
                }
                inkAnalyzer.RemoveDataForStrokes(node.GetStrokeIds());
            }
            inkCanvas.InkPresenter.StrokeContainer.DeleteSelected();
        }
    }
}
```

6. Here's the function for drawing a TextBlock on our recognition canvas. We use the bounding rectangle of the associated ink stroke on the ink canvas to set the position and font size of the TextBlock.

```
C#
```

```
 /// <summary>
 /// Draw ink recognition text string on the recognitionCanvas.
 /// </summary>
 /// <param name="recognizedText">The string returned by text
recognition.</param>
 /// <param name="boundingRect">The bounding rect of the original ink
writing.</param>
 private void DrawText(string recognizedText, Rect boundingRect)
 {
     TextBlock text = new TextBlock();
     Canvas.SetTop(text, boundingRect.Top);
     Canvas.SetLeft(text, boundingRect.Left);

     text.Text = recognizedText;
     text.FontSize = boundingRect.Height;

     recognitionCanvas.Children.Add(text);
 }
```

7. Here are the functions for drawing ellipses and polygons on our recognition canvas. We use the bounding rectangle of the associated ink stroke on the ink canvas to set the position and font size of the shapes.

C#

```
 // Draw an ellipse on the recognitionCanvas.
 private void DrawEllipse(InkAnalysisInkDrawing shape)
 {
     var points = shape.Points;
     Ellipse ellipse = new Ellipse();

     ellipse.Width = shape.BoundingRect.Width;
     ellipse.Height = shape.BoundingRect.Height;

     Canvas.SetTop(ellipse, shape.BoundingRect.Top);
     Canvas.SetLeft(ellipse, shape.BoundingRect.Left);

     var brush = new
SolidColorBrush(Windows.UI.ColorHelper.FromArgb(255, 0, 0, 255));
     ellipse.Stroke = brush;
     ellipse.StrokeThickness = 2;
     recognitionCanvas.Children.Add(ellipse);
 }

 // Draw a polygon on the recognitionCanvas.
 private void DrawPolygon(InkAnalysisInkDrawing shape)
 {
     List<Point> points = new List<Point>(shape.Points);
     Polygon polygon = new Polygon();

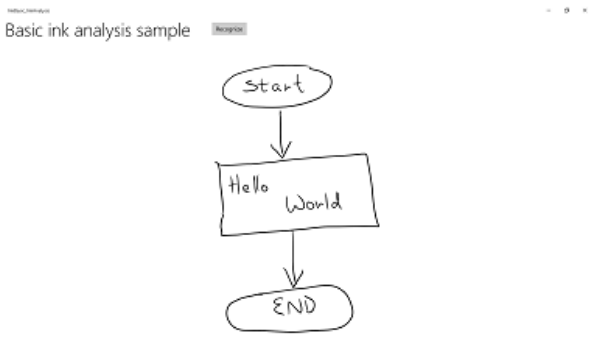
     foreach (Point point in points)
     {
```

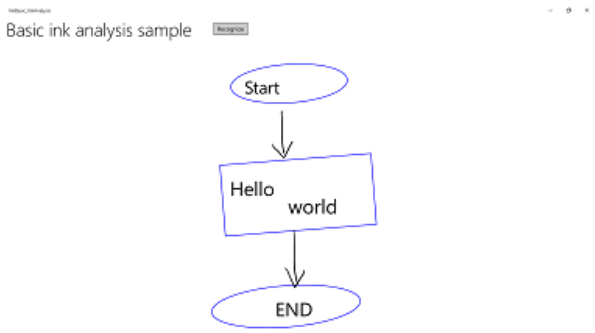
```
            polygon.Points.Add(point);
        }

        var brush = new
SolidColorBrush(Windows.UI.ColorHelper.FromArgb(255, 0, 0, 255));
        polygon.Stroke = brush;
        polygon.StrokeThickness = 2;
        recognitionCanvas.Children.Add(polygon);
    }
```

Here's this sample in action:

Expand table

Before analysis	After analysis
	




Constrained handwriting recognition

In the preceding section (Free-form recognition with ink analysis), we demonstrated how to use the ink analysis APIs to analyze and recognize arbitrary ink strokes within an InkCanvas area.

In this section, we demonstrate how to use the Windows Ink handwriting recognition engine (not ink analysis) to convert a set of strokes on an **InkCanvas** to text (based on the installed default language pack).

> **Note**
>
> The basic handwriting recognition shown in this section is best suited for single-line, text input scenarios such as form input. For richer recognition scenarios that include analysis and interpretation of document structure, list items, shapes, and drawings (in addition to text recognition), see the previous section: **Free-form recognition with ink analysis**.

In this example, recognition is initiated when the user clicks a button to indicate they are finished writing.

Download this sample from Ink handwriting recognition sample

1. First, we set up the UI.

   The UI includes a "Recognize" button, the **InkCanvas**, and an area to display recognition results.

   XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
     <Grid.RowDefinitions>
         <RowDefinition Height="Auto"/>
         <RowDefinition Height="*"/>
     </Grid.RowDefinitions>
     <StackPanel x:Name="HeaderPanel"
                 Orientation="Horizontal"
                 Grid.Row="0">
             <TextBlock x:Name="Header"
                 Text="Basic ink recognition sample"
                 Style="{ThemeResource HeaderTextBlockStyle}"
                 Margin="10,0,0,0" />
             <Button x:Name="recognize"
                 Content="Recognize"
                 Margin="50,0,10,0"/>
     </StackPanel>
     <Grid Grid.Row="1">
         <Grid.RowDefinitions>
             <RowDefinition Height="*"/>
             <RowDefinition Height="Auto"/>
         </Grid.RowDefinitions>
         <InkCanvas x:Name="inkCanvas"
             Grid.Row="0"/>
         <TextBlock x:Name="recognitionResult"
             Grid.Row="1"
             Margin="50,0,10,0"/>
     </Grid>
 </Grid>
```

2. For this example, you need to first add the namespace type references required for our ink functionality:

   - Windows.UI.Input
   - Windows.UI.Input.Inking

3. We then set some basic ink input behaviors.

The InkPresenter is configured to interpret input data from both pen and mouse as ink strokes (InputDeviceTypes). Ink strokes are rendered on the InkCanvas using the specified InkDrawingAttributes. A listener for the click event on the "Recognize" button is also declared.

C#

```
public MainPage()
    {
        this.InitializeComponent();

        // Set supported inking device types.
        inkCanvas.InkPresenter.InputDeviceTypes =
            Windows.UI.Core.CoreInputDeviceTypes.Mouse |
            Windows.UI.Core.CoreInputDeviceTypes.Pen;

        // Set initial ink stroke attributes.
        InkDrawingAttributes drawingAttributes = new
InkDrawingAttributes();
        drawingAttributes.Color = Windows.UI.Colors.Black;
        drawingAttributes.IgnorePressure = false;
        drawingAttributes.FitToCurve = true;

inkCanvas.InkPresenter.UpdateDefaultDrawingAttributes(drawingAttributes
);

        // Listen for button click to initiate recognition.
        recognize.Click += Recognize_Click;
    }
```

4. Finally, we perform the basic handwriting recognition. For this example, we use the click event handler of the "Recognize" button to perform the handwriting recognition.

    - An InkPresenter stores all ink strokes in an InkStrokeContainer object. The strokes are exposed through the StrokeContainer property of the **InkPresenter** and retrieved using the GetStrokes method.

    C#

    ```
    // Get all strokes on the InkCanvas.
        IReadOnlyList<InkStroke> currentStrokes =
    inkCanvas.InkPresenter.StrokeContainer.GetStrokes();
    ```

    - An InkRecognizerContainer is created to manage the handwriting recognition process.

    C#

```
// Create a manager for the InkRecognizer object
    // used in handwriting recognition.
    InkRecognizerContainer inkRecognizerContainer =
        new InkRecognizerContainer();
```

- RecognizeAsync is called to retrieve a set of InkRecognitionResult objects. Recognition results are produced for each word that is detected by an InkRecognizer.

C#

```
// Recognize all ink strokes on the ink canvas.
    IReadOnlyList<InkRecognitionResult> recognitionResults =
        await inkRecognizerContainer.RecognizeAsync(
            inkCanvas.InkPresenter.StrokeContainer,
            InkRecognitionTarget.All);
```

- Each InkRecognitionResult object contains a set of text candidates. The topmost item in this list is considered by the recognition engine to be the best match, followed by the remaining candidates in order of decreasing confidence.

  We iterate through each InkRecognitionResult and compile the list of candidates. The candidates are then displayed and the InkStrokeContainer is cleared (which also clears the InkCanvas).

C#

```
string str = "Recognition result\n";
    // Iterate through the recognition results.
    foreach (var result in recognitionResults)
    {
        // Get all recognition candidates from each recognition result.
        IReadOnlyList<string> candidates = result.GetTextCandidates();
        str += "Candidates: " + candidates.Count.ToString() + "\n";
        foreach (string candidate in candidates)
        {
            str += candidate + " ";
        }
    }
    // Display the recognition candidates.
    recognitionResult.Text = str;
    // Clear the ink canvas once recognition is complete.
    inkCanvas.InkPresenter.StrokeContainer.Clear();
```

- Here's the click handler example, in full.

C#

```
// Handle button click to initiate recognition.
    private async void Recognize_Click(object sender, RoutedEventArgs
e)
    {
        // Get all strokes on the InkCanvas.
        IReadOnlyList<InkStroke> currentStrokes =
inkCanvas.InkPresenter.StrokeContainer.GetStrokes();

        // Ensure an ink stroke is present.
        if (currentStrokes.Count > 0)
        {
            // Create a manager for the InkRecognizer object
            // used in handwriting recognition.
            InkRecognizerContainer inkRecognizerContainer =
                new InkRecognizerContainer();

            // inkRecognizerContainer is null if a recognition engine
is not available.
            if (!(inkRecognizerContainer == null))
            {
                // Recognize all ink strokes on the ink canvas.
                IReadOnlyList<InkRecognitionResult> recognitionResults
=
                    await inkRecognizerContainer.RecognizeAsync(
                        inkCanvas.InkPresenter.StrokeContainer,
                        InkRecognitionTarget.All);
                // Process and display the recognition results.
                if (recognitionResults.Count > 0)
                {
                    string str = "Recognition result\n";
                    // Iterate through the recognition results.
                    foreach (var result in recognitionResults)
                    {
                        // Get all recognition candidates from each
recognition result.
                        IReadOnlyList<string> candidates =
result.GetTextCandidates();
                        str += "Candidates: " +
candidates.Count.ToString() + "\n";
                        foreach (string candidate in candidates)
                        {
                            str += candidate + " ";
                        }
                    }
                    // Display the recognition candidates.
                    recognitionResult.Text = str;
                    // Clear the ink canvas once recognition is
complete.
                    inkCanvas.InkPresenter.StrokeContainer.Clear();
                }
                else
                {
```

```
                    recognitionResult.Text = "No recognition results.";
                }
            }
            else
            {
                Windows.UI.Popups.MessageDialog messageDialog = new
Windows.UI.Popups.MessageDialog("You must install handwriting
recognition engine.");
                await messageDialog.ShowAsync();
            }
        }
        else
        {
            recognitionResult.Text = "No ink strokes to recognize.";
        }
    }
```

International recognition

The handwriting recognition built into the Windows ink platform includes an extensive subset of locales and languages supported by Windows.

See the InkRecognizer.Name property topic for a list of languages supported by the InkRecognizer .

Your app can query the set of installed handwriting recognition engines and use one of those, or let a user select their preferred language.

Note Users can see a list of installed languages by going to **Settings -> Time & Language**. Installed languages are listed under **Languages**.

To install new language packs and enable handwriting recognition for that language:

1. Go to **Settings** > **Time & language** > **Region & language**.
2. Select **Add a language**.
3. Select a language from the list, then choose the region version. The language is now listed on the **Region & language** page.
4. Click the language and select **Options**.
5. On the **Language options** page, download the **Handwriting recognition engine** (they can also download the full language pack, speech recognition engine, and keyboard layout here).

Here, we demonstrate how to use the handwriting recognition engine to interpret a set of strokes on an InkCanvas based on the selected recognizer.

The recognition is initiated by the user clicking a button when they are finished writing.

1. First, we set up the UI.

   The UI includes a "Recognize" button, a combo box that lists all installed handwriting recognizers, the **InkCanvas**, and an area to display recognition results.

   XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto"/>
            <RowDefinition Height="*"/>
        </Grid.RowDefinitions>
        <StackPanel x:Name="HeaderPanel"
                    Orientation="Horizontal"
                    Grid.Row="0">
            <TextBlock x:Name="Header"
                       Text="Advanced international ink recognition
sample"
                       Style="{ThemeResource HeaderTextBlockStyle}"
                       Margin="10,0,0,0" />
            <ComboBox x:Name="comboInstalledRecognizers"
                      Margin="50,0,10,0">
                <ComboBox.ItemTemplate>
                    <DataTemplate>
                        <StackPanel Orientation="Horizontal">
                            <TextBlock Text="{Binding Name}" />
                        </StackPanel>
                    </DataTemplate>
                </ComboBox.ItemTemplate>
            </ComboBox>
            <Button x:Name="buttonRecognize"
                    Content="Recognize"
                    IsEnabled="False"
                    Margin="50,0,10,0"/>
        </StackPanel>
        <Grid Grid.Row="1">
            <Grid.RowDefinitions>
                <RowDefinition Height="*"/>
                <RowDefinition Height="Auto"/>
            </Grid.RowDefinitions>
            <InkCanvas x:Name="inkCanvas"
                       Grid.Row="0"/>
            <TextBlock x:Name="recognitionResult"
                       Grid.Row="1"
                       Margin="50,0,10,0"/>
        </Grid>
    </Grid>
```

2. We then set some basic ink input behaviors.

   The **InkPresenter** is configured to interpret input data from both pen and mouse as ink strokes (**InputDeviceTypes**). Ink strokes are rendered on the **InkCanvas** using

the specified InkDrawingAttributes.

We call an `InitializeRecognizerList` function to populate the recognizer combo box with a list of installed handwriting recognizers.

We also declare listeners for the click event on the "Recognize" button and the selection changed event on the recognizer combo box.

C#

```
 public MainPage()
 {
    this.InitializeComponent();

    // Set supported inking device types.
    inkCanvas.InkPresenter.InputDeviceTypes =
        Windows.UI.Core.CoreInputDeviceTypes.Mouse |
        Windows.UI.Core.CoreInputDeviceTypes.Pen;

    // Set initial ink stroke attributes.
    InkDrawingAttributes drawingAttributes = new
InkDrawingAttributes();
    drawingAttributes.Color = Windows.UI.Colors.Black;
    drawingAttributes.IgnorePressure = false;
    drawingAttributes.FitToCurve = true;

inkCanvas.InkPresenter.UpdateDefaultDrawingAttributes(drawingAttributes
);

    // Populate the recognizer combo box with installed recognizers.
    InitializeRecognizerList();

    // Listen for combo box selection.
    comboInstalledRecognizers.SelectionChanged +=
        comboInstalledRecognizers_SelectionChanged;

    // Listen for button click to initiate recognition.
    buttonRecognize.Click += Recognize_Click;
}
```

3. We populate the recognizer combo box with a list of installed handwriting recognizers.

   An InkRecognizerContainer is created to manage the handwriting recognition process. Use this object to call GetRecognizers and retrieve the list of installed recognizers to populate the recognizer combo box.

   C#

```
// Populate the recognizer combo box with installed recognizers.
private void InitializeRecognizerList()
{
    // Create a manager for the handwriting recognition process.
    inkRecognizerContainer = new InkRecognizerContainer();
    // Retrieve the collection of installed handwriting recognizers.
    IReadOnlyList<InkRecognizer> installedRecognizers =
        inkRecognizerContainer.GetRecognizers();
    // inkRecognizerContainer is null if a recognition engine is not
available.
    if (!(inkRecognizerContainer == null))
    {
        comboInstalledRecognizers.ItemsSource = installedRecognizers;
        buttonRecognize.IsEnabled = true;
    }
}
```

4. Update the handwriting recognizer if the recognizer combo box selection changes.

   Use the InkRecognizerContainer to call SetDefaultRecognizer based on the selected recognizer from the recognizer combo box.

   C#

   ```
   // Handle recognizer change.
       private void comboInstalledRecognizers_SelectionChanged(
           object sender, SelectionChangedEventArgs e)
       {
           inkRecognizerContainer.SetDefaultRecognizer(
               (InkRecognizer)comboInstalledRecognizers.SelectedItem);
       }
   ```

5. Finally, we perform the handwriting recognition based on the selected handwriting recognizer. For this example, we use the click event handler of the "Recognize" button to perform the handwriting recognition.

   - An InkPresenter stores all ink strokes in an InkStrokeContainer object. The strokes are exposed through the StrokeContainer property of the **InkPresenter** and retrieved using the GetStrokes method.

   C#

   ```
   // Get all strokes on the InkCanvas.
       IReadOnlyList<InkStroke> currentStrokes =
           inkCanvas.InkPresenter.StrokeContainer.GetStrokes();
   ```

   - RecognizeAsync is called to retrieve a set of InkRecognitionResult objects.

Recognition results are produced for each word that is detected by an InkRecognizer.

```
C#

// Recognize all ink strokes on the ink canvas.
IReadOnlyList<InkRecognitionResult> recognitionResults =
    await inkRecognizerContainer.RecognizeAsync(
        inkCanvas.InkPresenter.StrokeContainer,
        InkRecognitionTarget.All);
```

- Each InkRecognitionResult object contains a set of text candidates. The topmost item in this list is considered by the recognition engine to be the best match, followed by the remaining candidates in order of decreasing confidence.

  We iterate through each InkRecognitionResult and compile the list of candidates. The candidates are then displayed and the InkStrokeContainer is cleared (which also clears the InkCanvas).

```
C#

string str = "Recognition result\n";
// Iterate through the recognition results.
foreach (InkRecognitionResult result in recognitionResults)
{
        // Get all recognition candidates from each recognition result.
        IReadOnlyList<string> candidates =
            result.GetTextCandidates();
        str += "Candidates: " + candidates.Count.ToString() + "\n";
        foreach (string candidate in candidates)
        {
            str += candidate + " ";
        }
}
// Display the recognition candidates.
recognitionResult.Text = str;
// Clear the ink canvas once recognition is complete.
inkCanvas.InkPresenter.StrokeContainer.Clear();
```

- Here's the click handler example, in full.

```
C#

// Handle button click to initiate recognition.
private async void Recognize_Click(object sender, RoutedEventArgs e)
{
    // Get all strokes on the InkCanvas.
    IReadOnlyList<InkStroke> currentStrokes =
```

```
        inkCanvas.InkPresenter.StrokeContainer.GetStrokes();

    // Ensure an ink stroke is present.
    if (currentStrokes.Count > 0)
    {
        // inkRecognizerContainer is null if a recognition engine is
not available.
        if (!(inkRecognizerContainer == null))
        {
            // Recognize all ink strokes on the ink canvas.
            IReadOnlyList<InkRecognitionResult> recognitionResults =
                await inkRecognizerContainer.RecognizeAsync(
                    inkCanvas.InkPresenter.StrokeContainer,
                    InkRecognitionTarget.All);
            // Process and display the recognition results.
            if (recognitionResults.Count > 0)
            {
                string str = "Recognition result\n";
                // Iterate through the recognition results.
                foreach (InkRecognitionResult result in
recognitionResults)
                {
                    // Get all recognition candidates from each
recognition result.
                    IReadOnlyList<string> candidates =
                        result.GetTextCandidates();
                    str += "Candidates: " + candidates.Count.ToString()
+ "\n";
                    foreach (string candidate in candidates)
                    {
                        str += candidate + " ";
                    }
                }
                // Display the recognition candidates.
                recognitionResult.Text = str;
                // Clear the ink canvas once recognition is complete.
                inkCanvas.InkPresenter.StrokeContainer.Clear();
            }
            else
            {
                recognitionResult.Text = "No recognition results.";
            }
        }
        else
        {
            Windows.UI.Popups.MessageDialog messageDialog =
                new Windows.UI.Popups.MessageDialog(
                    "You must install handwriting recognition
engine.");
            await messageDialog.ShowAsync();
        }
    }
    else
    {
        recognitionResult.Text = "No ink strokes to recognize.";
```

```
    }
}
```

Dynamic recognition

While, the previous two examples require the user to press a button to start recognition, you can also perform dynamic recognition using stroke input paired with a basic timing function.

For this example, we'll use the same UI and stroke settings as the previous international recognition example.

1. These global objects (InkAnalyzer, InkStroke, InkAnalysisResult, DispatcherTimer) are used throughout our app.

```
C#

// Stroke recognition globals.
InkAnalyzer inkAnalyzer;
DispatcherTimer recoTimer;
```

2. Instead of a button to initiate recognition, we add listeners for two **InkPresenter** stroke events (**StrokesCollected** and **StrokeStarted**), and set up a basic timer (**DispatcherTimer**) with a one second **Tick** interval.

```
C#

public MainPage()
{
    this.InitializeComponent();

    // Set supported inking device types.
    inkCanvas.InkPresenter.InputDeviceTypes =
        Windows.UI.Core.CoreInputDeviceTypes.Mouse |
        Windows.UI.Core.CoreInputDeviceTypes.Pen;

    // Listen for stroke events on the InkPresenter to
    // enable dynamic recognition.
    // StrokesCollected is fired when the user stops inking by
    // lifting their pen or finger, or releasing the mouse button.
    inkCanvas.InkPresenter.StrokesCollected +=
inkCanvas_StrokesCollected;
    // StrokeStarted is fired when ink input is first detected.
    inkCanvas.InkPresenter.StrokeInput.StrokeStarted +=
        inkCanvas_StrokeStarted;

    inkAnalyzer = new InkAnalyzer();
```

```
    // Timer to manage dynamic recognition.
    recoTimer = new DispatcherTimer();
    recoTimer.Interval = TimeSpan.FromSeconds(1);
    recoTimer.Tick += recoTimer_TickAsync;
}
```

3. We then define the handlers for the InkPresenter events we declared in the first step (we also override the **OnNavigatingFrom** page event to manage our timer).

   - **StrokesCollected**
     Add ink strokes (**AddDataForStrokes**) to the InkAnalyzer and start the recognition timer when the user stops inking (by lifting their pen or finger, or releasing the mouse button). After one second of no ink input, recognition is initiated.

     Use the **SetStrokeDataKind** method to specify whether you're interested only in text (including document structure amd bullet lists) or only in drawings (including shape recognition).

   - **StrokeStarted**
     If a new stroke starts before the next timer tick event, stop the timer as the new stroke is likely the continuation of a single handwriting entry.

C#

```
// Handler for the InkPresenter StrokeStarted event.
// Don't perform analysis while a stroke is in progress.
// If a new stroke starts before the next timer tick event,
// stop the timer as the new stroke is likely the continuation
// of a single handwriting entry.
private void inkCanvas_StrokeStarted(InkStrokeInput sender,
PointerEventArgs args)
{
    recoTimer.Stop();
}
// Handler for the InkPresenter StrokesCollected event.
// Stop the timer and add the collected strokes to the InkAnalyzer.
// Start the recognition timer when the user stops inking (by
// lifting their pen or finger, or releasing the mouse button).
// If ink input is not detected after one second, initiate recognition.
private void inkCanvas_StrokesCollected(InkPresenter sender,
InkStrokesCollectedEventArgs args)
{
    recoTimer.Stop();
    // If you're only interested in a specific type of recognition,
    // such as writing or drawing, you can constrain recognition
    // using the SetStrokDataKind method, which can improve both
    // efficiency and recognition results.
```

```
    // In this example, "InkAnalysisStrokeKind.Writing" is used.
    foreach (var stroke in args.Strokes)
    {
        inkAnalyzer.AddDataForStroke(stroke);
        inkAnalyzer.SetStrokeDataKind(stroke.Id,
InkAnalysisStrokeKind.Writing);
    }
    recoTimer.Start();
}
// Override the Page OnNavigatingFrom event handler to
// stop our timer if user leaves page.
protected override void OnNavigatingFrom(NavigatingCancelEventArgs e)
{
    recoTimer.Stop();
}
```

4. Finally, we perform the handwriting recognition. For this example, we use the **Tick** event handler of a **DispatcherTimer** to initiate the handwriting recognition.

   - Call **AnalyzeAsync** to initiate ink analysis and get the **InkAnalysisResult**.
   - If **Status** returns a state of **Updated**, call **FindNodes** for node types of **InkAnalysisNodeKind.InkWord**.
   - Iterate through the nodes and display the recognized text.
   - Finally, delete the recognized nodes from the InkAnalyzer and the corresponding ink strokes from the ink canvas.

C#

```
private async void recoTimer_TickAsync(object sender, object e)
{
    recoTimer.Stop();
    if (!inkAnalyzer.IsAnalyzing)
    {
        InkAnalysisResult result = await inkAnalyzer.AnalyzeAsync();

        // Have ink strokes on the canvas changed?
        if (result.Status == InkAnalysisStatus.Updated)
        {
            // Find all strokes that are recognized as handwriting and
            // create a corresponding ink analysis InkWord node.
            var inkwordNodes =
                inkAnalyzer.AnalysisRoot.FindNodes(
                    InkAnalysisNodeKind.InkWord);

            // Iterate through each InkWord node.
            // Display the primary recognized text (for this example,
            // we ignore alternatives), and then delete the
            // ink analysis data and recognized strokes.
            foreach (InkAnalysisInkWord node in inkwordNodes)
            {
                string recognizedText = node.RecognizedText;
```

```
                // Display the recognition candidates.
                recognitionResult.Text = recognizedText;

                foreach (var strokeId in node.GetStrokeIds())
                {
                    var stroke =

inkCanvas.InkPresenter.StrokeContainer.GetStrokeById(strokeId);
                    stroke.Selected = true;
                }
                inkAnalyzer.RemoveDataForStrokes(node.GetStrokeIds());
            }
            inkCanvas.InkPresenter.StrokeContainer.DeleteSelected();
        }
    }
    else
    {
        // Ink analyzer is busy. Wait a while and try again.
        recoTimer.Start();
    }
}
```

Store and retrieve Windows Ink stroke data

Article • 07/19/2021

Windows apps that support Windows Ink can serialize and deserialize ink strokes to an Ink Serialized Format (ISF) file. The ISF file is a GIF image with additional metadata for all ink stroke properties and behaviors. Apps that are not ink-enabled, can view the static GIF image, including alpha-channel background transparency.

> **Note**
>
> ISF is the most compact persistent representation of ink. It can be embedded within a binary document format, such as a GIF file, or placed directly on the Clipboard.
>
> The Ink Serialized Format (ISF) Specification can be downloaded from the **Microsoft Download Center**.

> **Important APIs**: InkCanvas, Windows.UI.Input.Inking

Save ink strokes to a file

Here, we demonstrate how to save ink strokes drawn on an **InkCanvas** control.

Download this sample from Save and load ink strokes from an Ink Serialized Format (ISF) file

1. First, we set up the UI.

   The UI includes "Save", "Load", and "Clear" buttons, and the **InkCanvas**.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto"/>
            <RowDefinition Height="*"/>
        </Grid.RowDefinitions>
        <StackPanel x:Name="HeaderPanel" Orientation="Horizontal"
Grid.Row="0">
            <TextBlock x:Name="Header"
                       Text="Basic ink store sample"
                       Style="{ThemeResource HeaderTextBlockStyle}"
                       Margin="10,0,0,0" />
```

```
            <Button x:Name="btnSave"
                    Content="Save"
                    Margin="50,0,10,0"/>
            <Button x:Name="btnLoad"
                    Content="Load"
                    Margin="50,0,10,0"/>
            <Button x:Name="btnClear"
                    Content="Clear"
                    Margin="50,0,10,0"/>
        </StackPanel>
        <Grid Grid.Row="1">
            <InkCanvas x:Name="inkCanvas" />
        </Grid>
    </Grid>
```

2. We then set some basic ink input behaviors.

   The **InkPresenter** is configured to interpret input data from both pen and mouse as ink strokes (**InputDeviceTypes**), and listeners for the click events on the buttons are declared.

C#

```
public MainPage()
    {
        this.InitializeComponent();

        // Set supported inking device types.
        inkCanvas.InkPresenter.InputDeviceTypes =
            Windows.UI.Core.CoreInputDeviceTypes.Mouse |
            Windows.UI.Core.CoreInputDeviceTypes.Pen;

        // Listen for button click to initiate save.
        btnSave.Click += btnSave_Click;
        // Listen for button click to initiate load.
        btnLoad.Click += btnLoad_Click;
        // Listen for button click to clear ink canvas.
        btnClear.Click += btnClear_Click;
    }
```

3. Finally, we save the ink in the click event handler of the **Save** button.

   A **FileSavePicker** lets the user select both the file and the location where the ink data is saved.

   Once a file is selected, we open an **IRandomAccessStream** stream set to **ReadWrite**.

   We then call **SaveAsync** to serialize the ink strokes managed by the **InkStrokeContainer** to the stream.

C#

```
// Save ink data to a file.
    private async void btnSave_Click(object sender, RoutedEventArgs e)
    {
        // Get all strokes on the InkCanvas.
        IReadOnlyList<InkStroke> currentStrokes =
inkCanvas.InkPresenter.StrokeContainer.GetStrokes();

        // Strokes present on ink canvas.
        if (currentStrokes.Count > 0)
        {
            // Let users choose their ink file using a file picker.
            // Initialize the picker.
            Windows.Storage.Pickers.FileSavePicker savePicker =
                new Windows.Storage.Pickers.FileSavePicker();
            savePicker.SuggestedStartLocation =
                Windows.Storage.Pickers.PickerLocationId.DocumentsLibrary;
            savePicker.FileTypeChoices.Add(
                "GIF with embedded ISF",
                new List<string>() { ".gif" });
            savePicker.DefaultFileExtension = ".gif";
            savePicker.SuggestedFileName = "InkSample";

            // Show the file picker.
            Windows.Storage.StorageFile file =
                await savePicker.PickSaveFileAsync();
            // When chosen, picker returns a reference to the selected file.
            if (file != null)
            {
                // Prevent updates to the file until updates are
                // finalized with call to CompleteUpdatesAsync.
                Windows.Storage.CachedFileManager.DeferUpdates(file);
                // Open a file stream for writing.
                IRandomAccessStream stream = await
file.OpenAsync(Windows.Storage.FileAccessMode.ReadWrite);
                // Write the ink strokes to the output stream.
                using (IOutputStream outputStream =
stream.GetOutputStreamAt(0))
                {
                    await
inkCanvas.InkPresenter.StrokeContainer.SaveAsync(outputStream);
                    await outputStream.FlushAsync();
                }
                stream.Dispose();

                // Finalize write so other apps can update file.
                Windows.Storage.Provider.FileUpdateStatus status =
                    await
Windows.Storage.CachedFileManager.CompleteUpdatesAsync(file);

                if (status ==
Windows.Storage.Provider.FileUpdateStatus.Complete)
                {
```

```
                    // File saved.
                }
                else
                {
                    // File couldn't be saved.
                }
            }
            // User selects Cancel and picker returns null.
            else
            {
                // Operation cancelled.
            }
        }
    }
```

> **Note**
>
> GIF is the only file format supported for saving ink data. However, the **LoadAsync** method (demonstrated in the next section) does support additional formats for backward compatibility.

Load ink strokes from a file

Here, we demonstrate how to load ink strokes from a file and render them on an **InkCanvas** control.

Download this sample from Save and load ink strokes from an Ink Serialized Format (ISF) file

1. First, we set up the UI.

   The UI includes "Save", "Load", and "Clear" buttons, and the **InkCanvas**.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto"/>
            <RowDefinition Height="*"/>
        </Grid.RowDefinitions>
        <StackPanel x:Name="HeaderPanel" Orientation="Horizontal"
Grid.Row="0">
            <TextBlock x:Name="Header"
                       Text="Basic ink store sample"
                       Style="{ThemeResource HeaderTextBlockStyle}"
                       Margin="10,0,0,0" />
            <Button x:Name="btnSave"
```

```
                    Content="Save"
                    Margin="50,0,10,0"/>
            <Button x:Name="btnLoad"
                    Content="Load"
                    Margin="50,0,10,0"/>
            <Button x:Name="btnClear"
                    Content="Clear"
                    Margin="50,0,10,0"/>
        </StackPanel>
        <Grid Grid.Row="1">
            <InkCanvas x:Name="inkCanvas" />
        </Grid>
    </Grid>
```

2. We then set some basic ink input behaviors.

   The **InkPresenter** is configured to interpret input data from both pen and mouse as ink strokes (**InputDeviceTypes**), and listeners for the click events on the buttons are declared.

C#

```
public MainPage()
    {
        this.InitializeComponent();

        // Set supported inking device types.
        inkCanvas.InkPresenter.InputDeviceTypes =
            Windows.UI.Core.CoreInputDeviceTypes.Mouse |
            Windows.UI.Core.CoreInputDeviceTypes.Pen;

        // Listen for button click to initiate save.
        btnSave.Click += btnSave_Click;
        // Listen for button click to initiate load.
        btnLoad.Click += btnLoad_Click;
        // Listen for button click to clear ink canvas.
        btnClear.Click += btnClear_Click;
    }
```

3. Finally, we load the ink in the click event handler of the **Load** button.

   A **FileOpenPicker** lets the user select both the file and the location from where to retrieve the saved ink data.

   Once a file is selected, we open an **IRandomAccessStream** stream set to **Read**.

   We then call **LoadAsync** to read, de-serialize, and load the saved ink strokes into the **InkStrokeContainer**. Loading the strokes into the **InkStrokeContainer** causes the **InkPresenter** to immediately render them to the **InkCanvas**.

> **Note**
>
> All existing strokes in the InkStrokeContainer are cleared before new strokes are loaded.

C#

```
// Load ink data from a file.
private async void btnLoad_Click(object sender, RoutedEventArgs e)
{
    // Let users choose their ink file using a file picker.
    // Initialize the picker.
    Windows.Storage.Pickers.FileOpenPicker openPicker =
        new Windows.Storage.Pickers.FileOpenPicker();
    openPicker.SuggestedStartLocation =
        Windows.Storage.Pickers.PickerLocationId.DocumentsLibrary;
    openPicker.FileTypeFilter.Add(".gif");
    // Show the file picker.
    Windows.Storage.StorageFile file = await
openPicker.PickSingleFileAsync();
    // User selects a file and picker returns a reference to the selected
file.
    if (file != null)
    {
        // Open a file stream for reading.
        IRandomAccessStream stream = await
file.OpenAsync(Windows.Storage.FileAccessMode.Read);
        // Read from file.
        using (var inputStream = stream.GetInputStreamAt(0))
        {
            await
inkCanvas.InkPresenter.StrokeContainer.LoadAsync(inputStream);
        }
        stream.Dispose();
    }
    // User selects Cancel and picker returns null.
    else
    {
        // Operation cancelled.
    }
}
```

> **Note**
>
> GIF is the only file format supported for saving ink data. However, the **LoadAsync** method does support the following formats for backward compatibility.

Format	Description

Format	Description
InkSerializedFormat	Specifies ink that is persisted using ISF. This is the most compact persistent representation of ink. It can be embedded within a binary document format or placed directly on the Clipboard.
Base64InkSerializedFormat	Specifies ink that is persisted by encoding the ISF as a base64 stream. This format is provided so ink can be encoded directly in an XML or HTML file.
Gif	Specifies ink that is persisted by using a GIF file that contains ISF as metadata embedded within the file. This enables ink to be viewed in applications that are not ink-enabled and maintain its full ink fidelity when it returns to an ink-enabled application. This format is ideal when transporting ink content within an HTML file and for making it usable by ink and non-ink applications.
Base64Gif	Specifies ink that is persisted by using a base64-encoded fortified GIF. This format is provided when ink is to be encoded directly in an XML or HTML file for later conversion into an image. A possible use of this is in an XML format generated to contain all ink information and used to generate HTML through Extensible Stylesheet Language Transformations (XSLT).

Copy and paste ink strokes with the clipboard

Here, we demonstrate how to use the clipboard to transfer ink strokes between apps.

To support clipboard functionality, the built-in **InkStrokeContainer** cut and copy commands require one or more ink strokes be selected.

For this example, we enable stroke selection when input is modified with a pen barrel button (or right mouse button). For a complete example of how to implement stroke selection, see Pass-through input for advanced processing in Pen and stylus interactions.

Download this sample from Save and load ink strokes from the clipboard

1. First, we set up the UI.

   The UI includes "Cut", "Copy", "Paste", and "Clear" buttons, along with the **InkCanvas** and a selection canvas.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto"/>
            <RowDefinition Height="*"/>
```

```
        </Grid.RowDefinitions>
        <StackPanel x:Name="HeaderPanel" Orientation="Horizontal"
Grid.Row="0">
            <TextBlock x:Name="tbHeader"
                       Text="Basic ink store sample"
                       Style="{ThemeResource HeaderTextBlockStyle}"
                       Margin="10,0,0,0" />
            <Button x:Name="btnCut"
                    Content="Cut"
                    Margin="20,0,10,0"/>
            <Button x:Name="btnCopy"
                    Content="Copy"
                    Margin="20,0,10,0"/>
            <Button x:Name="btnPaste"
                    Content="Paste"
                    Margin="20,0,10,0"/>
            <Button x:Name="btnClear"
                    Content="Clear"
                    Margin="20,0,10,0"/>
        </StackPanel>
        <Grid x:Name="gridCanvas" Grid.Row="1">
            <!-- Canvas for displaying selection UI. -->
            <Canvas x:Name="selectionCanvas"/>
            <!-- Inking area -->
            <InkCanvas x:Name="inkCanvas"/>
        </Grid>
    </Grid>
```

2. We then set some basic ink input behaviors.

   The **InkPresenter** is configured to interpret input data from both pen and mouse as ink strokes (**InputDeviceTypes**). Listeners for the click events on the buttons as well as pointer and stroke events for selection functionality are also declared here.

   For a complete example of how to implement stroke selection, see Pass-through input for advanced processing in Pen and stylus interactions.

C#

```
public MainPage()
    {
        this.InitializeComponent();

        // Set supported inking device types.
        inkCanvas.InkPresenter.InputDeviceTypes =
            Windows.UI.Core.CoreInputDeviceTypes.Mouse |
            Windows.UI.Core.CoreInputDeviceTypes.Pen;

        // Listen for button click to cut ink strokes.
        btnCut.Click += btnCut_Click;
        // Listen for button click to copy ink strokes.
        btnCopy.Click += btnCopy_Click;
```

```
        // Listen for button click to paste ink strokes.
        btnPaste.Click += btnPaste_Click;
        // Listen for button click to clear ink canvas.
        btnClear.Click += btnClear_Click;

        // By default, the InkPresenter processes input modified by
        // a secondary affordance (pen barrel button, right mouse
        // button, or similar) as ink.
        // To pass through modified input to the app for custom processing
        // on the app UI thread instead of the background ink thread, set
        // InputProcessingConfiguration.RightDragAction to LeaveUnprocessed.
        inkCanvas.InkPresenter.InputProcessingConfiguration.RightDragAction
=
            InkInputRightDragAction.LeaveUnprocessed;

        // Listen for unprocessed pointer events from modified input.
        // The input is used to provide selection functionality.
        inkCanvas.InkPresenter.UnprocessedInput.PointerPressed +=
            UnprocessedInput_PointerPressed;
        inkCanvas.InkPresenter.UnprocessedInput.PointerMoved +=
            UnprocessedInput_PointerMoved;
        inkCanvas.InkPresenter.UnprocessedInput.PointerReleased +=
            UnprocessedInput_PointerReleased;

        // Listen for new ink or erase strokes to clean up selection UI.
        inkCanvas.InkPresenter.StrokeInput.StrokeStarted +=
            StrokeInput_StrokeStarted;
        inkCanvas.InkPresenter.StrokesErased +=
            InkPresenter_StrokesErased;
    }
```

3. Finally, after adding stroke selection support, we implement clipboard functionality in the click event handlers of the **Cut**, **Copy**, and **Paste** buttons.

   For cut, we first call **CopySelectedToClipboard** on the **InkStrokeContainer** of the **InkPresenter**.

   We then call **DeleteSelected** to remove the strokes from the ink canvas.

   Finally, we delete all selection strokes from the selection canvas.

C#

```
private void btnCut_Click(object sender, RoutedEventArgs e)
    {
        inkCanvas.InkPresenter.StrokeContainer.CopySelectedToClipboard();
        inkCanvas.InkPresenter.StrokeContainer.DeleteSelected();
        ClearSelection();
    }
```

C#

```
// Clean up selection UI.
    private void ClearSelection()
    {
        var strokes = inkCanvas.InkPresenter.StrokeContainer.GetStrokes();
        foreach (var stroke in strokes)
        {
            stroke.Selected = false;
        }
        ClearDrawnBoundingRect();
    }

    private void ClearDrawnBoundingRect()
    {
        if (selectionCanvas.Children.Any())
        {
            selectionCanvas.Children.Clear();
            boundingRect = Rect.Empty;
        }
    }
```

For copy, we simply call **CopySelectedToClipboard** on the **InkStrokeContainer** of the **InkPresenter**.

C#

```
private void btnCopy_Click(object sender, RoutedEventArgs e)
    {
        inkCanvas.InkPresenter.StrokeContainer.CopySelectedToClipboard();
    }
```

For paste, we call **CanPasteFromClipboard** to ensure that the content on the clipboard can be pasted to the ink canvas.

If so, we call **PasteFromClipboard** to insert the clipboard ink strokes into the **InkStrokeContainer** of the **InkPresenter**, which then renders the strokes to the ink canvas.

C#

```
private void btnPaste_Click(object sender, RoutedEventArgs e)
    {
        if (inkCanvas.InkPresenter.StrokeContainer.CanPasteFromClipboard())
        {
            inkCanvas.InkPresenter.StrokeContainer.PasteFromClipboard(
                new Point(0, 0));
        }
        else
        {
            // Cannot paste from clipboard.
```

```
        }
    }
```

Add an InkToolbar to a Windows app

Article • 05/26/2022

There are two different controls that facilitate inking in Windows apps: **InkCanvas** and **InkToolbar**.

The **InkCanvas** control provides basic Windows Ink functionality. Use it to render pen input as either an ink stroke (using default settings for color and thickness) or an erase stroke.

> For InkCanvas implementation details, see Pen and stylus interactions in Windows apps.

As a completely transparent overlay, the InkCanvas does not provide any built-in UI for setting ink stroke properties. If you want to change the default inking experience, let users set ink stroke properties, and support other custom inking features, you have two options:

- In code-behind, use the underlying **InkPresenter** object bound to the InkCanvas.

  The InkPresenter APIs support extensive customization of the inking experience. For more detail, see Pen and stylus interactions in Windows apps.

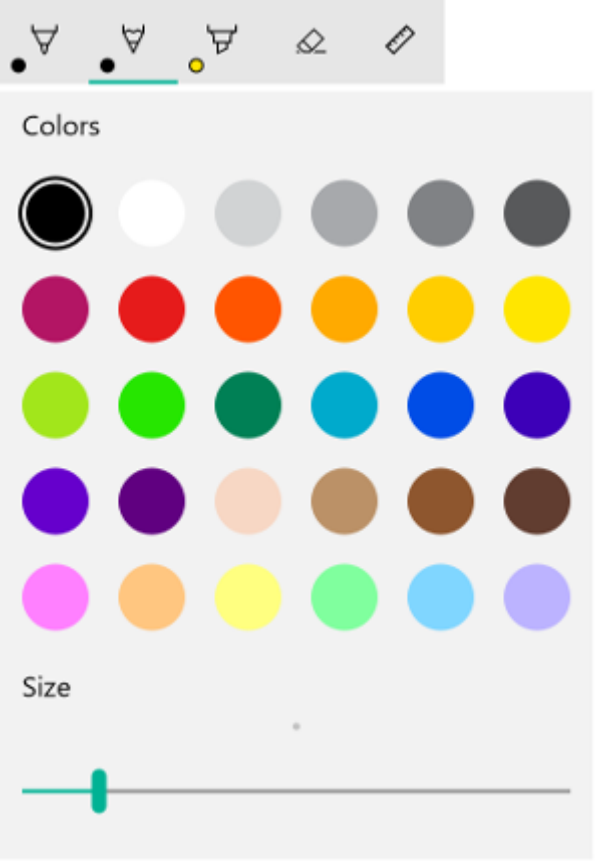
- Bind an **InkToolbar** to the InkCanvas. By default, the InkToolbar provides a customizable and extensible collection of buttons for activating ink-related features such as stroke size, ink color, and pen tip.

  We discuss the InkToolbar in this topic.

> **Important APIs**: **InkCanvas class**, **InkToolbar class**, **InkPresenter class**, **Windows.UI.Input.Inking**

Default InkToolbar

By default, the **InkToolbar** includes buttons for drawing, erasing, highlighting, and displaying a stencil (ruler or protractor). Depending on the feature, other settings and commands, such as ink color, stroke thickness, erase all ink, are provided in a flyout.



Default Windows Ink toolbar

To add a default **InkToolbar** to an inking app, just place it on the same page as your **InkCanvas** and associate the two controls.

1. In MainPage.xaml, declare a container object (for this example, we use a Grid control) for the inking surface.
2. Declare an InkCanvas object as a child of the container. (The InkCanvas size is inherited from the container.)
3. Declare an InkToolbar and use the TargetInkCanvas attribute to bind it to the InkCanvas.

> **Note**
>
> Ensure the InkToolbar is declared after the InkCanvas. If not, the InkCanvas overlay renders the InkToolbar inaccessible.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel x:Name="HeaderPanel" Orientation="Horizontal" Grid.Row="0">
        <TextBlock x:Name="Header"
```

```
                    Text="Basic ink sample"
                    Style="{ThemeResource HeaderTextBlockStyle}"
                    Margin="10,0,0,0" />
    </StackPanel>
    <Grid Grid.Row="1">
        <Image Source="Assets\StoreLogo.png" />
        <InkCanvas x:Name="inkCanvas" />
        <InkToolbar x:Name="inkToolbar"
          VerticalAlignment="Top"
          TargetInkCanvas="{x:Bind inkCanvas}" />
    </Grid>
</Grid>
```

Basic customization

In this section, we cover some basic Windows Ink toolbar customization scenarios.

Specify location and orientation

When you add an ink toolbar to your app, you can accept the default location and orientation of the toolbar or set them as required by your app or user.

XAML

Explicitly specify the location and orientation of the toolbar through its VerticalAlignment, HorizontalAlignment, and Orientation properties.

Expand table

Default	Explicit
Windows Ink toolbar default location and orientation	*Windows Ink toolbar explicit location and orientation*

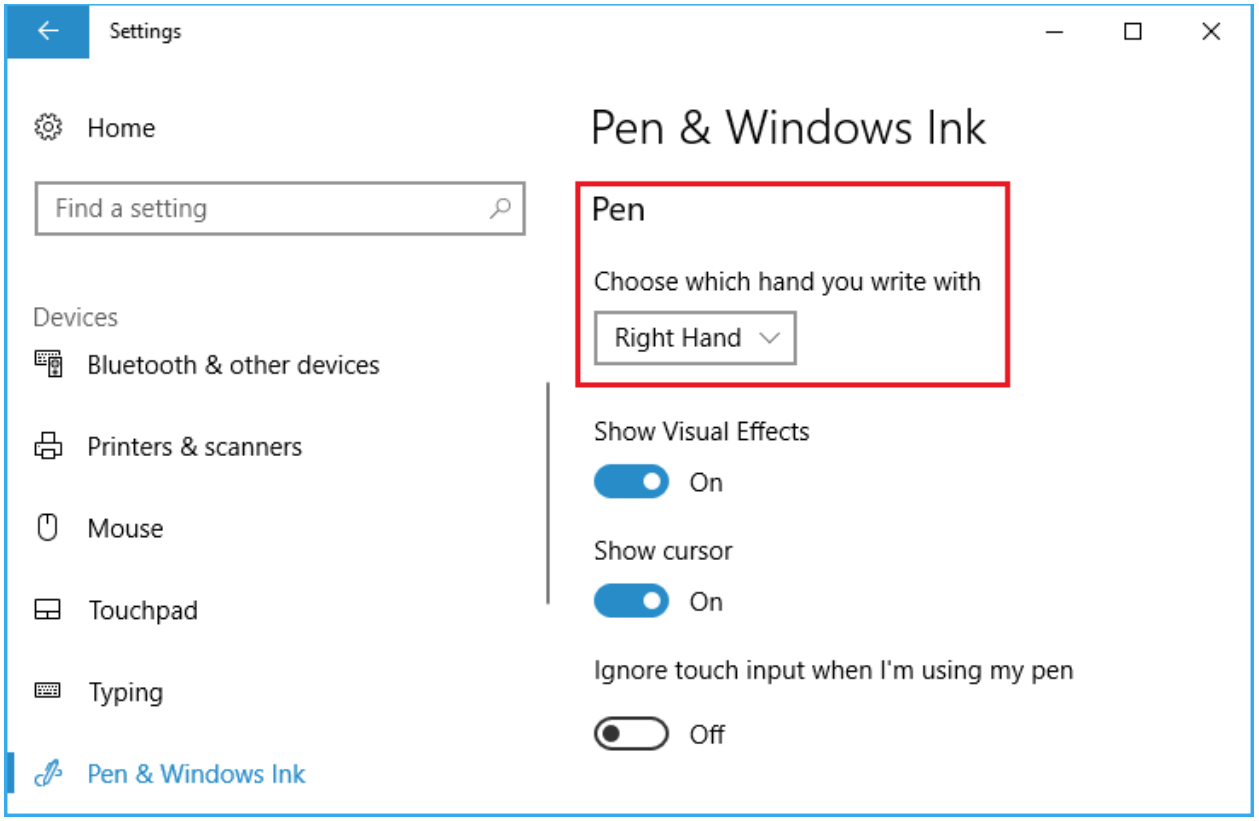
Here's the code for explicitly setting the location and orientation of the ink toolbar in XAML.

XAML

```
<InkToolbar x:Name="inkToolbar"
    VerticalAlignment="Center"
    HorizontalAlignment="Right"
    Orientation="Vertical"
    TargetInkCanvas="{x:Bind inkCanvas}" />
```

Initialize based on user preferences or device state

In some cases, you might want to set the location and orientation of the ink toolbar based on user preference or device state. The following example demonstrates how to set the location and orientation of the ink toolbar based on the left or right-hand writing preferences specified through **Settings** > **Devices** > **Pen & Windows Ink** > **Pen** > **Choose which hand you write with**.



Dominant hand setting

You can query this setting through the HandPreference property of Windows.UI.ViewManagement and set the HorizontalAlignment based on the value returned. In this example, we locate the toolbar on the left side of the app for a left-handed person and on the right side for a right-handed person.

Download this sample from Ink toolbar location and orientation sample (basic)

C#

```
public MainPage()
{
    this.InitializeComponent();

    Windows.UI.ViewManagement.UISettings settings =
        new Windows.UI.ViewManagement.UISettings();
    HorizontalAlignment alignment =
        (settings.HandPreference ==
            Windows.UI.ViewManagement.HandPreference.LeftHanded) ?
            HorizontalAlignment.Left : HorizontalAlignment.Right;
    inkToolbar.HorizontalAlignment = alignment;
}
```

Dynamically adjust to user or device state

You can also use binding to look after UI updates based on changes to user preferences, device settings, or device states. In the following example, we expand on the previous example and show how to dynamically position the ink toolbar based on device orientation using binding, a ViewMOdel object, and the INotifyPropertyChanged interface.

Download this sample from Ink toolbar location and orientation sample (dynamic)

1. First, let's add our ViewModel.

    a. Add a new folder to your project and call it **ViewModels**.

    b. Add a new class to the ViewModels folder (for this example, we called it **InkToolbarSnippetHostViewModel.cs**).

    > **Note**
    >
    > We used the Singleton pattern as we only need one object of this type for the life of the application

    c. Add `using System.ComponentModel` namespace to the file.

    d. Add a static member variable called **instance**, and a static read only property named **Instance**. Make the constructor private to ensure this class can only be accessed via the Instance property.

    > **Note**

This class inherits from INotifyPropertyChanged interface, which is used to notify clients, typically binding clients, that a property value has changed. We'll be using this to handle changes to the device orientation (we'll expand this code and explain further in a later step).

C#

```
using System.ComponentModel;

namespace locationandorientation.ViewModels
{
    public class InkToolbarSnippetHostViewModel :
INotifyPropertyChanged
    {
        private static InkToolbarSnippetHostViewModel instance;

        public static InkToolbarSnippetHostViewModel Instance
        {
            get
            {
                if (null == instance)
                {
                    instance = new InkToolbarSnippetHostViewModel();
                }
                return instance;
            }
        }
    }

    private InkToolbarSnippetHostViewModel() { }
}
```

e. Add two bool properties to the InkToolbarSnippetHostViewModel class: **LeftHandedLayout** (same functionality as the previous XAML-only example) and **PortraitLayout** (orientation of the device).

> ⓘ Note
>
> The PortraitLayout property is settable and includes the definition for the PropertyChanged event.

C#

```
public bool LeftHandedLayout
{
    get
    {
```

```
            bool leftHandedLayout = false;
            Windows.UI.ViewManagement.UISettings settings =
                new Windows.UI.ViewManagement.UISettings();
            leftHandedLayout = (settings.HandPreference ==
                Windows.UI.ViewManagement.HandPreference.LeftHanded);
            return leftHandedLayout;
        }
    }

    public bool portraitLayout = false;
    public bool PortraitLayout
    {
        get
        {
            Windows.UI.ViewManagement.ApplicationViewOrientation
    winOrientation =

    Windows.UI.ViewManagement.ApplicationView.GetForCurrentView().Orient
    ation;
            portraitLayout =
                (winOrientation ==

    Windows.UI.ViewManagement.ApplicationViewOrientation.Portrait);
            return portraitLayout;
        }
        set
        {
            if (value.Equals(portraitLayout)) return;
            portraitLayout = value;
            PropertyChanged?.Invoke(this, new
    PropertyChangedEventArgs("PortraitLayout"));
        }
    }
```

2. Now, let's add a couple of converter classes to our project. Each class contains a Convert object that returns an alignment value (either HorizontalAlignment or VerticalAlignment).

    a. Add a new folder to your project and call it **Converters**.

    b. Add two new classes to the Converters folder (for this example, we call them **HorizontalAlignmentFromHandednessConverter.cs** and **VerticalAlignmentFromAppViewConverter.cs**).

    c. Add `using Windows.UI.Xaml` and `using Windows.UI.Xaml.Data` namespaces to each file.

    d. Change each class to `public` and specify that it implements the IValueConverter interface.

e. Add the Convert and ConvertBack methods to each file, as shown here (we leave the ConvertBack method unimplemented).

- HorizontalAlignmentFromHandednessConverter positions the ink toolbar to the right side of the app for right-handed users and to the left side of the app for left-handed users.

C#

```
using System;

using Windows.UI.Xaml;
using Windows.UI.Xaml.Data;

namespace locationandorientation.Converters
{
    public class HorizontalAlignmentFromHandednessConverter :
IValueConverter
    {
        public object Convert(object value, Type targetType,
            object parameter, string language)
        {
            bool leftHanded = (bool)value;
            HorizontalAlignment alignment =
HorizontalAlignment.Right;
            if (leftHanded)
            {
                alignment = HorizontalAlignment.Left;
            }
            return alignment;
        }

        public object ConvertBack(object value, Type targetType,
            object parameter, string language)
        {
            throw new NotImplementedException();
        }
    }
}
```

- VerticalAlignmentFromAppViewConverter positions the ink toolbar to the center of the app for portrait orientation and to the top of the app for landscape orientation (while intended to improve usability, this is just an arbitrary choice for demonstration purposes).

C#

```
using System;

using Windows.UI.Xaml;
```

```
using Windows.UI.Xaml.Data;

namespace locationandorientation.Converters
{
    public class VerticalAlignmentFromAppViewConverter :
IValueConverter
    {
        public object Convert(object value, Type targetType,
            object parameter, string language)
        {
            bool portraitOrientation = (bool)value;
            VerticalAlignment alignment = VerticalAlignment.Top;
            if (portraitOrientation)
            {
                alignment = VerticalAlignment.Center;
            }
            return alignment;
        }

        public object ConvertBack(object value, Type targetType,
            object parameter, string language)
        {
            throw new NotImplementedException();
        }
    }
}
```

3. Now, open the MainPage.xaml.cs file.
   a. Add `using using locationandorientation.ViewModels` to the list of namespaces to associate our ViewModel.
   b. Add `using Windows.UI.ViewManagement` to the list of namespaces to enable listening for changes to the device orientation.
   c. Add the WindowSizeChangedEventHandler code.
   d. Set the DataContext for the view to the singleton instance of the InkToolbarSnippetHostViewModel class.

C#

```
using Windows.UI.Xaml;
using Windows.UI.Xaml.Controls;

using locationandorientation.ViewModels;
using Windows.UI.ViewManagement;

namespace locationandorientation
{
    public sealed partial class MainPage : Page
    {
        public MainPage()
        {
            this.InitializeComponent();
```

```
            Window.Current.SizeChanged += (sender, args) =>
            {
                ApplicationView currentView =
ApplicationView.GetForCurrentView();

                if (currentView.Orientation ==
ApplicationViewOrientation.Landscape)
                {

InkToolbarSnippetHostViewModel.Instance.PortraitLayout = false;
                }
                else if (currentView.Orientation ==
ApplicationViewOrientation.Portrait)
                {

InkToolbarSnippetHostViewModel.Instance.PortraitLayout = true;
                }
            };

            DataContext = InkToolbarSnippetHostViewModel.Instance;
        }
    }
}
```

4. Next, open the MainPage.xaml file.

    a. Add `xmlns:converters="using:locationandorientation.Converters"` to the `Page` element for binding to our converters.

    XAML

    ```
    <Page
    x:Class="locationandorientation.MainPage"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:local="using:locationandorientation"
    xmlns:converters="using:locationandorientation.Converters"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-
    compatibility/2006"
    mc:Ignorable="d">
    ```

    b. Add a `PageResources` element and specify references to our converters.

    XAML

    ```
    <Page.Resources>
        <converters:HorizontalAlignmentFromHandednessConverter
    x:Key="HorizontalAlignmentConverter"/>
        <converters:VerticalAlignmentFromAppViewConverter
    ```

```
x:Key="VerticalAlignmentConverter"/>
</Page.Resources>
```

c. Add the InkCanvas and InkToolbar elements and bind the VerticalAlignment and HorizontalAlignment properties of the InkToolbar.

XAML

```
<InkCanvas x:Name="inkCanvas" />
<InkToolbar x:Name="inkToolbar"
            VerticalAlignment="{Binding PortraitLayout, Converter=
{StaticResource VerticalAlignmentConverter} }"
            HorizontalAlignment="{Binding LeftHandedLayout,
Converter={StaticResource HorizontalAlignmentConverter} }"
            Orientation="Vertical"
            TargetInkCanvas="{x:Bind inkCanvas}" />
```

5. Return to the InkToolbarSnippetHostViewModel.cs file to add our `PortraitLayout` and `LeftHandedLayout` bool properties to the `InkToolbarSnippetHostViewModel` class, along with support for rebinding `PortraitLayout` when that property value changes.

C#

```
public bool LeftHandedLayout
{
    get
    {
        bool leftHandedLayout = false;
        Windows.UI.ViewManagement.UISettings settings =
            new Windows.UI.ViewManagement.UISettings();
        leftHandedLayout = (settings.HandPreference ==
            Windows.UI.ViewManagement.HandPreference.LeftHanded);
        return leftHandedLayout;
    }
}

public bool portraitLayout = false;
public bool PortraitLayout
{
    get
    {
        Windows.UI.ViewManagement.ApplicationViewOrientation
winOrientation =

Windows.UI.ViewManagement.ApplicationView.GetForCurrentView().Orientati
on;
        portraitLayout =
            (winOrientation ==
```

```
Windows.UI.ViewManagement.ApplicationViewOrientation.Portrait);
        return portraitLayout;
    }
    set
    {
        if (value.Equals(portraitLayout)) return;
        portraitLayout = value;
        PropertyChanged?.Invoke(this, new
PropertyChangedEventArgs("PortraitLayout"));
    }
}

#region INotifyPropertyChanged Members

public event PropertyChangedEventHandler PropertyChanged;

protected void OnPropertyChanged(string property)
{
    PropertyChanged?.Invoke(this, new
PropertyChangedEventArgs(property));
}

#endregion
```

You should now have an inking app that adapts to both the dominant hand preference of the user and dynamically responds to the orientation of the user's device.

Specify the selected button

Windows Ink toolbar with pencil button selected at initialization

By default, the first (or leftmost) button is selected when your app is launched and the toolbar is initialized. In the default Windows Ink toolbar, this is the ballpoint pen button.

Because the framework defines the order of the built-in buttons, the first button might not be the pen or tool you want to activate by default.

You can override this default behavior and specify the selected button on the toolbar.

For this example, we initialize the default toolbar with the pencil button selected and the pencil activated (instead of the ballpoint pen).

1. Use the XAML declaration for the InkCanvas and InkToolbar from the previous example.
2. In code-behind, set up a handler for the Loaded event of the InkToolbar object.

C#

```
/// <summary>
/// An empty page that can be used on its own or navigated to within a
Frame.
/// Here, we set up InkToolbar event listeners.
/// </summary>
public MainPage_CodeBehind()
{
    this.InitializeComponent();
    // Add handlers for InkToolbar events.
    inkToolbar.Loaded += inkToolbar_Loaded;
}
```

3. In the handler for the Loaded event:
   a. Get a reference to the built-in InkToolbarPencilButton.

   Passing an InkToolbarTool.Pencil object in the GetToolButton method returns an InkToolbarToolButton object for the InkToolbarPencilButton.

   b. Set ActiveTool to the object returned in the previous step.

CSharp

```
/// <summary>
/// Handle the Loaded event of the InkToolbar.
/// By default, the active tool is set to the first tool on the toolbar.
/// Here, we set the active tool to the pencil button.
/// </summary>
/// <param name="sender"></param>
/// <param name="e"></param>
private void inkToolbar_Loaded(object sender, RoutedEventArgs e)
{
    InkToolbarToolButton pencilButton =
inkToolbar.GetToolButton(InkToolbarTool.Pencil);
    inkToolbar.ActiveTool = pencilButton;
}
```

Specify the built-in buttons

Specific buttons included at initialization

As mentioned, the Windows Ink toolbar includes a collection of default, built-in buttons. These buttons are displayed in the following order (from left to right):

- InkToolbarBallpointPenButton

- InkToolbarPencilButton
- InkToolbarHighlighterButton
- InkToolbarEraserButton
- InkToolbarRulerButton

For this example, we initialize the toolbar with only the built-in ballpoint pen, pencil, and eraser buttons.

You can do this using either XAML or code-behind.

XAML

Modify the XAML declaration for the InkCanvas and InkToolbar from the first example.

- Add an InitialControls attribute and set its value to "None". This clears the default collection of built-in buttons.
- Add the specific InkToolbar buttons required by your app. Here, we add InkToolbarBallpointPenButton, InkToolbarPencilButton, and InkToolbarEraserButton only.

> **Note**
>
> Buttons are added to the toolbar in the order defined by the framework, not the order specified here.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel x:Name="HeaderPanel" Orientation="Horizontal" Grid.Row="0">
        <TextBlock x:Name="Header"
                   Text="Basic ink sample"
                   Style="{ThemeResource HeaderTextBlockStyle}"
                   Margin="10,0,0,0" />
    </StackPanel>
    <Grid Grid.Row="1">
        <Image Source="Assets\StoreLogo.png" />
        <!-- Clear the default InkToolbar buttons by setting InitialControls
to None. -->
        <!-- Set the active tool to the pencil button. -->
        <InkCanvas x:Name="inkCanvas" />
        <InkToolbar x:Name="inkToolbar"
                    VerticalAlignment="Top"
                    TargetInkCanvas="{x:Bind inkCanvas}"
                    InitialControls="None">
```

```
            <!--
             Add only the ballpoint pen, pencil, and eraser.
             Note that the buttons are added to the toolbar in the order
             defined by the framework, not the order we specify here.
            -->
            <InkToolbarEraserButton />
            <InkToolbarBallpointPenButton />
            <InkToolbarPencilButton/>
        </InkToolbar>
    </Grid>
</Grid>
```

Code-behind

1. Use the XAML declaration for the InkCanvas and InkToolbar from the first example.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel x:Name="HeaderPanel" Orientation="Horizontal" Grid.Row="0">
        <TextBlock x:Name="Header"
                   Text="Basic ink sample"
                   Style="{ThemeResource HeaderTextBlockStyle}"
                   Margin="10,0,0,0" />
    </StackPanel>
    <Grid Grid.Row="1">
        <Image Source="Assets\StoreLogo.png" />
        <InkCanvas x:Name="inkCanvas" />
        <InkToolbar x:Name="inkToolbar"
        VerticalAlignment="Top"
        TargetInkCanvas="{x:Bind inkCanvas}" />
    </Grid>
</Grid>
```

2. In code-behind, set up a handler for the Loading event of the InkToolbar object.

C#

```
/// <summary>
/// An empty page that can be used on its own or navigated to within a
Frame.
/// Here, we set up InkToolbar event listeners.
/// </summary>
public MainPage_CodeBehind()
{
    this.InitializeComponent();
    // Add handlers for InkToolbar events.
```

```
    inkToolbar.Loading += inkToolbar_Loading;
}
```

3. Set InitialControls to "None".
4. Create object references for the buttons required by your app. Here, we add InkToolbarBallpointPenButton, InkToolbarPencilButton, and InkToolbarEraserButton only.

> **Note**
>
> Buttons are added to the toolbar in the order defined by the framework, not the order specified here.

5. Add the buttons to the InkToolbar.

C#

```
/// <summary>
/// Handles the Loading event of the InkToolbar.
/// Here, we identify the buttons to include on the InkToolbar.
/// </summary>
/// <param name="sender">The InkToolbar</param>
/// <param name="args">The InkToolbar event data.
/// If there is no event data, this parameter is null</param>
private void inkToolbar_Loading(FrameworkElement sender, object args)
{
    // Clear all built-in buttons from the InkToolbar.
    inkToolbar.InitialControls = InkToolbarInitialControls.None;

    // Add only the ballpoint pen, pencil, and eraser.
    // Note that the buttons are added to the toolbar in the order
    // defined by the framework, not the order we specify here.
    InkToolbarBallpointPenButton ballpoint = new
InkToolbarBallpointPenButton();
    InkToolbarPencilButton pencil = new InkToolbarPencilButton();
    InkToolbarEraserButton eraser = new InkToolbarEraserButton();
    inkToolbar.Children.Add(eraser);
    inkToolbar.Children.Add(ballpoint);
    inkToolbar.Children.Add(pencil);
}
```

Custom buttons and inking features

You can customize and extend the collection of buttons (and associated inking features) that are provided through the InkToolbar.

The InkToolbar consists of two distinct groups of button types:

1. A group of "tool" buttons containing the built-in drawing, erasing, and highlighting buttons. Custom pens and tools are added here.

> **Note** Feature selection is mutually exclusive.

2. A group of "toggle" buttons containing the built-in ruler button. Custom toggles are added here.

> **Note** Features are not mutually exclusive and can be used concurrently with other active tools.

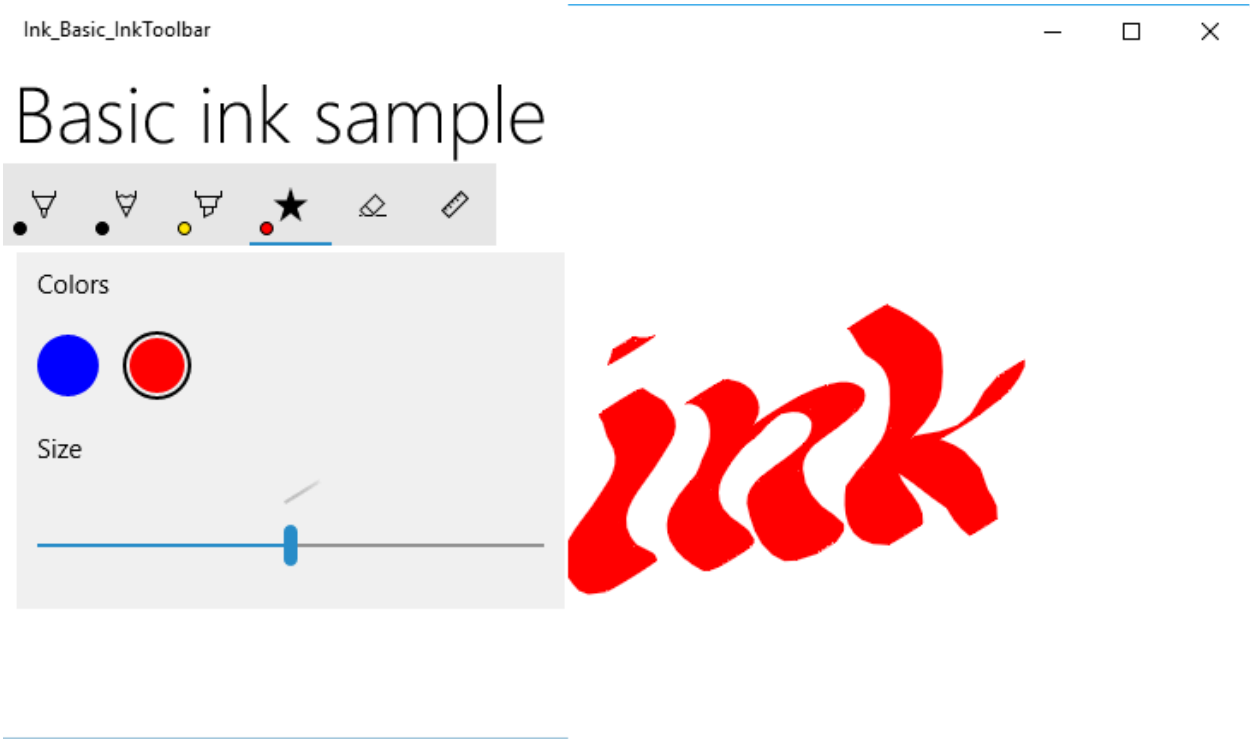
Depending on your application and the inking functionality required, you can add any of the following buttons (bound to your custom ink features) to the InkToolbar:

- Custom pen – a pen for which the ink color palette and pen tip properties, such as shape, rotation, and size, are defined by the host app.
- Custom tool – a non-pen tool, defined by the host app.
- Custom toggle – Sets the state of an app-defined feature to on or off. When turned on, the feature works in conjunction with the active tool.

> **Note** You cannot change the display order of the built-in buttons. The default display order is: Ballpoint pen, pencil, highlighter, eraser, and ruler. Custom pens are appended to the last default pen, custom tool buttons are added between the last pen button and the eraser button and custom toggle buttons are added after the ruler button. (Custom buttons are added in the order they are specified.)

Custom pen

You can create a custom pen (activated through a custom pen button) where you define the ink color palette and pen tip properties, such as shape, rotation, and size.



Custom calligraphic pen button

For this example, we define a custom pen with a broad tip that enables basic calligraphic ink strokes. We also customize the collection of brushes in the palette displayed on the button flyout.

Code-behind

First, we define our custom pen and specify the drawing attributes in code-behind. We reference this custom pen from XAML later.

1. Right click the project in Solution Explorer and select Add -> New item.
2. Under Visual C# -> Code, add a new Class file and call it CalligraphicPen.cs.
3. In Calligraphic.cs, replace the default using block with the following:

```
C#

using System.Numerics;
using Windows.UI;
using Windows.UI.Input.Inking;
using Windows.UI.Xaml.Controls;
using Windows.UI.Xaml.Media;
```

4. Specify that the CalligraphicPen class is derived from InkToolbarCustomPen.

```
C#

class CalligraphicPen : InkToolbarCustomPen
{
```

```
}
```

5. Override CreateInkDrawingAttributesCore to specify your own brush and stroke size.

C#

```
class CalligraphicPen : InkToolbarCustomPen
{
    protected override InkDrawingAttributes
      CreateInkDrawingAttributesCore(Brush brush, double strokeWidth)
    {
    }
}
```

6. Create an InkDrawingAttributes object and set the pen tip shape, tip rotation, stroke size, and ink color.

C#

```
class CalligraphicPen : InkToolbarCustomPen
{
    protected override InkDrawingAttributes
      CreateInkDrawingAttributesCore(Brush brush, double strokeWidth)
    {
        InkDrawingAttributes inkDrawingAttributes =
          new InkDrawingAttributes();
        inkDrawingAttributes.PenTip = PenTipShape.Circle;
        inkDrawingAttributes.Size =
          new Windows.Foundation.Size(strokeWidth, strokeWidth * 20);
        SolidColorBrush solidColorBrush = brush as SolidColorBrush;
        if (solidColorBrush != null)
        {
            inkDrawingAttributes.Color = solidColorBrush.Color;
        }
        else
        {
            inkDrawingAttributes.Color = Colors.Black;
        }

        Matrix3x2 matrix = Matrix3x2.CreateRotation(45);
        inkDrawingAttributes.PenTipTransform = matrix;

        return inkDrawingAttributes;
    }
}
```

XAML

Next, we add the necessary references to the custom pen in MainPage.xaml.

1. We declare a local page resource dictionary that creates a reference to the custom pen (`CalligraphicPen`) defined in CalligraphicPen.cs, and a brush collection supported by the custom pen (`CalligraphicPenPalette`).

XAML

```
<Page.Resources>
    <!-- Add the custom CalligraphicPen to the page resources. -->
    <local:CalligraphicPen x:Key="CalligraphicPen" />
    <!-- Specify the colors for the palette of the custom pen. -->
    <BrushCollection x:Key="CalligraphicPenPalette">
        <SolidColorBrush Color="Blue" />
        <SolidColorBrush Color="Red" />
    </BrushCollection>
</Page.Resources>
```

2. We then add an InkToolbar with a child InkToolbarCustomPenButton element.

The custom pen button includes the two static resource references declared in the page resources: `CalligraphicPen` and `CalligraphicPenPalette`.

We also specify the range for the stroke size slider (MinStrokeWidth, MaxStrokeWidth, and SelectedStrokeWidth), the selected brush (SelectedBrushIndex), and the icon for the custom pen button (SymbolIcon).

XAML

```
<Grid Grid.Row="1">
    <InkCanvas x:Name="inkCanvas" />
    <InkToolbar x:Name="inkToolbar"
                VerticalAlignment="Top"
                TargetInkCanvas="{x:Bind inkCanvas}">
        <InkToolbarCustomPenButton
            CustomPen="{StaticResource CalligraphicPen}"
            Palette="{StaticResource CalligraphicPenPalette}"
            MinStrokeWidth="1" MaxStrokeWidth="3" SelectedStrokeWidth="2"
            SelectedBrushIndex ="1">
            <SymbolIcon Symbol="Favorite" />
            <InkToolbarCustomPenButton.ConfigurationContent>
                <InkToolbarPenConfigurationControl />
            </InkToolbarCustomPenButton.ConfigurationContent>
        </InkToolbarCustomPenButton>
    </InkToolbar>
</Grid>
```

Custom toggle

You can create a custom toggle (activated through a custom toggle button) to set the state of an app-defined feature to on or off. When turned on, the feature works in conjunction with the active tool.

In this example, we define a custom toggle button that enables inking with touch input (by default, touch inking is not enabled).

> ⓘ **Note**
>
> If you need to support inking with touch, we recommended that you enable it using a CustomToggleButton, with the icon and **tooltip** specified in this example.

Typically, touch input is used for direct manipulation of an object or the app UI. To demonstrate the differences in behavior when touch inking is enabled, we place the InkCanvas within a ScrollViewer container and set the dimensions of the ScrollViewer to be smaller than the InkCanvas.

When the app starts, only pen inking is supported and touch is used to pan or zoom the inking surface. When touch inking is enabled, the inking surface cannot be panned or zoomed through touch input.

> ⓘ **Note**
>
> See **Inking controls** for both **InkCanvas** and **InkToolbar** UX guidelines. The following recommendations are relevant to this example:
>
> - The **InkToolbar**, and inking in general, is best experienced through an active pen. However, inking with mouse and touch can be supported if required by your app.
> - If supporting inking with touch input, we recommend using the "ED5F" icon from the "Segoe MLD2 Assets" font for the toggle button, with a "Touch writing" tooltip.

XAML

1. First, we declare an **InkToolbarCustomToggleButton** element (toggleButton) with a Click event listener that specifies the event handler (Toggle_Custom).

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
```

```
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>

    <StackPanel Grid.Row="0"
                x:Name="HeaderPanel"
                Orientation="Horizontal">
        <TextBlock x:Name="Header"
                   Text="Basic ink sample"
                   Style="{ThemeResource HeaderTextBlockStyle}"
                   Margin="10" />
    </StackPanel>

    <ScrollViewer Grid.Row="1"
                  HorizontalScrollBarVisibility="Auto"
                  VerticalScrollBarVisibility="Auto">

        <Grid HorizontalAlignment="Left" VerticalAlignment="Top">
            <Grid.RowDefinitions>
                <RowDefinition Height="Auto"/>
                <RowDefinition Height="*"/>
            </Grid.RowDefinitions>

            <InkToolbar Grid.Row="0"
                        Margin="10"
                        x:Name="inkToolbar"
                        VerticalAlignment="Top"
                        TargetInkCanvas="{x:Bind inkCanvas}">
                <InkToolbarCustomToggleButton
                x:Name="toggleButton"
                Click="CustomToggle_Click"
                ToolTipService.ToolTip="Touch Writing">
                    <SymbolIcon Symbol="{x:Bind TouchWritingIcon}"/>
                </InkToolbarCustomToggleButton>
            </InkToolbar>

            <ScrollViewer Grid.Row="1"
                          Height="500"
                          Width="500"
                          x:Name="scrollViewer"
                          ZoomMode="Enabled"
                          MinZoomFactor=".1"
                          VerticalScrollMode="Enabled"
                          VerticalScrollBarVisibility="Auto"
                          HorizontalScrollMode="Enabled"
                          HorizontalScrollBarVisibility="Auto">

                <Grid x:Name="outputGrid"
                      Height="1000"
                      Width="1000"
                      Background="{ThemeResource
SystemControlBackgroundChromeWhiteBrush}">
                    <InkCanvas x:Name="inkCanvas"/>
                </Grid>
```

```
            </ScrollViewer>
        </Grid>
    </ScrollViewer>
</Grid>
```

Code-behind

2. In the previous snippet, we declared a Click event listener and handler (Toggle_Custom) on the custom toggle button for touch inking (toggleButton). This handler simply toggles support for CoreInputDeviceTypes.Touch through the InputDeviceTypes property of the InkPresenter.

   We also specified an icon for the button using the SymbolIcon element and the {x:Bind} markup extension that binds it to a field defined in the code-behind file (TouchWritingIcon).

   The following snippet includes both the Click event handler and the definition of TouchWritingIcon.

C#

```
namespace Ink_Basic_InkToolbar
{
    /// <summary>
    /// An empty page that can be used on its own or navigated to within a
Frame.
    /// </summary>
    public sealed partial class MainPage_AddCustomToggle : Page
    {
        Symbol TouchWritingIcon = (Symbol)0xED5F;

        public MainPage_AddCustomToggle()
        {
            this.InitializeComponent();
        }

        // Handler for the custom toggle button that enables touch inking.
        private void CustomToggle_Click(object sender, RoutedEventArgs e)
        {
            if (toggleButton.IsChecked == true)
            {
                inkCanvas.InkPresenter.InputDeviceTypes |=
CoreInputDeviceTypes.Touch;
            }
            else
            {
                inkCanvas.InkPresenter.InputDeviceTypes &=
~CoreInputDeviceTypes.Touch;
            }
        }
```

```
    }
}
```

Custom tool

You can create a custom tool button to invoke a non-pen tool that is defined by your app.

By default, an **InkPresenter** processes all input as either an ink stroke or an erase stroke. This includes input modified by a secondary hardware affordance such as a pen barrel button, a right mouse button, or similar. However, **InkPresenter** can be configured to leave specific input unprocessed, which can then be passed through to your app for custom processing.

In this example, we define a custom tool button that, when selected, causes subsequent strokes to be processed and rendered as a selection lasso (dashed line) instead of ink. All ink strokes within the bounds of the selection area are set to **Selected**.

> **Note**
>
> See Inking controls for both InkCanvas and InkToolbar UX guidelines. The following recommendation is relevant to this example:
>
> - If providing stroke selection, we recommend using the "EF20" icon from the "Segoe MLD2 Assets" font for the tool button, with a "Selection tool" tooltip.

XAML

1. First, we declare an **InkToolbarCustomToolButton** element (customToolButton) with a Click event listener that specifies the event handler (customToolButton_Click) where stroke selection is configured. (We've also added a set of buttons for copying, cutting, and pasting the stroke selection.)

2. We also add a Canvas element for drawing our selection stroke. Using a separate layer to draw the selection stroke ensures the **InkCanvas** and its content remain untouched.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="Auto"/>
```

```
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel x:Name="HeaderPanel" Orientation="Horizontal" Grid.Row="0">
        <TextBlock x:Name="Header"
                   Text="Basic ink sample"
                   Style="{ThemeResource HeaderTextBlockStyle}"
                   Margin="10,0,0,0" />
    </StackPanel>
    <StackPanel x:Name="ToolPanel" Orientation="Horizontal" Grid.Row="1">
        <InkToolbar x:Name="inkToolbar"
                    VerticalAlignment="Top"
                    TargetInkCanvas="{x:Bind inkCanvas}">
            <InkToolbarCustomToolButton
                x:Name="customToolButton"
                Click="customToolButton_Click"
                ToolTipService.ToolTip="Selection tool">
                <SymbolIcon Symbol="{x:Bind SelectIcon}"/>
            </InkToolbarCustomToolButton>
        </InkToolbar>
        <Button x:Name="cutButton"
                Content="Cut"
                Click="cutButton_Click"
                Width="100"
                Margin="5,0,0,0"/>
        <Button x:Name="copyButton"
                Content="Copy"
                Click="copyButton_Click"
                Width="100"
                Margin="5,0,0,0"/>
        <Button x:Name="pasteButton"
                Content="Paste"
                Click="pasteButton_Click"
                Width="100"
                Margin="5,0,0,0"/>
    </StackPanel>
    <Grid Grid.Row="2" x:Name="outputGrid"
              Background="{ThemeResource
SystemControlBackgroundChromeWhiteBrush}"
              Height="Auto">
        <!-- Canvas for displaying selection UI. -->
        <Canvas x:Name="selectionCanvas"/>
        <!-- Canvas for displaying ink. -->
        <InkCanvas x:Name="inkCanvas" />
    </Grid>
</Grid>
```

Code-behind

2. We then handle the Click event for the **InkToolbarCustomToolButton** in the MainPage.xaml.cs code-behind file.

   This handler configures the **InkPresenter** to pass unprocessed input through to the app.

For a more detailed step through of this code: See the Pass-through input for advanced processing section of Pen interactions and Windows Ink in Windows apps.

We also specified an icon for the button using the SymbolIcon element and the {x:Bind} markup extension that binds it to a field defined in the code-behind file (SelectIcon).

The following snippet includes both the Click event handler and the definition of SelectIcon.

C#

```
namespace Ink_Basic_InkToolbar
{
    /// <summary>
    /// An empty page that can be used on its own or navigated to within a
Frame.
    /// </summary>
    public sealed partial class MainPage_AddCustomTool : Page
    {
        // Icon for custom selection tool button.
        Symbol SelectIcon = (Symbol)0xEF20;

        // Stroke selection tool.
        private Polyline lasso;
        // Stroke selection area.
        private Rect boundingRect;

        public MainPage_AddCustomTool()
        {
            this.InitializeComponent();

            // Listen for new ink or erase strokes to clean up selection UI.
            inkCanvas.InkPresenter.StrokeInput.StrokeStarted +=
                StrokeInput_StrokeStarted;
            inkCanvas.InkPresenter.StrokesErased +=
                InkPresenter_StrokesErased;
        }

        private void customToolButton_Click(object sender, RoutedEventArgs
e)
        {
            // By default, the InkPresenter processes input modified by
            // a secondary affordance (pen barrel button, right mouse
            // button, or similar) as ink.
            // To pass through modified input to the app for custom
processing
            // on the app UI thread instead of the background ink thread,
set
            // InputProcessingConfiguration.RightDragAction to
LeaveUnprocessed.
```

```
inkCanvas.InkPresenter.InputProcessingConfiguration.RightDragAction =
                InkInputRightDragAction.LeaveUnprocessed;

            // Listen for unprocessed pointer events from modified input.
            // The input is used to provide selection functionality.
            inkCanvas.InkPresenter.UnprocessedInput.PointerPressed +=
                UnprocessedInput_PointerPressed;
            inkCanvas.InkPresenter.UnprocessedInput.PointerMoved +=
                UnprocessedInput_PointerMoved;
            inkCanvas.InkPresenter.UnprocessedInput.PointerReleased +=
                UnprocessedInput_PointerReleased;
        }

        // Handle new ink or erase strokes to clean up selection UI.
        private void StrokeInput_StrokeStarted(
            InkStrokeInput sender, Windows.UI.Core.PointerEventArgs args)
        {
            ClearSelection();
        }

        private void InkPresenter_StrokesErased(
            InkPresenter sender, InkStrokesErasedEventArgs args)
        {
            ClearSelection();
        }

        private void cutButton_Click(object sender, RoutedEventArgs e)
        {

inkCanvas.InkPresenter.StrokeContainer.CopySelectedToClipboard();
            inkCanvas.InkPresenter.StrokeContainer.DeleteSelected();
            ClearSelection();
        }

        private void copyButton_Click(object sender, RoutedEventArgs e)
        {

inkCanvas.InkPresenter.StrokeContainer.CopySelectedToClipboard();
        }

        private void pasteButton_Click(object sender, RoutedEventArgs e)
        {
            if
(inkCanvas.InkPresenter.StrokeContainer.CanPasteFromClipboard())
            {
                inkCanvas.InkPresenter.StrokeContainer.PasteFromClipboard(
                    new Point(0, 0));
            }
            else
            {
                // Cannot paste from clipboard.
            }
        }
```

```
        // Clean up selection UI.
        private void ClearSelection()
        {
            var strokes =
inkCanvas.InkPresenter.StrokeContainer.GetStrokes();
            foreach (var stroke in strokes)
            {
                stroke.Selected = false;
            }
            ClearBoundingRect();
        }

        private void ClearBoundingRect()
        {
            if (selectionCanvas.Children.Any())
            {
                selectionCanvas.Children.Clear();
                boundingRect = Rect.Empty;
            }
        }

        // Handle unprocessed pointer events from modified input.
        // The input is used to provide selection functionality.
        // Selection UI is drawn on a canvas under the InkCanvas.
        private void UnprocessedInput_PointerPressed(
            InkUnprocessedInput sender, PointerEventArgs args)
        {
            // Initialize a selection lasso.
            lasso = new Polyline()
            {
                Stroke = new SolidColorBrush(Windows.UI.Colors.Blue),
                StrokeThickness = 1,
                StrokeDashArray = new DoubleCollection() { 5, 2 },
            };

            lasso.Points.Add(args.CurrentPoint.RawPosition);

            selectionCanvas.Children.Add(lasso);
        }

        private void UnprocessedInput_PointerMoved(
            InkUnprocessedInput sender, PointerEventArgs args)
        {
            // Add a point to the lasso Polyline object.
            lasso.Points.Add(args.CurrentPoint.RawPosition);
        }

        private void UnprocessedInput_PointerReleased(
            InkUnprocessedInput sender, PointerEventArgs args)
        {
            // Add the final point to the Polyline object and
            // select strokes within the lasso area.
            // Draw a bounding box on the selection canvas
            // around the selected ink strokes.
            lasso.Points.Add(args.CurrentPoint.RawPosition);
```

```
            boundingRect =
                inkCanvas.InkPresenter.StrokeContainer.SelectWithPolyLine(
                    lasso.Points);

            DrawBoundingRect();
        }

        // Draw a bounding rectangle, on the selection canvas, encompassing
        // all ink strokes within the lasso area.
        private void DrawBoundingRect()
        {
            // Clear all existing content from the selection canvas.
            selectionCanvas.Children.Clear();

            // Draw a bounding rectangle only if there are ink strokes
            // within the lasso area.
            if (!((boundingRect.Width == 0) ||
                (boundingRect.Height == 0) ||
                boundingRect.IsEmpty))
            {
                var rectangle = new Rectangle()
                {
                    Stroke = new SolidColorBrush(Windows.UI.Colors.Blue),
                    StrokeThickness = 1,
                    StrokeDashArray = new DoubleCollection() { 5, 2 },
                    Width = boundingRect.Width,
                    Height = boundingRect.Height
                };

                Canvas.SetLeft(rectangle, boundingRect.X);
                Canvas.SetTop(rectangle, boundingRect.Y);

                selectionCanvas.Children.Add(rectangle);
            }
        }
    }
}
```

Custom ink rendering

By default, ink input is processed on a low-latency background thread and rendered "wet" as it is drawn. When the stroke is completed (pen or finger lifted, or mouse button released), the stroke is processed on the UI thread and rendered "dry" to the **InkCanvas** layer (above the application content and replacing the wet ink).

The ink platform enables you to override this behavior and completely customize the inking experience by custom drying the ink input.

For more info on custom drying, see Pen interactions and Windows Ink in Windows apps.

> **Note**
>
> Custom drying and the **InkToolbar**
> If your app overrides the default ink rendering behavior of the **InkPresenter** with a custom drying implementation, the rendered ink strokes are no longer available to the InkToolbar and the built-in erase commands of the InkToolbar do not work as expected. To provide erase functionality, you must handle all pointer events, perform hit-testing on each stroke, and override the built-in "Erase all ink" command.

Touch interactions

Article • 01/19/2024

This topic provides design guidelines for building custom, touch-optimized experiences in Windows apps.

Overview

Touch is a primary form of input across Windows and Windows apps that involves the use of one or more fingers (or touch contacts). These touch contacts, and their movement, are interpreted as touch gestures and manipulations that support a variety of user interactions.

Both the Windows SDK and the Windows App SDK include comprehensive collections of touch-optimized controls that provide robust and consistent experiences across Windows apps.

Use these guidelines when creating custom controls, experiences, and frameworks for your Windows apps.

Design principles

Consider the following as you design the touch experience in your Windows app.

Touch Optimized

Windows app experiences should feel inviting to touch, allow for direct manipulation, and accommodate less-precise interactions. Consider touch accelerators including gestures and pen and voice integration.

Consistent Across Postures

Your app should have a consistent experience regardless of the input method or posture the user is in. Changes from traditional desktop posture to tablet posture (see Recommended settings for better tablet experiences), as well as changes in orientation, should not be disorienting, but rather subtle and only as necessary. Your app should reflow UI in subtle ways to create a familiar, cohesive experience that meets users where they are.

Responsive

Apps and interactions should provide users with feedback at every phase (Touch down, action, touch up) of an interaction using animations that respond to a user's existing state while indicating possible actions. Animations should also maintain at least 60 fps to feel smooth and modern.

Honoring Touch Conventions

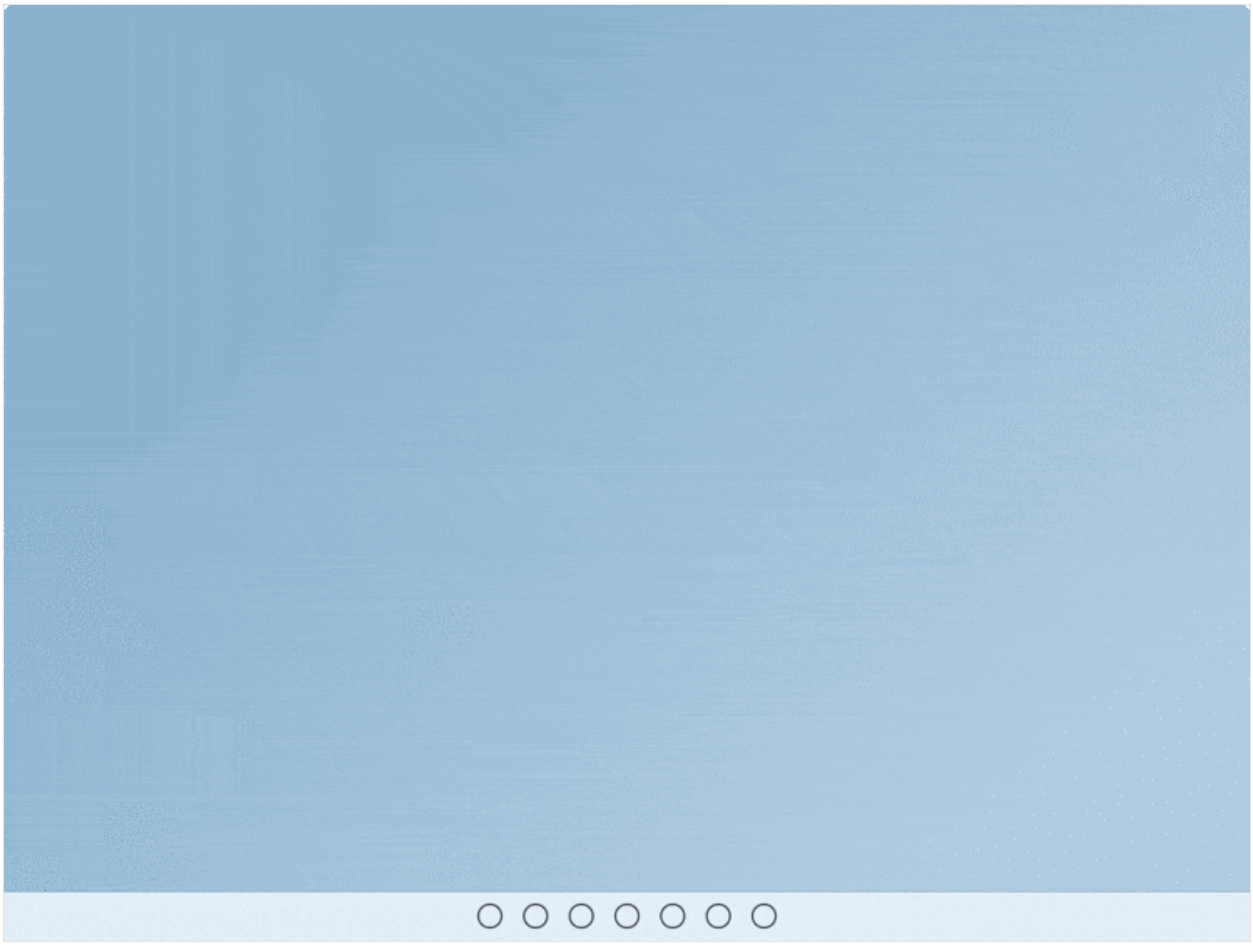
Responsive Feedback

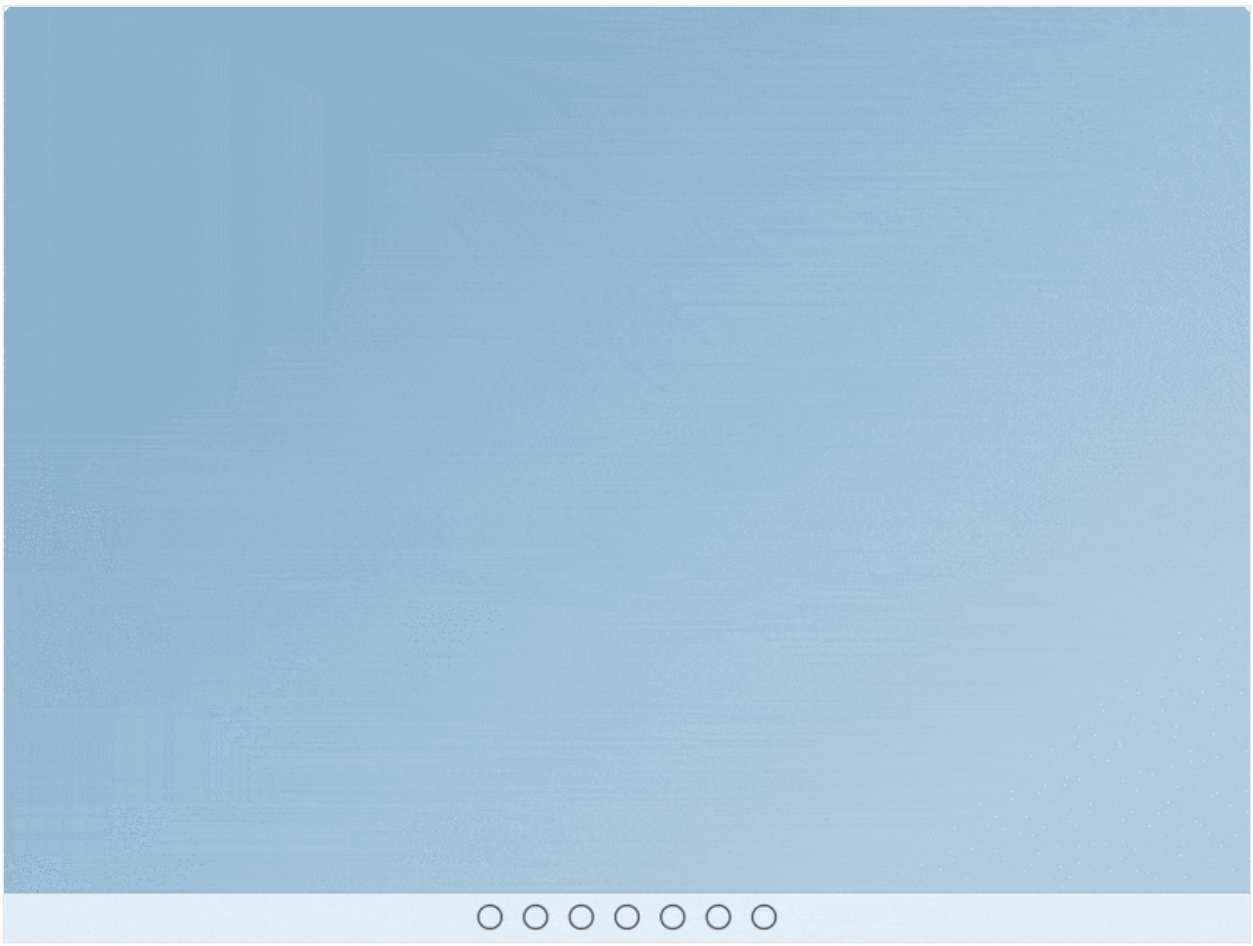
Appropriate visual feedback during interactions with your app helps users recognize, learn, and adapt to how their interactions are interpreted by both the app and the Windows platform. Provide immediate and continuous feedback in response to the user's touch, that is noticeable, comprehensible, and not lost by distractions. This immediate feedback is how users will learn and explore the interactive elements of your app.

- Feedback should be immediate on touch down and moving objects should stick to the user's finger.
- UI should respond to gestures by matching user speed and movements, avoid using keyframe animations.
- Visual feedback should convey possible outcomes before the user commits to an action.

Do

Don't





For more info, see Guidelines for visual feedback and Motion in Windows 11

Touch Interaction Patterns

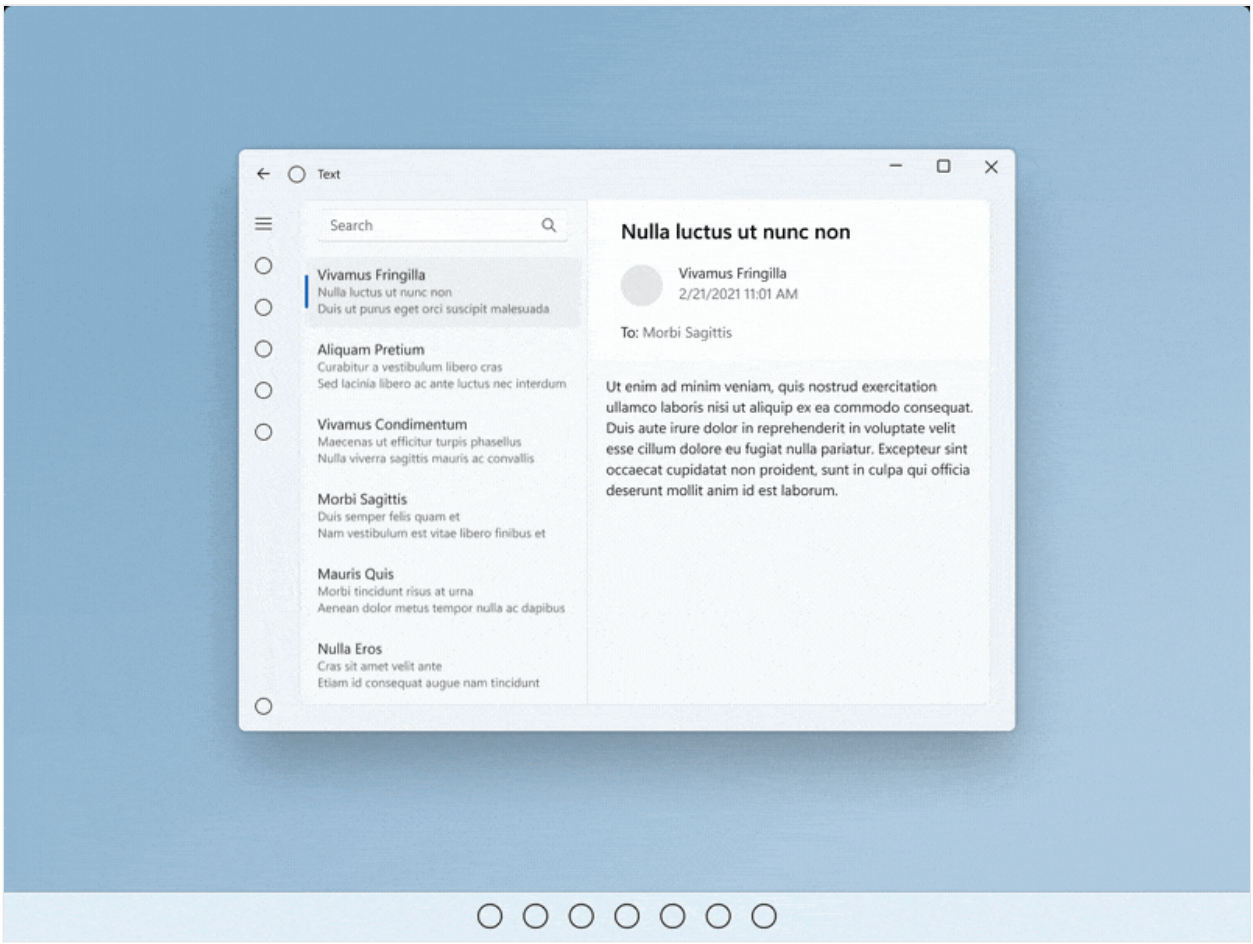
Honor these common interaction and gestures patterns to bring consistency and predictably to your experience.

Common Interactions

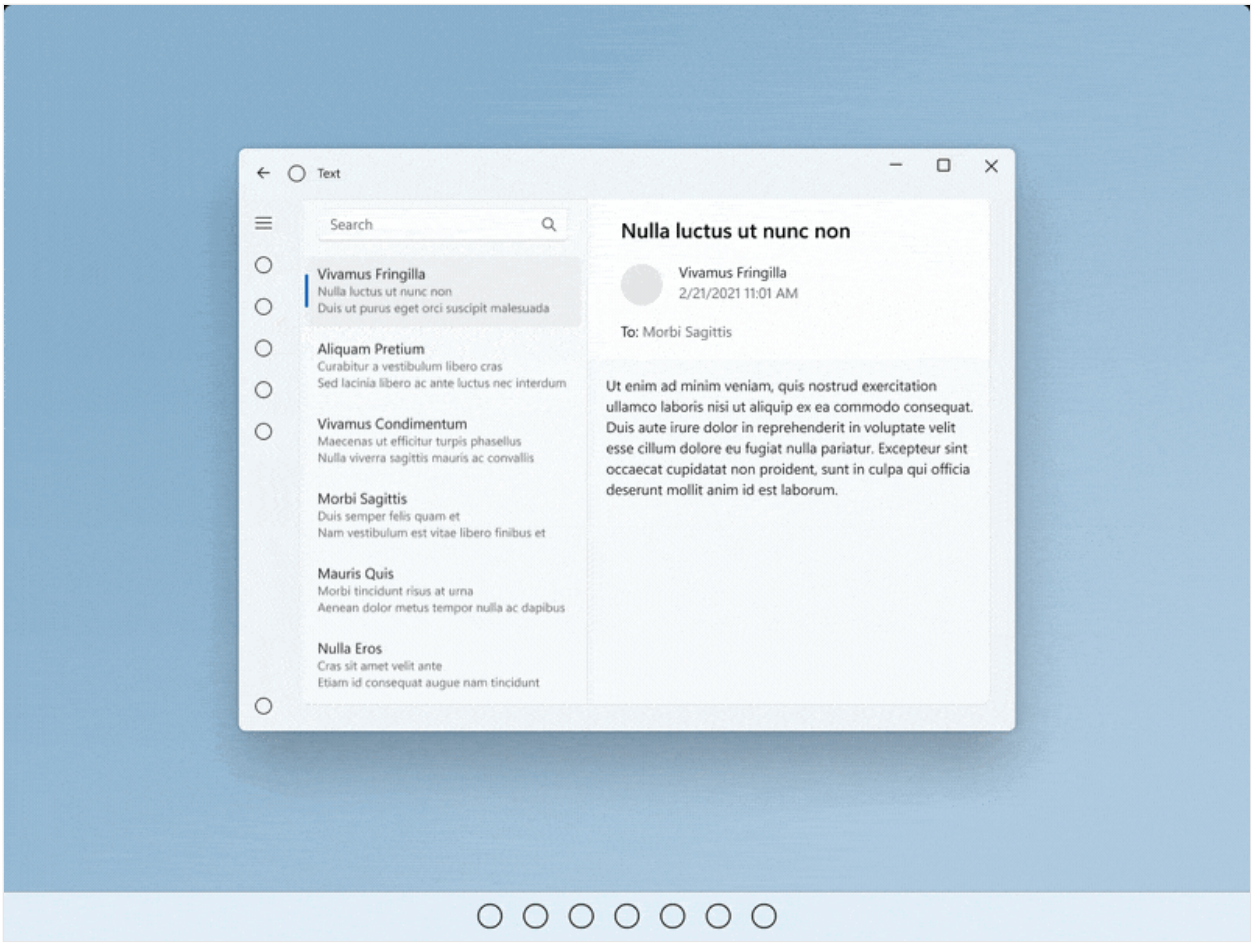
There are a set of common touch behaviors and gestures that users are familiar with and expect to work consistently across all Windows experiences.

- **Tap** to activate or select an item
- **Short press and drag** to move an object
- **Press and hold** to access a menu of secondary, contextual commands
- **Swipe (or drag and release)** for contextual commands
- **Rotate** clockwise or counterclockwise to pivot

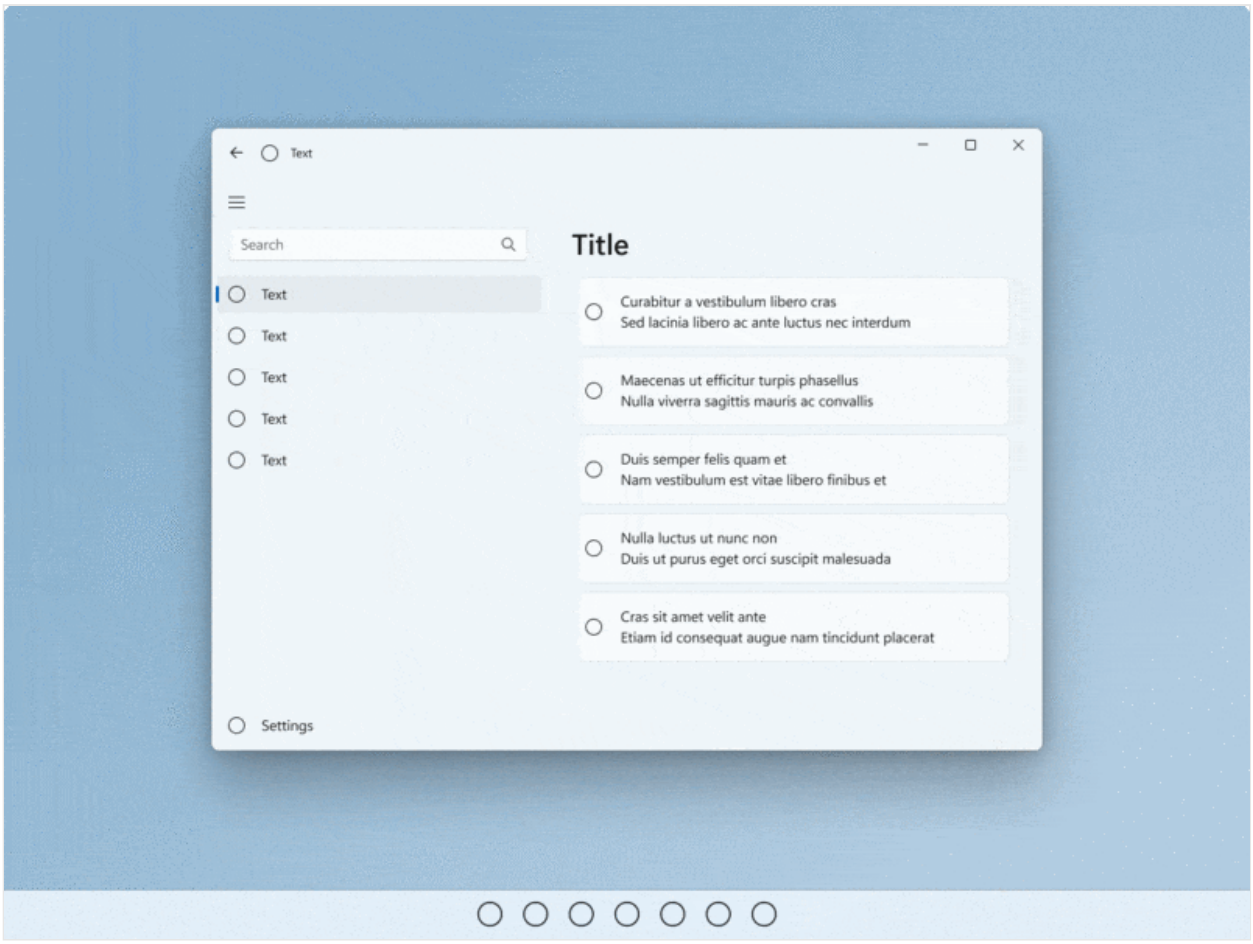
Interactions



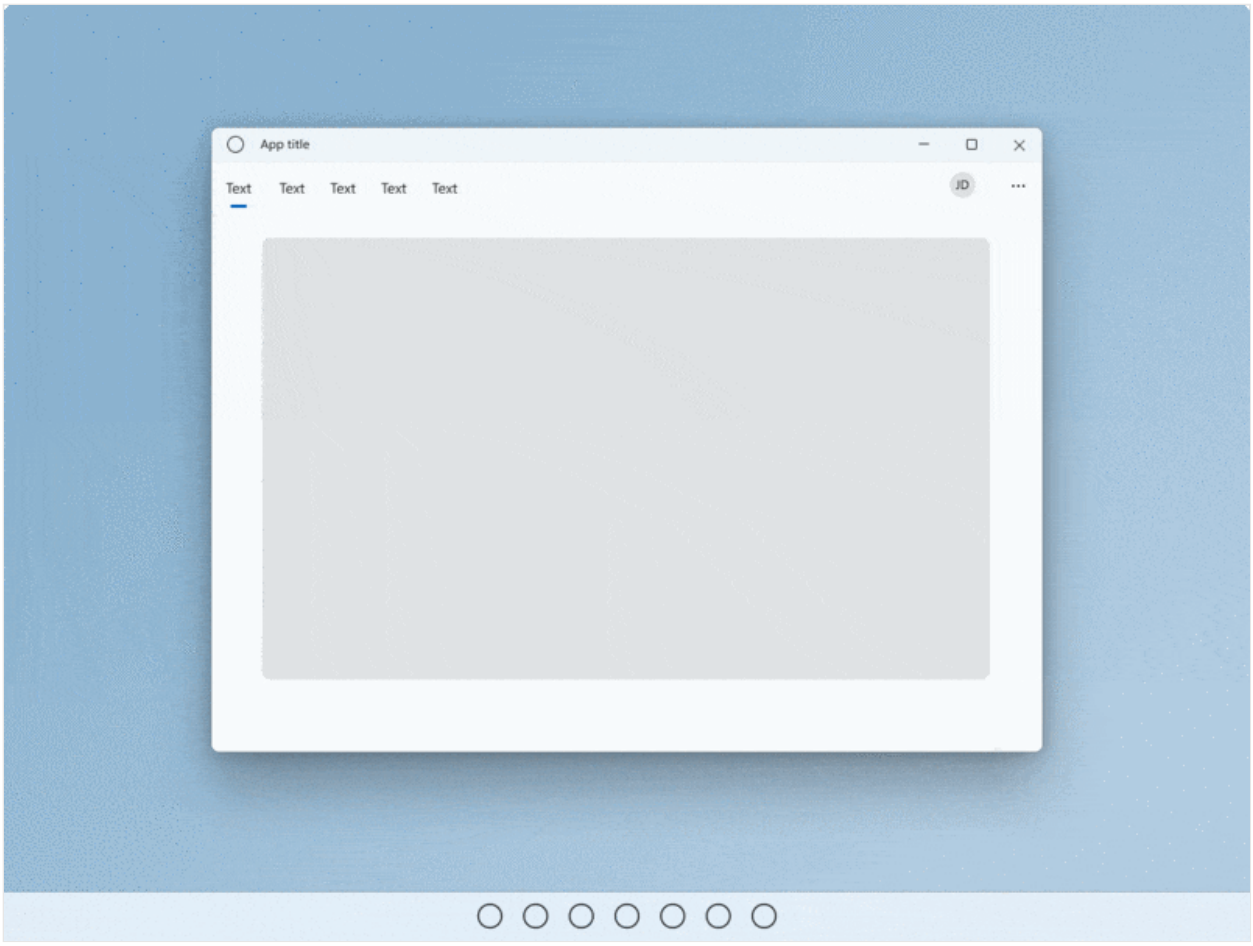
Tap



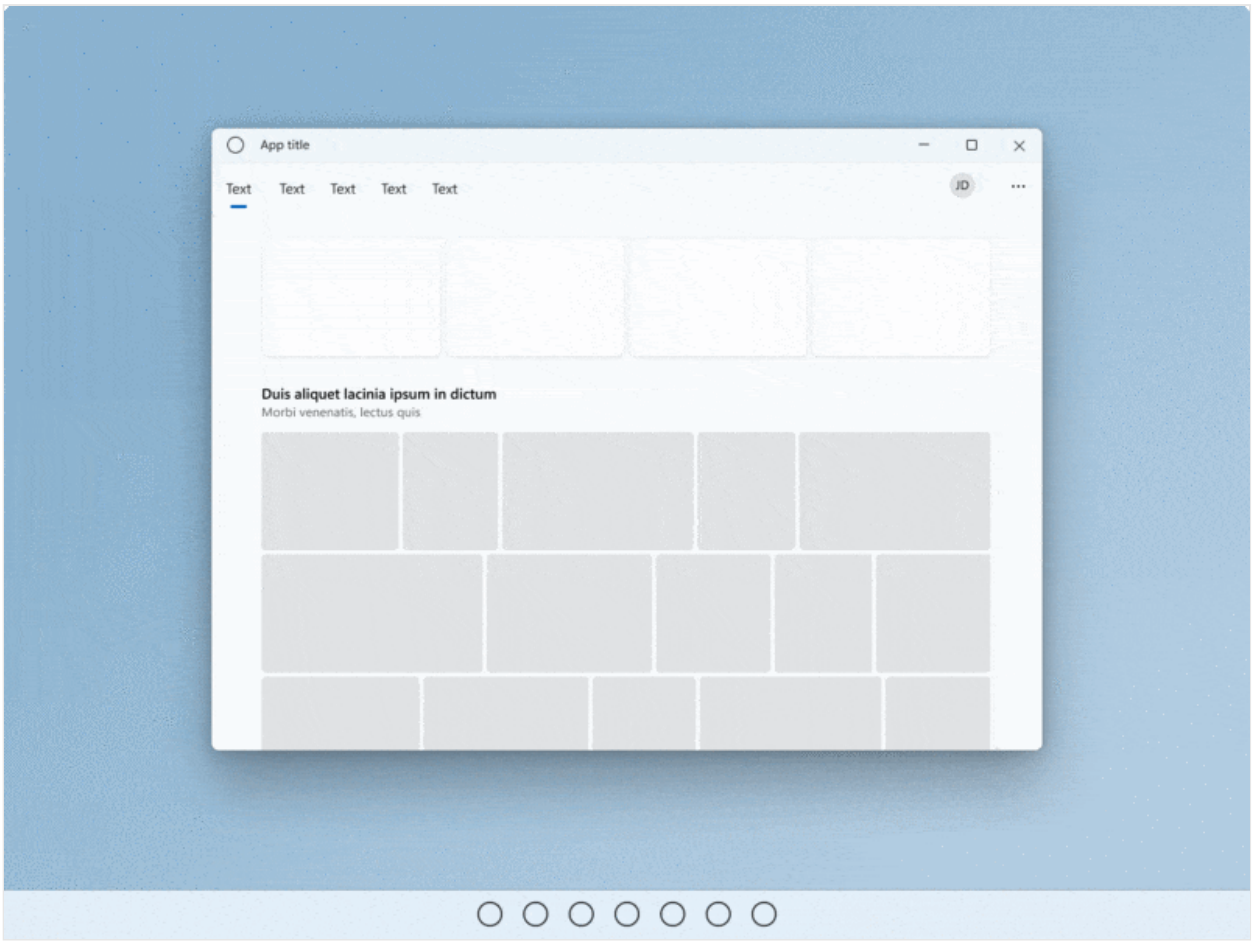
Swipe (or drag and release)



Short press and drag



Rotate



Press and hold

For more info, see Guidelines for visual feedback and Motion in Windows 11

Gestures

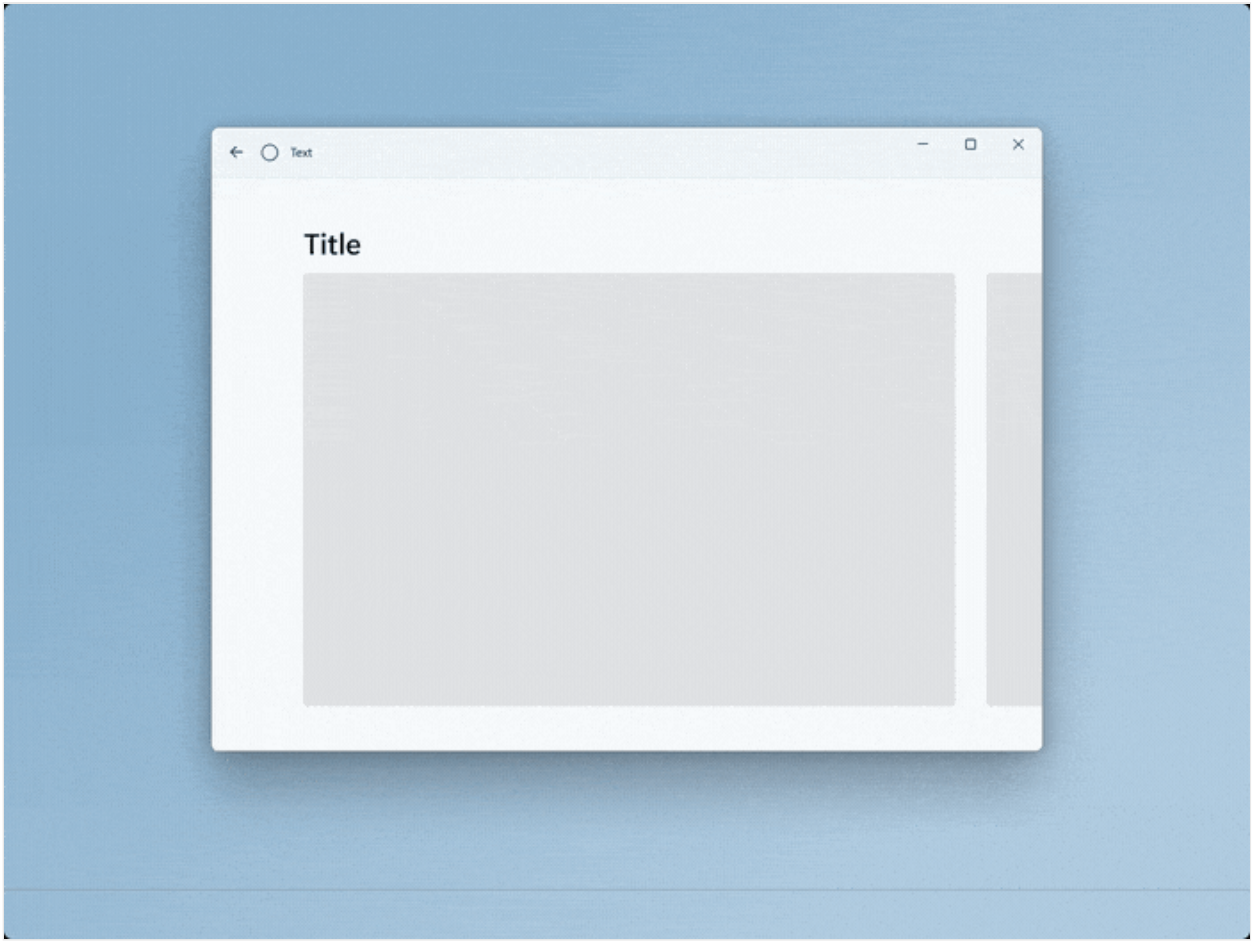
Gestures lower the effort required by users to navigate and act on common interactions. Where possible, support UI with touch gestures to make it easy for users to navigate and act in an app.

If navigating between views, use connected animations so existing and new states are both visible mid-drag. If interacting with UI, items should follow user movement, provide feedback and, on release, react with additional actions based on drag position thresholds.

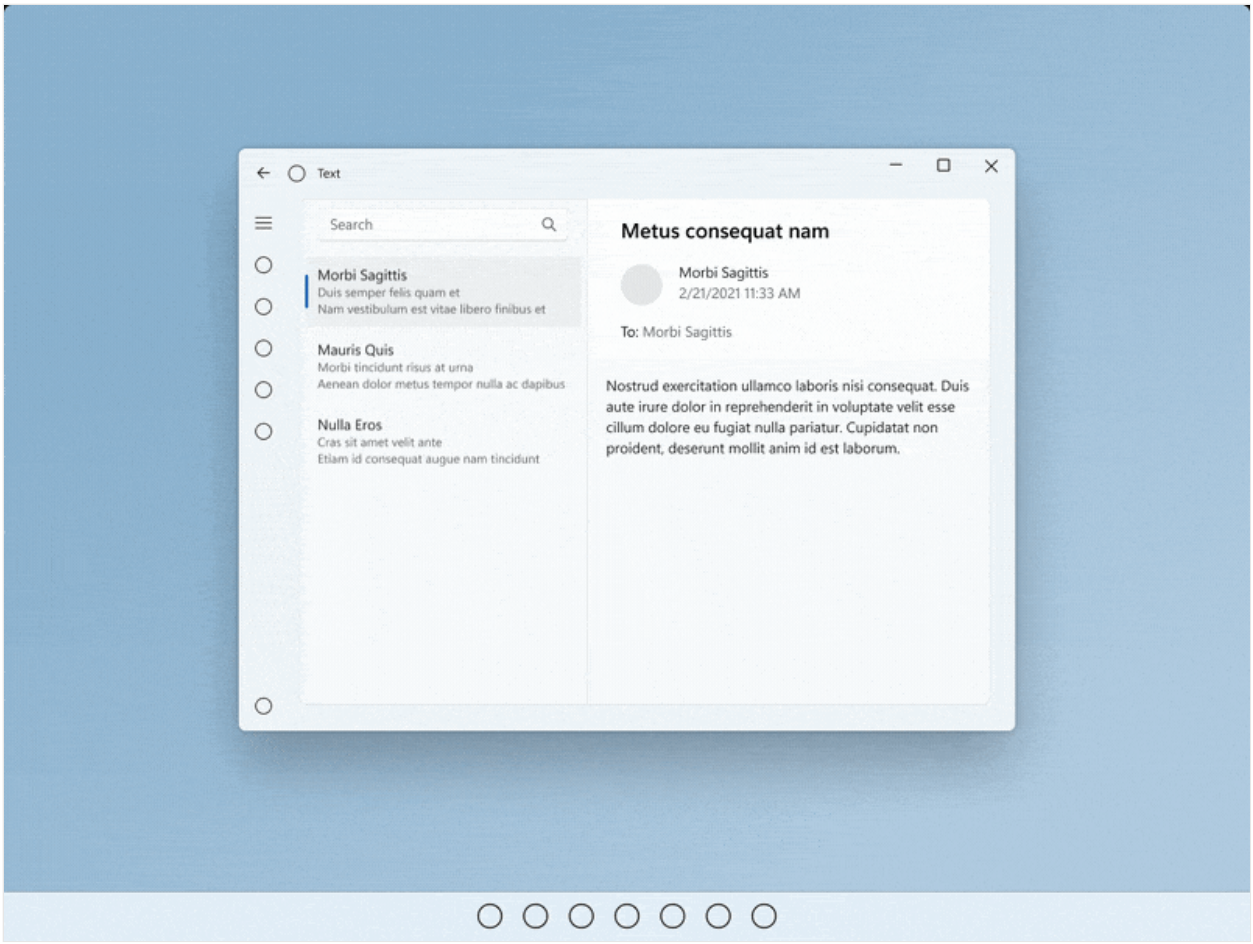
Gestures should also be actionable with flicks and swipes based on inertia and be within a comfortable range of motion.

- Drag or flick to go back and forth
- Drag to dismiss
- Pull to refresh

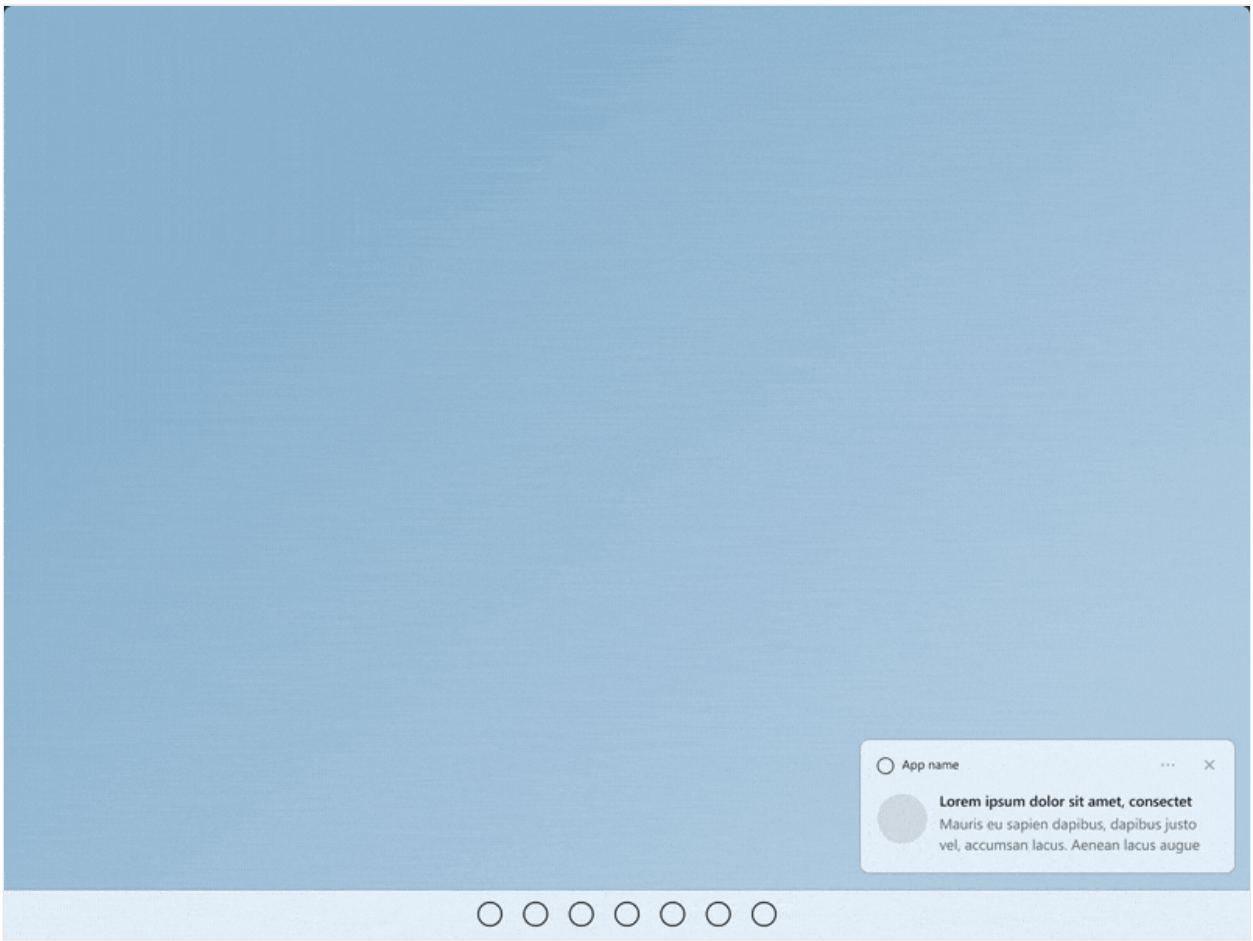
Gestures



Drag or flick to go back and forth



Pull to refresh



Drag to dismiss

For more info, see Page transitions and Pull to refresh.

Custom gestures

Use custom gestures to bring high frequency keyboard shortcut keys and trackpad gestures to a touch interaction. Aid discoverability and response through dedicated affordances with animations and visual states (for example, placing three fingers on screen causes windows to shrink for visual feedback).

- Do not override common gestures as this can cause confusion for users.
- Consider using multi-finger gestures for custom actions but be aware that the system has reserved some multi-finger gestures for rapid switching between apps and desktops.
- Be mindful of custom gestures originating near the edges of a screen as edge gestures are reserved for OS-level behaviors, which can be invoked accidentally.

Avoid accidental navigation

If you your app or game might involve frequent interactions near the edges of the screen, consider presenting your experience in a Fullscreen Exclusive (FSE) mode to avoid accidental activations of system flyouts (users will have to swipe directly on the temporary tab in order to pull in the associated system flyout).

> **Note**
>
> Avoid using this unless absolutely necessary as it will make it harder for users to navigate away from your app or use it in conjunction with others.

Touch keyboard experiences

The touch keyboard enables text entry for devices that support touch. Windows app text input controls invoke the touch keyboard by default when a user taps on an editable input field.

Invoke on text field tap

Touch keyboard should pop up when a user taps on a text input field – this will work automatically by using our system APIs to show and hide the keyboard. See Respond to the presence of the touch keyboard.

Use standard text input controls

Using common controls provides expected behavior and minimizes surprises for users.

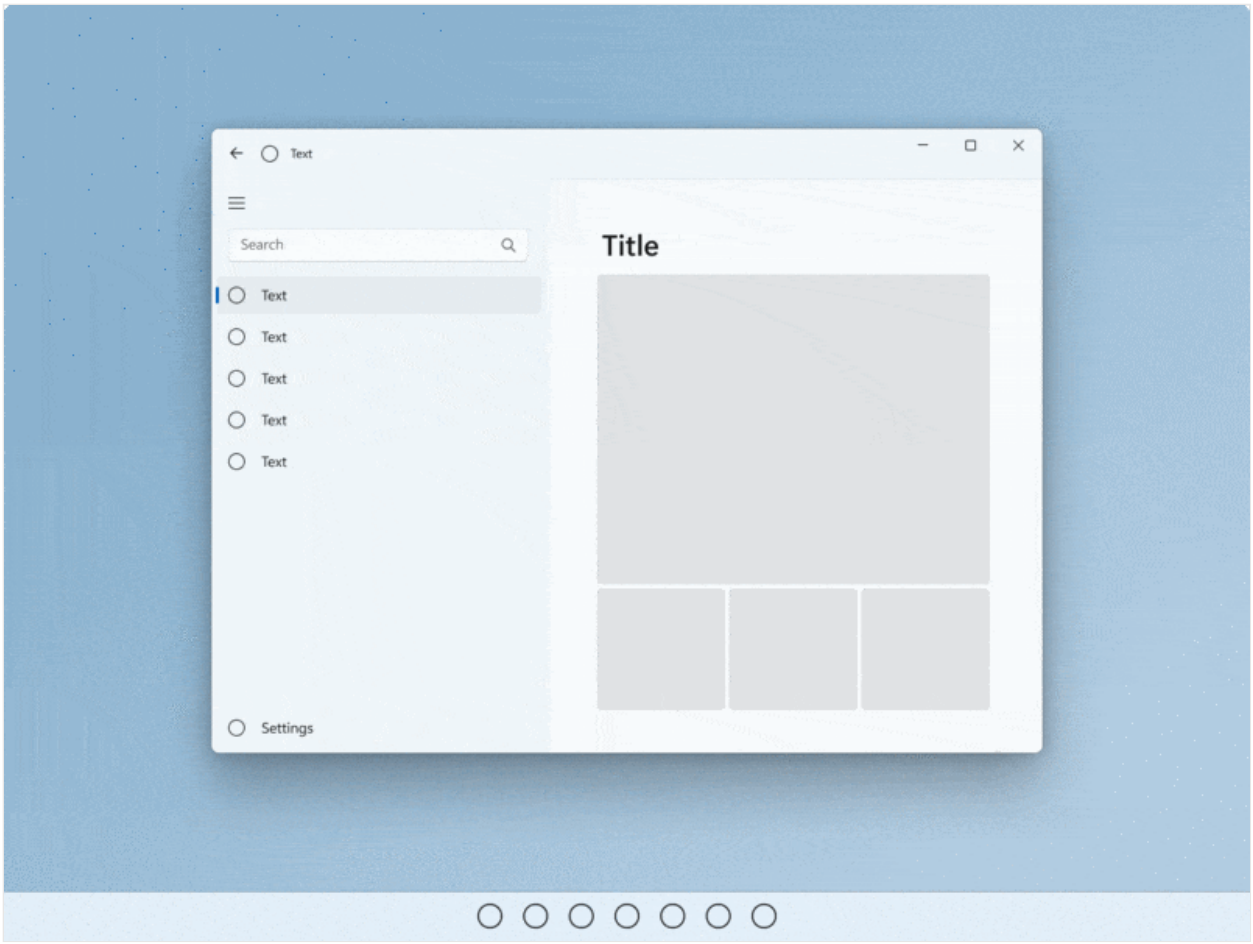
Text controls that support the Text Services Framework (TSF) provide shape-writing (swipe keyboard) capabilities.

Touch keyboard signals

Account for input, posture, hardware signals that make touch keyboard the main mode of input (hardware keyboard is detached, entrypoints are invoked with touch, clear user intent to type).

Reflow appropriately

- Be aware that the keyboard can take up 50% of the screen on smaller devices.
- Don't obscure the active text field with the touch keyboard.
- If the touch keyboard is obscuring the active text field, scroll the app content up (with animation) until the field is visible.
- If the touch keyboard is obscuring the active text field but the app content cannot scroll up, try to move the app container (with animation).



Hit Targets

Make sure hit targets are comfortable and inviting to touch. If hit targets are too small or crowded, users must be more precise, which is difficult with touch and can result in a poor experience.

Touchable

We define touchable as a minimum of 40 x 40 epx, even if the visual is smaller, or 32 epx tall if the width is at least 120 epx.

Our common controls conform to this standard (they are optimized for both mouse and touch users).

Touch-optimized

For a touch-optimized UI, consider increasing the target size to 44 x 44 epx with at least 4 epx of visible space between targets.

We recommend two default behaviors: Always touch optimized or transition based on device signals.

When an app can be optimized for touch without compromising mouse users, especially if the app is used primarily with touch, then always touch optimize.

If you transition the UI based on device signals for device posture, always provide consistent experiences across postures.

Match visuals to touch target

Consider updating visuals when touch target dimensions change. For example, if hit targets increase when users enter tablet posture, UI representing the hit targets should also update to help users understand the state change and updated affordance. For more info, see Content design basics for Windows apps, Guidelines for touch targets, Control size and density.

Portrait Optimization

Support responsive layouts that account for both tall and wide windows to ensure an app is optimized for both landscape and portrait orientations.

This will also ensure app windows display core UI visuals properly in multitasking scenarios (apps snapped side-by-side with portrait aspect ratios) regardless of orientation and screen sizes.

Touch interactions developer guide

Article • 01/19/2024

Design your app with the expectation that touch will be the primary input method of your users. If you use UWP controls, support for touchpad, mouse, and pen/stylus requires no additional programming, because UWP apps provide this for free.

However, keep in mind that a UI optimized for touch is not always superior to a traditional UI. Both provide advantages and disadvantages that are unique to a technology and application. In the move to a touch-first UI, it is important to understand the core differences between touch, touchpad, pen/stylus, mouse, and keyboard input.

> **Important APIs**: Windows.UI.Xaml.Input, Windows.UI.Core, Windows.Devices.Input

Many devices have multi-touch screens that support using one or more fingers (or touch contacts) as input. The touch contacts, and their movement, are interpreted as touch gestures and manipulations to support various user interactions.

The Windows app includes a number of different mechanisms for handling touch input, enabling you to create an immersive experience that your users can explore with confidence. Here, we cover the basics of using touch input in a Windows app.

Touch interactions require three things:

- A touch-sensitive display.
- The direct contact (or proximity to, if the display has proximity sensors and supports hover detection) of one or more fingers on that display.
- Movement of the touch contacts (or lack thereof, based on a time threshold).

The input data provided by the touch sensor can be:

- Interpreted as a physical gesture for direct manipulation of one or more UI elements, such as panning, rotating, resizing, or moving. (In contrast, interacting with an element through its properties window, dialog box, or other UI affordance is considered indirect manipulation.)
- Recognized as an alternative input method, such as mouse or pen.
- Used to complement or modify aspects of other input methods, such as smudging an ink stroke drawn with a pen.

Touch input typically involves the direct manipulation of an element on the screen. The element responds immediately to any touch contact within its hit test area, and reacts

appropriately to any subsequent movement of the touch contacts, including removal.

Custom touch gestures and interactions should be designed carefully. They should be intuitive, responsive, and discoverable, and they should let users explore your app with confidence.

Ensure that app functionality is exposed consistently across every supported input device type. If necessary, use some form of indirect input mode, such as text input for keyboard interactions, or UI affordances for mouse and pen.

Remember that traditional input devices (such as mouse and keyboard) are familiar and appealing to many users. They can offer speed, accuracy, and tactile feedback that touch cannot.

Providing unique and distinctive interaction experiences for all input devices will support the widest range of capabilities and preferences, appeal to the broadest possible audience, and attract more customers to your app.

Compare touch interaction requirements

The following table shows some of the differences between input devices that you should consider when you design touch-optimized Windows apps.

Expand table

Factor	Touch interactions	Mouse, keyboard, pen/stylus interactions	Touchpad
Precision	The contact area of a fingertip is greater than a single x-y coordinate, which increases the chances of unintended command activations.	The mouse and pen/stylus supply a precise x-y coordinate.	Same as mouse.
	The shape of the contact area changes throughout the movement.	Mouse movements and pen/stylus strokes supply precise x-y coordinates. Keyboard focus is explicit.	Same as mouse.
	There is no mouse cursor to assist with targeting.	The mouse cursor, pen/stylus cursor, and keyboard focus all assist with targeting.	Same as mouse.
Human anatomy	Fingertip movements are imprecise, because a straight-line motion with one or more fingers	It's easier to perform a straight-line motion with the mouse or pen/stylus because	Same as mouse.

	is difficult. This is due to the curvature of hand joints and the number of joints involved in the motion.	the hand that controls them travels a shorter physical distance than the cursor on the screen.	
	Some areas on the touch surface of a display device can be difficult to reach due to finger posture and the user's grip on the device.	The mouse and pen/stylus can reach any part of the screen while any control should be accessible by the keyboard through tab order.	Finger posture and grip can be an issue.
	Objects might be obscured by one or more fingertips or the user's hand. This is known as occlusion.	Indirect input devices do not cause occlusion.	Same as mouse.
Object state	Touch uses a two-state model: the touch surface of a display device is either touched (on) or not (off). There is no hover state that can trigger additional visual feedback.	A mouse, pen/stylus, and keyboard all expose a three-state model: up (off), down (on), and hover (focus). Hover lets users explore and learn through tooltips associated with UI elements. Hover and focus effects can relay which objects are interactive and also help with targeting.	Same as mouse.
Rich interaction	Supports multi-touch: multiple input points (fingertips) on a touch surface.	Supports a single input point.	Same as touch.
	Supports direct manipulation of objects through gestures such as tapping, dragging, sliding, pinching, and rotating.	No support for direct manipulation as mouse, pen/stylus, and keyboard are indirect input devices.	Same as mouse.

Note

Indirect input has had the benefit of more than 25 years of refinement. Features such as hover-triggered tooltips have been designed to solve UI exploration specifically for touchpad, mouse, pen/stylus, and keyboard input. UI features like this have been re-designed for the rich experience provided by touch input, without compromising the user experience for these other devices.

Use touch feedback

Appropriate visual feedback during interactions with your app helps users recognize, learn, and adapt to how their interactions are interpreted by both the app and the Windows platform. Visual feedback can indicate successful interactions, relay system status, improve the sense of control, reduce errors, help users understand the system and input device, and encourage interaction.

Visual feedback is critical when the user relies on touch input for activities that require accuracy and precision based on location. Display feedback whenever and wherever touch input is detected, to help the user understand any custom targeting rules that are defined by your app and its controls.

Targeting

Targeting is optimized through:

- Touch target sizes

  Clear size guidelines ensure that applications provide a comfortable UI that contains objects and controls that are easy and safe to target.

- Contact geometry

  The entire contact area of the finger determines the most likely target object.

- Scrubbing

  Items within a group are easily re-targeted by dragging the finger between them (for example, radio buttons). The current item is activated when the touch is released.

- Rocking

  Densely packed items (for example, hyperlinks) are easily re-targeted by pressing the finger down and, without sliding, rocking it back and forth over the items. Due to occlusion, the current item is identified through a tooltip or the status bar and is activated when the touch is released.

Accuracy

Design for sloppy interactions by using:

- Snap-points that can make it easier to stop at desired locations when users interact with content.
- Directional "rails" that can assist with vertical or horizontal panning, even when the hand moves in a slight arc. For more information, see Guidelines for panning.

Occlusion

Finger and hand occlusion is avoided through:

- Size and positioning of UI

  Make UI elements big enough so that they cannot be completely covered by a fingertip contact area.

  Position menus and pop-ups above the contact area whenever possible.

- Tooltips

  Show tooltips when a user maintains finger contact on an object. This is useful for describing object functionality. The user can drag the fingertip off the object to avoid invoking the tooltip.

  For small objects, offset tooltips so they are not covered by the fingertip contact area. This is helpful for targeting.

- Handles for precision

  Where precision is required (for example, text selection), provide selection handles that are offset to improve accuracy. For more information, see Guidelines for selecting text and images (Windows Runtime apps).

Timing

Avoid timed mode changes in favor of direct manipulation. Direct manipulation simulates the direct, real-time physical handling of an object. The object responds as the fingers are moved.

A timed interaction, on the other hand, occurs after a touch interaction. Timed interactions typically depend on invisible thresholds like time, distance, or speed to determine what command to perform. Timed interactions have no visual feedback until the system performs the action.

Direct manipulation provides a number of benefits over timed interactions:

- Instant visual feedback during interactions make users feel more engaged, confident, and in control.
- Direct manipulations make it safer to explore a system because they are reversible—users can easily step back through their actions in a logical and intuitive manner.
- Interactions that directly affect objects and mimic real world interactions are more intuitive, discoverable, and memorable. They don't rely on obscure or abstract interactions.
- Timed interactions can be difficult to perform, as users must reach arbitrary and invisible thresholds.

In addition, the following are strongly recommended:

- Manipulations should not be distinguished by the number of fingers used.
- Interactions should support compound manipulations. For example, pinch to zoom while dragging the fingers to pan.
- Interactions should not be distinguished by time. The same interaction should have the same outcome regardless of the time taken to perform it. Time-based activations introduce mandatory delays for users and detract from both the immersive nature of direct manipulation and the perception of system responsiveness.

  > **Note**
  >
  > An exception to this is where you use specific timed interactions to assist in learning and exploration (for example, press and hold).

- Appropriate descriptions and visual cues have a great effect on the use of advanced interactions.

App views

Tweak the user interaction experience through the pan/scroll and zoom settings of your app views. An app view dictates how a user accesses and manipulates your app and its content. Views also provide behaviors such as inertia, content boundary bounce, and snap points.

Pan and scroll settings of the ScrollViewer control dictate how users navigate within a single view, when the content of the view doesn't fit within the viewport. A single view, for example, can be a page of a magazine or book, the folder structure of a computer, a library of documents, or a photo album.

Zoom settings apply to both optical zoom (supported by the **ScrollViewer** control) and the **Semantic Zoom** control. Semantic Zoom is a touch-optimized technique for presenting and navigating large sets of related data or content within a single view. It works by using two distinct modes of classification, or zoom levels. This is analogous to panning and scrolling within a single view. Panning and scrolling can be used in conjunction with Semantic Zoom.

Use app views and events to modify the pan/scroll and zoom behaviors. This can provide a smoother interaction experience than is possible through the handling of pointer and gesture events.

For more info about app views, see Controls, layouts, and text.

Custom touch interactions

If you implement your own interaction support, keep in mind that users expect an intuitive experience involving direct interaction with the UI elements in your app. We recommend that you model your custom interactions on the platform control libraries to keep things consistent and discoverable. The controls in these libraries provide the full user interaction experience, including standard interactions, animated physics effects, visual feedback, and accessibility. Create custom interactions only if there is a clear, well-defined requirement and basic interactions don't support your scenario.

> ⓘ **Important**
>
> **Windows 11 and newer**
>
> *Some three- and four-finger touch interactions will no longer work in Windows apps by default.*
>
> By default, three- and four-finger touch interactions are now consumed by the system for operations such as switching or minimizing windows and changing virtual desktops. As these interactions are now handled at the system level, your app's functionality could be affected by this change.
>
> To support three- or four-finger interactions within an application, a new user setting has been introduced that specifies whether or not the system handles these interactions:
>
> **Bluetooth & devices > Touch > "Three- and four-finger touch gestures"**
>
> When set to "On" (default), the system will handle all three- and four-finger interactions (apps will not be able to support them).

When set to "Off", three- and four-finger interactions can be supported by apps (they will not be handled by the system).

If your application must support these interactions, we recommend that you inform users of this setting and provide a link that launches the Settings app to the relevant page (ms-settings:devices-touch). For more details, see **Launch the Windows Settings app**.

To provide customized touch support, you can handle various **UIElement** events. These events are grouped into three levels of abstraction.

- Static gesture events are triggered after an interaction is complete. Gesture events include **Tapped**, **DoubleTapped**, **RightTapped**, and **Holding**.

  You can disable gesture events on specific elements by setting **IsTapEnabled**, **IsDoubleTapEnabled**, **IsRightTapEnabled**, and **IsHoldingEnabled** to **false**.

- Pointer events such as **PointerPressed** and **PointerMoved** provide low-level details for each touch contact, including pointer motion and the ability to distinguish press and release events.

  A pointer is a generic input type with a unified event mechanism. It exposes basic info, such as screen position, on the active input source, which can be touch, touchpad, mouse, or pen.

- Manipulation gesture events, such as **ManipulationStarted**, indicate an ongoing interaction. They start firing when the user touches an element and continue until the user lifts their finger(s), or the manipulation is canceled.

  Manipulation events include multi-touch interactions such as zooming, panning, or rotating, and interactions that use inertia and velocity data such as dragging. The information provided by the manipulation events doesn't identify the form of the interaction that was performed, but rather includes data such as position, translation delta, and velocity. You can use this touch data to determine the type of interaction that should be performed.

Here is the basic set of touch gestures supported by UWP.

Expand table

Name	Type	Description
Tap	Static gesture	One finger touches the screen and lifts up.

Name	Type	Description
Press and hold	Static gesture	One finger touches the screen and stays in place.
Slide	Manipulation gesture	One or more fingers touch the screen and move in the same direction.
Swipe	Manipulation gesture	One or more fingers touch the screen and move a short distance in the same direction.
Turn	Manipulation gesture	Two or more fingers touch the screen and move in a clockwise or counter-clockwise arc.
Pinch	Manipulation gesture	Two or more fingers touch the screen and move closer together.
Stretch	Manipulation gesture	Two or more fingers touch the screen and move farther apart.

Gesture events

For details about individual controls, see Controls list.

Pointer events

Pointer events are raised by a variety of active input sources, including touch, touchpad, pen, and mouse (they replace traditional mouse events.)

Pointer events are based on a single input point (finger, pen tip, mouse cursor) and do not support velocity-based interactions.

Here is a list of pointer events and their related event argument.

Expand table

Event or class	Description
PointerPressed	Occurs when a single finger touches the screen.
PointerReleased	Occurs when that same touch contact is lifted.
PointerMoved	Occurs when the pointer is dragged across the screen.
PointerEntered	Occurs when a pointer enters the hit test area of an element.
PointerExited	Occurs when a pointer exits the hit test area of an element.

Event or class	Description
PointerCanceled	Occurs when a touch contact is abnormally lost.
PointerCaptureLost	Occurs when a pointer capture is taken by another element.
PointerWheelChanged	Occurs when the delta value of a mouse wheel changes and when the touchpad is pinched.
PointerRoutedEventArgs	Provides data for all pointer events.

The following example shows how to use the PointerPressed, PointerReleased, and PointerExited events to handle a tap interaction on a Rectangle object.

First, a Rectangle named `touchRectangle` is created in Extensible Application Markup Language (XAML).

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Rectangle Name="touchRectangle"
           Height="100" Width="200" Fill="Blue" />
</Grid>
```

Next, listeners for the PointerPressed, PointerReleased, and PointerExited events are specified.

C++

```
MainPage::MainPage()
{
    InitializeComponent();

    // Pointer event listeners.
    touchRectangle->PointerPressed += ref new PointerEventHandler(this,
&MainPage::touchRectangle_PointerPressed);
    touchRectangle->PointerReleased += ref new PointerEventHandler(this,
&MainPage::touchRectangle_PointerReleased);
    touchRectangle->PointerExited += ref new PointerEventHandler(this,
&MainPage::touchRectangle_PointerExited);
}
```

cs

```
public MainPage()
{
    this.InitializeComponent();

    // Pointer event listeners.
```

```
    touchRectangle.PointerPressed += touchRectangle_PointerPressed;
    touchRectangle.PointerReleased += touchRectangle_PointerReleased;
    touchRectangle.PointerExited += touchRectangle_PointerExited;
}
```

VB

```
Public Sub New()

    ' This call is required by the designer.
    InitializeComponent()

    ' Pointer event listeners.
    AddHandler touchRectangle.PointerPressed, AddressOf
touchRectangle_PointerPressed
    AddHandler touchRectangle.PointerReleased, AddressOf
Me.touchRectangle_PointerReleased
    AddHandler touchRectangle.PointerExited, AddressOf
touchRectangle_PointerExited

End Sub
```

Finally, the **PointerPressed** event handler increases the **Height** and **Width** of the **Rectangle**, while the **PointerReleased** and **PointerExited** event handlers set the **Height** and **Width** back to their starting values.

C++

```
// Handler for pointer exited event.
void MainPage::touchRectangle_PointerExited(Object^ sender,
PointerRoutedEventArgs^ e)
{
    Rectangle^ rect = (Rectangle^)sender;

    // Pointer moved outside Rectangle hit test area.
    // Reset the dimensions of the Rectangle.
    if (nullptr != rect)
    {
        rect->Width = 200;
        rect->Height = 100;
    }
}

// Handler for pointer released event.
void MainPage::touchRectangle_PointerReleased(Object^ sender,
PointerRoutedEventArgs^ e)
{
    Rectangle^ rect = (Rectangle^)sender;

    // Reset the dimensions of the Rectangle.
    if (nullptr != rect)
```

```
    {
        rect->Width = 200;
        rect->Height = 100;
    }
}

// Handler for pointer pressed event.
void MainPage::touchRectangle_PointerPressed(Object^ sender,
PointerRoutedEventArgs^ e)
{
    Rectangle^ rect = (Rectangle^)sender;

    // Change the dimensions of the Rectangle.
    if (nullptr != rect)
    {
        rect->Width = 250;
        rect->Height = 150;
    }
}
```

cs

```
// Handler for pointer exited event.
private void touchRectangle_PointerExited(object sender,
PointerRoutedEventArgs e)
{
    Rectangle rect = sender as Rectangle;

    // Pointer moved outside Rectangle hit test area.
    // Reset the dimensions of the Rectangle.
    if (null != rect)
    {
        rect.Width = 200;
        rect.Height = 100;
    }
}
// Handler for pointer released event.
private void touchRectangle_PointerReleased(object sender,
PointerRoutedEventArgs e)
{
    Rectangle rect = sender as Rectangle;

    // Reset the dimensions of the Rectangle.
    if (null != rect)
    {
        rect.Width = 200;
        rect.Height = 100;
    }
}

// Handler for pointer pressed event.
private void touchRectangle_PointerPressed(object sender,
PointerRoutedEventArgs e)
```

```
{
    Rectangle rect = sender as Rectangle;

    // Change the dimensions of the Rectangle.
    if (null != rect)
    {
        rect.Width = 250;
        rect.Height = 150;
    }
}
```

VB

```
' Handler for pointer exited event.
Private Sub touchRectangle_PointerExited(sender As Object, e As
PointerRoutedEventArgs)
    Dim rect As Rectangle = CType(sender, Rectangle)

    ' Pointer moved outside Rectangle hit test area.
    ' Reset the dimensions of the Rectangle.
    If (rect IsNot Nothing) Then
        rect.Width = 200
        rect.Height = 100
    End If
End Sub

' Handler for pointer released event.
Private Sub touchRectangle_PointerReleased(sender As Object, e As
PointerRoutedEventArgs)
    Dim rect As Rectangle = CType(sender, Rectangle)

    ' Reset the dimensions of the Rectangle.
    If (rect IsNot Nothing) Then
        rect.Width = 200
        rect.Height = 100
    End If
End Sub

' Handler for pointer pressed event.
Private Sub touchRectangle_PointerPressed(sender As Object, e As
PointerRoutedEventArgs)
    Dim rect As Rectangle = CType(sender, Rectangle)

    ' Change the dimensions of the Rectangle.
    If (rect IsNot Nothing) Then
        rect.Width = 250
        rect.Height = 150
    End If
End Sub
```

Manipulation events

Use manipulation events in your app if you need to support multiple finger interactions or interactions that require velocity data.

You can use manipulation events to detect interactions such as drag, zoom, and hold.

> **Note**
>
> The touchpad does not raise Manipulation events. Instead, pointer events will be raised for touchpad input.

Here is a list of manipulation events and related event arguments.

Expand table

Event or class	Description
ManipulationStarting event	Occurs when the manipulation processor is first created.
ManipulationStarted event	Occurs when an input device begins a manipulation on the UIElement.
ManipulationDelta event	Occurs when the input device changes position during a manipulation.
ManipulationInertiaStarting event	Occurs when the input device loses contact with the UIElement object during a manipulation and inertia begins.
ManipulationCompleted event	Occurs when a manipulation and inertia on the UIElement are complete.
ManipulationStartingRoutedEventArgs	Provides data for the ManipulationStarting event.
ManipulationStartedRoutedEventArgs	Provides data for the ManipulationStarted event.
ManipulationDeltaRoutedEventArgs	Provides data for the ManipulationDelta event.
ManipulationInertiaStartingRoutedEventArgs	Provides data for the ManipulationInertiaStarting event.
ManipulationVelocities	Describes the speed at which manipulations occur.
ManipulationCompletedRoutedEventArgs	Provides data for the ManipulationCompleted event.

A gesture consists of a series of manipulation events. Each gesture starts with a ManipulationStarted event, such as when a user touches the screen.

Next, one or more ManipulationDelta events are fired. For example, if you touch the screen and then drag your finger across the screen. Finally, a ManipulationCompleted event is raised when the interaction finishes.

> **Note**
>
> If you don't have a touch-screen monitor, you can test your manipulation event code in the simulator using a mouse and mouse wheel interface.

The following example shows how to use the ManipulationDelta events to handle a slide interaction on a Rectangle and move it across the screen.

First, a Rectangle named `touchRectangle` is created in XAML with a Height and Width of 200.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Rectangle Name="touchRectangle"
               Width="200" Height="200" Fill="Blue"
               ManipulationMode="All"/>
</Grid>
```

Next, a global TranslateTransform named `dragTranslation` is created for translating the Rectangle. A ManipulationDelta event listener is specified on the **Rectangle**, and `dragTranslation` is added to the RenderTransform of the **Rectangle**.

C++

```
// Global translation transform used for changing the position of
// the Rectangle based on input data from the touch contact.
Windows::UI::Xaml::Media::TranslateTransform^ dragTranslation;
```

cs

```
// Global translation transform used for changing the position of
// the Rectangle based on input data from the touch contact.
private TranslateTransform dragTranslation;
```

VB

```
' Global translation transform used for changing the position of
' the Rectangle based on input data from the touch contact.
Private dragTranslation As TranslateTransform
```

C++

```
MainPage::MainPage()
{
    InitializeComponent();

    // Listener for the ManipulationDelta event.
    touchRectangle->ManipulationDelta +=
        ref new ManipulationDeltaEventHandler(
            this,
            &MainPage::touchRectangle_ManipulationDelta);
    // New translation transform populated in
    // the ManipulationDelta handler.
    dragTranslation = ref new TranslateTransform();
    // Apply the translation to the Rectangle.
    touchRectangle->RenderTransform = dragTranslation;
}
```

cs

```
public MainPage()
{
    this.InitializeComponent();

    // Listener for the ManipulationDelta event.
    touchRectangle.ManipulationDelta += touchRectangle_ManipulationDelta;
    // New translation transform populated in
    // the ManipulationDelta handler.
    dragTranslation = new TranslateTransform();
    // Apply the translation to the Rectangle.
    touchRectangle.RenderTransform = this.dragTranslation;
}
```

VB

```
Public Sub New()

    ' This call is required by the designer.
    InitializeComponent()

    ' Listener for the ManipulationDelta event.
    AddHandler touchRectangle.ManipulationDelta,
        AddressOf testRectangle_ManipulationDelta
    ' New translation transform populated in
    ' the ManipulationDelta handler.
    dragTranslation = New TranslateTransform()
```

```
    ' Apply the translation to the Rectangle.
    touchRectangle.RenderTransform = dragTranslation

End Sub
```

Finally, in the **ManipulationDelta** event handler, the position of the **Rectangle** is updated by using the **TranslateTransform** on the **Delta** property.

C++

```
// Handler for the ManipulationDelta event.
// ManipulationDelta data is loaded into the
// translation transform and applied to the Rectangle.
void MainPage::touchRectangle_ManipulationDelta(Object^ sender,
    ManipulationDeltaRoutedEventArgs^ e)
{
    // Move the rectangle.
    dragTranslation->X += e->Delta.Translation.X;
    dragTranslation->Y += e->Delta.Translation.Y;

}
```

cs

```
// Handler for the ManipulationDelta event.
// ManipulationDelta data is loaded into the
// translation transform and applied to the Rectangle.
void touchRectangle_ManipulationDelta(object sender,
    ManipulationDeltaRoutedEventArgs e)
{
    // Move the rectangle.
    dragTranslation.X += e.Delta.Translation.X;
    dragTranslation.Y += e.Delta.Translation.Y;
}
```

VB

```
' Handler for the ManipulationDelta event.
' ManipulationDelta data Is loaded into the
' translation transform And applied to the Rectangle.
Private Sub testRectangle_ManipulationDelta(
    sender As Object,
    e As ManipulationDeltaRoutedEventArgs)

    ' Move the rectangle.
    dragTranslation.X = (dragTranslation.X + e.Delta.Translation.X)
    dragTranslation.Y = (dragTranslation.Y + e.Delta.Translation.Y)

End Sub
```

Routed events

All of the pointer events, gesture events and manipulation events mentioned here are implemented as *routed events*. This means that the event can potentially be handled by objects other than the one that originally raised the event. Successive parents in an object tree, such as the parent containers of a **UIElement** or the root **Page** of your app, can choose to handle these events even if the original element does not. Conversely, any object that does handle the event can mark the event handled so that it no longer reaches any parent element. For more info about the routed event concept and how it affects how you write handlers for routed events, see Events and routed events overview.

> **ⓘ Important**
>
> If you need to handle pointer events for a **UIElement** in a scrollable view (such as a ScrollViewer or ListView), you must explicitly disable support for manipulation events on the element in the view by calling **UIElement.CancelDirectmanipulation()**. To re-enable manipulation events in the view, call **UIElement.TryStartDirectManipulation()**.

Dos and don'ts

- Design applications with touch interaction as the primary expected input method.
- Provide visual feedback for interactions of all types (touch, pen, stylus, mouse, etc.)
- Optimize targeting by adjusting touch target size, contact geometry, scrubbing and rocking.
- Optimize accuracy through the use of snap points and directional "rails".
- Provide tooltips and handles to help improve touch accuracy for tightly packed UI items.
- Don't use timed interactions whenever possible (example of appropriate use: touch and hold).
- Don't use the number of fingers used to distinguish the manipulation whenever possible.

Mouse interactions

Article • 06/24/2021

Optimize your Windows app design for touch input and get basic mouse support by default.

Mouse input is best suited for user interactions that require precision when pointing and clicking. This inherent precision is naturally supported by the UI of Windows, which is optimized for the imprecise nature of touch.

Where mouse and touch input diverge is the ability for touch to more closely emulate the direct manipulation of UI elements through physical gestures performed directly on those objects (such as swiping, sliding, dragging, rotating, and so on). Manipulations with a mouse typically require some other UI affordance, such as the use of handles to resize or rotate an object.

This topic describes design considerations for mouse interactions.

The UWP app mouse language

A concise set of mouse interactions are used consistently throughout the system.

Term	Description
Hover to learn	Hover over an element to display more detailed info or teaching visuals (such as a tooltip) without a commitment to an action.
Left-click for primary action	Left-click an element to invoke its primary action (such as launching an app or executing a command).

Term	Description
Scroll to change view	Display scroll bars to move up, down, left, and right within a content area. Users can scroll by clicking scroll bars or rotating the mouse wheel. Scroll bars can indicate the location of the current view within the content area (panning with touch displays a similar UI).
Right-click to select and command	Right-click to display the navigation bar (if available) and the app bar with global commands. Right-click an element to select it and display the app bar with contextual commands for the selected element. **Note** Right-click to display a context menu if selection or app bar commands are not appropriate UI behaviors. But we strongly recommend that you use the app bar for all command behaviors.
UI commands to zoom	Display UI commands in the app bar (such as + and -), or press Ctrl and rotate mouse wheel, to emulate pinch and stretch gestures for zooming.
UI commands to rotate	Display UI commands in the app bar, or press Ctrl+Shift and rotate mouse wheel, to emulate the turn gesture for rotating. Rotate the device itself to rotate the entire screen.
Left-click and drag to rearrange	Left-click and drag an element to move it.
Left-click and drag to select text	Left-click within selectable text and drag to select it. Double-click to select a word.

Mouse input events

Most mouse input can be handled through the common routed input events supported by all **UIElement** objects. These include:

- **BringIntoViewRequested**
- **CharacterReceived**
- **ContextCanceled**

- ContextRequested
- DoubleTapped
- DragEnter
- DragLeave
- DragOver
- DragStarting
- Drop
- DropCompleted
- GettingFocus
- GotFocus
- Holding
- KeyDown
- KeyUp
- LosingFocus
- LostFocus
- ManipulationCompleted
- ManipulationDelta
- ManipulationInertiaStarting
- ManipulationStarted
- ManipulationStarting
- NoFocusCandidateFound
- PointerCanceled
- PointerCaptureLost
- PointerEntered
- PointerExited
- PointerMoved
- PointerPressed
- PointerReleased
- PointerWheelChanged
- PreviewKeyDown
- PreviewKeyUp
- RightTapped
- Tapped

However, you can take advantage of the specific capabilities of each device (such as mouse wheel events) using the pointer, gesture, and manipulation events in Windows.UI.Input.

Samples: See our BasicInput sample, for .

Guidelines for visual feedback

- When a mouse is detected (through move or hover events), show mouse-specific UI to indicate functionality exposed by the element. If the mouse doesn't move for a certain amount of time, or if the user initiates a touch interaction, make the mouse UI gradually fade away. This keeps the UI clean and uncluttered.
- Don't use the cursor for hover feedback, the feedback provided by the element is sufficient (see Cursors below).
- Don't display visual feedback if an element doesn't support interaction (such as static text).
- Don't use focus rectangles with mouse interactions. Reserve these for keyboard interactions.
- Display visual feedback concurrently for all elements that represent the same input target.
- Provide buttons (such as + and -) for emulating touch-based manipulations such as panning, rotating, zooming, and so on.

For more general guidance on visual feedback, see Guidelines for visual feedback.

Cursors

A set of standard cursors is available for a mouse pointer. These are used to indicate the primary action of an element.

Each standard cursor has a corresponding default image associated with it. The user or an app can replace the default image associated with any standard cursor at any time. Specify a cursor image through the **PointerCursor** function.

If you need to customize the mouse cursor:

- Always use the arrow cursor ( ) for clickable elements. don't use the pointing hand cursor ( ) for links or other interactive elements. Instead, use hover effects (described earlier).
- Use the text cursor ( ) for selectable text.
- Use the move cursor ( ) when moving is the primary action (such as dragging or cropping). Don't use the move cursor for elements where the primary action is navigation (such as Start tiles).
- Use the horizontal, vertical and diagonal resize cursors ( ), when an object is resizable.
- Use the grasping hand cursors ( ) when panning content within a fixed canvas (such as a map).

Keyboard interactions

Article • 06/11/2024

Learn how to design and optimize your Windows apps so they provide the best experiences for both keyboard power users and those with disabilities and other accessibility requirements.

Across devices, keyboard input is an important part of the overall Windows app interaction experience. A well-designed keyboard experience lets users efficiently navigate the UI of your app and access its full functionality without ever lifting their hands from the keyboard.

Common interaction patterns are shared between keyboard and gamepad

In this topic, we focus specifically on Windows app design for keyboard input on PCs. However, a well-designed keyboard experience is important for supporting accessibility tools such as Windows Narrator, using software keyboards such as the touch keyboard and the On-Screen Keyboard (OSK), and for handling other input device types, such as a game pad or remote control.

Many of the guidelines and recommendations discussed here, including focus visuals, access keys, and UI navigation, are also applicable to these other scenarios.

NOTE While both hardware and software keyboards are used for text input, the focus of this topic is navigation and interaction.

Built-in support

Along with the mouse, the keyboard is the most widely used peripheral on PCs and, as such, is a fundamental part of the PC experience. PC users expect a comprehensive and consistent experience from both the system and individual apps in response to keyboard input.

All UWP controls include built-in support for rich keyboard experiences and user interactions, while the platform itself provides an extensive foundation for creating keyboard experiences that you feel are best suited to both your custom controls and apps.

UWP supports keyboard with any device

Basic experiences

As mentioned previously, input devices such as a game pad and remote control, and accessibility tools such as Narrator, share much of the keyboard input experience for navigation and commanding. This common experience across input types and tools minimizes additional work from you and contributes to the "build once, run anywhere" goal of the Universal Windows Platform.

Where necessary, we'll identify key differences you should be aware of and describe any mitigations you should consider.

Here are the devices and tools discussed in this topic:

Expand table

Device/tool	Description
Keyboard (hardware and software)	In addition to the standard hardware keyboard, Windows applications support two software keyboards: the touch (or software) keyboard and the On-Screen Keyboard.
Game pad and remote control	A game pad and remote control are fundamental input devices in the 10-foot experience. For specific details on Windows support for game pad and remote control, see Game pad and remote control interactions.
Screen readers (Narrator)	Narrator is a built-in screen reader for Windows that provides unique interaction experiences and functionality, but still relies on basic keyboard navigation and input. For Narrator details, see Getting started with Narrator.

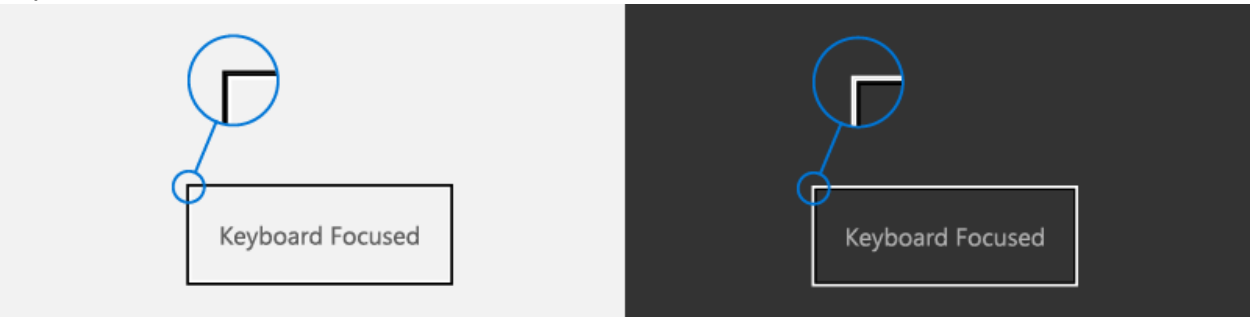
Custom experiences and efficient keyboarding

As mentioned, keyboard support is integral to ensuring your applications work great for users with different skills, abilities, and expectations. We recommend that you prioritize the following.

- Support keyboard navigation and interaction
  - Ensure actionable items are identified as tab stops (and non-actionable items are not), and navigation order is logical and predictable (see Tab stops)
  - Set initial focus on the most logical element (see Initial focus)
  - Provide arrow key navigation for "inner navigations" (see Navigation)
- Support keyboard shortcuts
  - Provide accelerator keys for quick actions (see Accelerators)
  - Provide access keys to navigate your application's UI (see Access keys)

Focus visuals

The UWP supports a single focus visual design that works well for all input types and experiences.



A focus visual:

- Is shown when a UI element receives focus from a keyboard and/or gamepad/remote control
- Is rendered as a highlighted border around the UI element to indicate an action can be taken
- Helps a user navigate an app UI without getting lost
- Can be customized for your app (See High visibility focus visuals)

NOTE The UWP focus visual is not the same as the Narrator focus rectangle.

Tab stops

To use a control (including navigation elements) with the keyboard, the control must have focus. One way for a control to receive keyboard focus is to make it accessible through tab navigation by identifying it as a tab stop in your application's tab order.

For a control to be included in the tab order, the IsEnabled property must be set to **true** and the IsTabStop property must be set to **true**.

To specifically exclude a control from the tab order, set the IsTabStop property to **false**.

By default, tab order reflects the order in which UI elements are created. For example, if a `StackPanel` contains a `Button`, a `Checkbox`, and a `TextBox`, tab order is `Button`, `Checkbox`, and `TextBox`.

You can override the default tab order by setting the TabIndex property.

Tab order should be logical and predictable

A well-designed keyboard navigation model, using a logical and predictable tab order, makes your app more intuitive and helps users explore, discover, and access functionality more efficiently and effectively.

All interactive controls should have tab stops (unless they are in a group), while non-interactive controls, such as labels, should not.

Avoid a custom tab order that makes the focus jump around in your application. For example, a list of controls in a form should have a tab order that flows from top to bottom and left to right (depending on locale).

See Keyboard accessibility for more details about customizing tab stops.

Try to coordinate tab order and visual order

Coordinating tab order and visual order (also referred to as reading order or display order) helps reduce confusion for users as they navigate through your application's UI.

Try to rank and present the most important commands, controls, and content first in both the tab order and the visual order. However, the actual display position can depend on the parent layout container and certain properties of the child elements that influence the layout. Specifically, layouts that use a grid metaphor or a table metaphor can have a visual order quite different from the tab order.

NOTE Visual order is also dependent on locale and language.

Initial focus

Initial focus specifies the UI element that receives focus when an application or a page is first launched or activated. When using a keyboard, it is from this element that a user starts interacting with your application's UI.

For UWP apps, initial focus is set to the element with the highest TabIndex that can receive focus. Child elements of container controls are ignored. In a tie, the first element in the visual tree receives focus.

Set initial focus on the most logical element

Set initial focus on the UI element for the first, or primary, action that users are most likely to take when launching your app or navigating to a page. Some examples include:

- A photo app where focus is set to the first item in a gallery
- A music app where focus is set to the play button

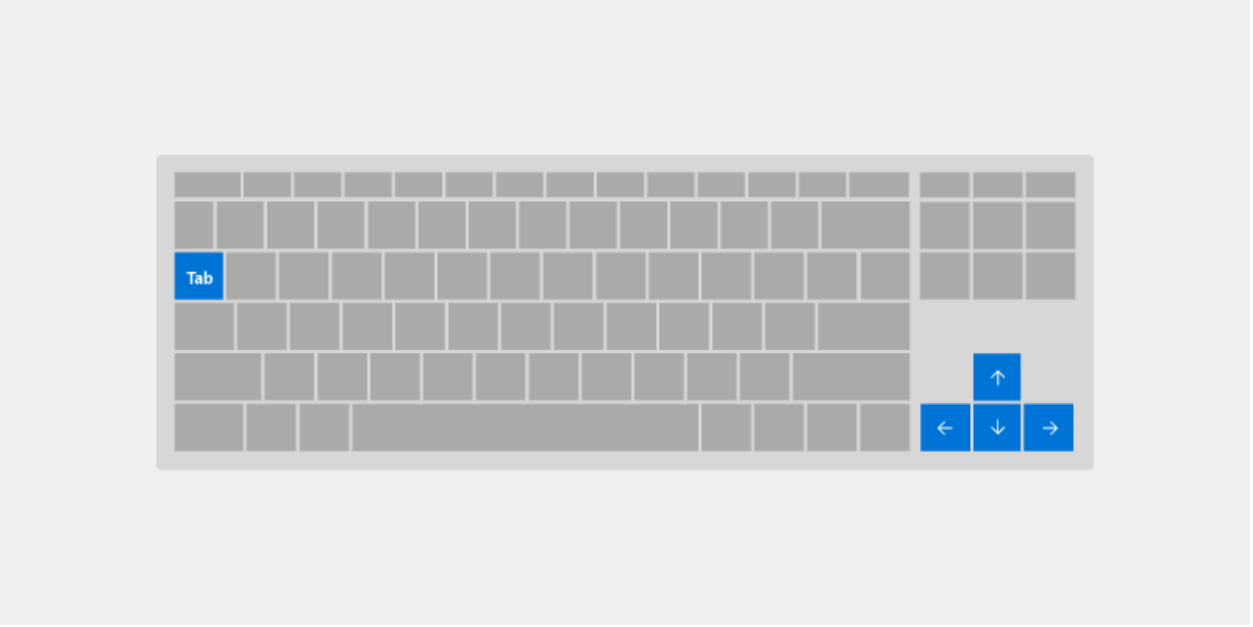
Don't set initial focus on an element that exposes a potentially negative, or even disastrous, outcome

This level of functionality should be a user's choice. Setting initial focus to an element with a significant outcome might result in unintended data loss or system access. For example, don't set focus to the delete button when navigating to an e-mail.

See Focus navigation for more details about overriding tab order.

Navigation

Keyboard navigation is typically supported through the Tab keys and the Arrow keys.



By default, UWP controls follow these basic keyboard behaviors:

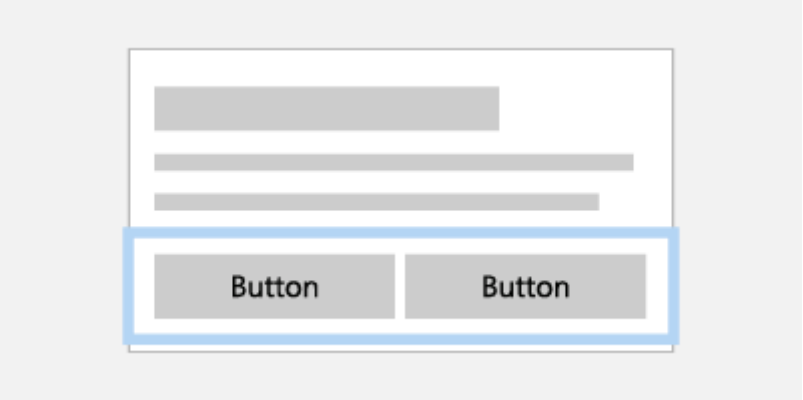
- **Tab keys** navigate between actionable/active controls in tab order.
- **Shift + Tab** navigate controls in reverse tab order. If user has navigated inside the control using arrow key, focus is set to the last known value inside the control.
- **Arrow keys** expose control-specific "inner navigation" When user enters "inner navigation,"" arrow keys do not navigate out of a control. Some examples include:
  - Up/Down arrow key moves focus inside `ListView` and `MenuFlyout`
  - Modify currently selected values for `Slider` and `RatingsControl`
  - Move caret inside `TextBox`
  - Expand/collapse items inside `TreeView`

Use these default behaviors to optimize your application's keyboard navigation.

Use "inner navigation" with sets of related controls

Providing arrow key navigation into a set of related controls reinforces their relationship within the overall organization of your application's UI.

For example, the `ContentDialog` control shown here provides inner navigation by default for a horizontal row of buttons (for custom controls, see the Control Group section).



Interaction with a collection of related buttons is made easier with arrow key navigation

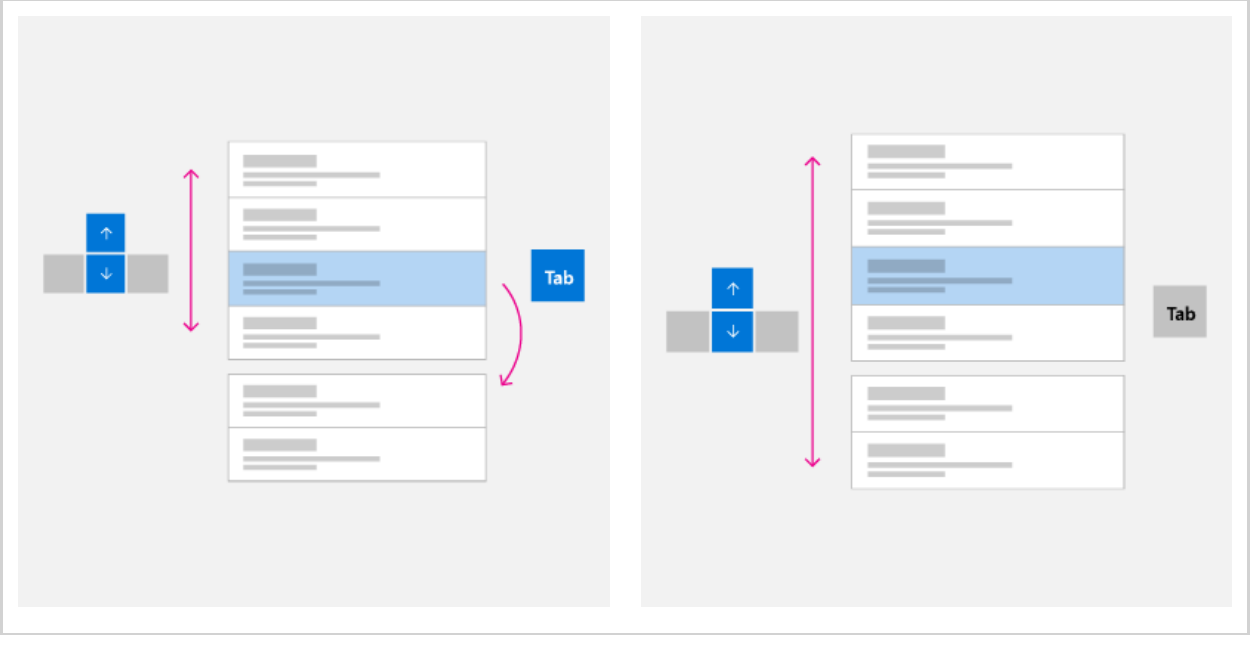
If items are displayed in a single column, Up/Down arrow key navigates items. If items are displayed in a single row, Right/Left arrow key navigates items. If items are multiple columns, all 4 arrow keys navigate.

Define a single tab stop for a collection of related controls

By defining a single tab stop for a collection of related, or complementary, controls, you can minimize the number of overall tab stops in your app.

For example, the following images show two stacked `ListView` controls. The image on the left shows arrow key navigation used with a tab stop to navigate between `ListView` controls, while the image on the right shows how navigation between child elements could be made easier and more efficient by eliminating the need for to traverse parent controls with a tab key.

Expand table



Interaction with two stacked ListView controls can be made easier and more efficient by eliminating the tab stop and navigating with just arrow keys.

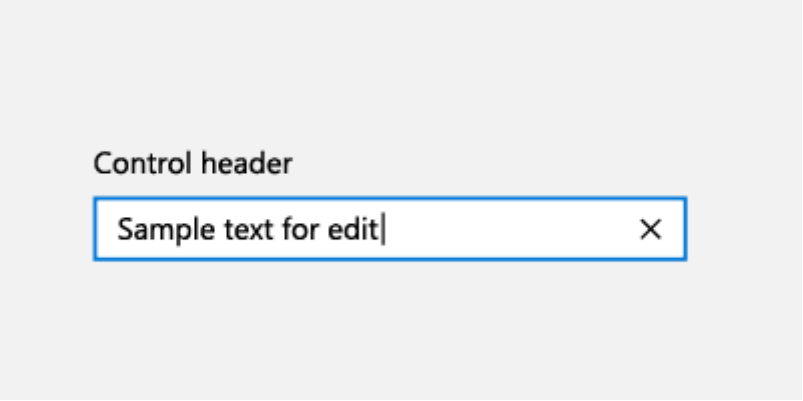
Visit Control Group section to learn how to apply the optimization examples to your application UI.

Interaction and commanding

Once a control has focus, a user can interact with it and invoke any associated functionality using specific keyboard input.

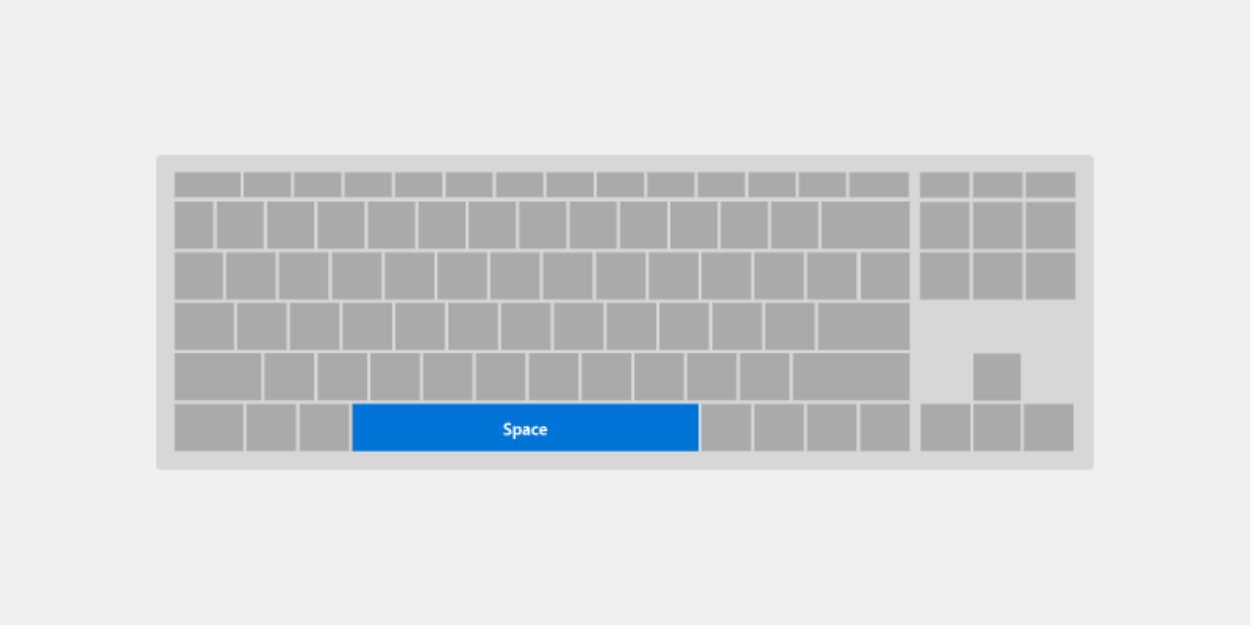
Text entry

For those controls specifically designed for text input such as `TextBox` and `RichEditBox`, all keyboard input is used for entering or navigating text, which takes priority over other keyboard commands. For example, the drop down menu for an `AutoSuggestBox` control does not recognize the **Space** key as a selection command.



Space key

When not in text entry mode, the **Space** key invokes the action or command associated with the focused control (just like a tap with touch or a click with a mouse).

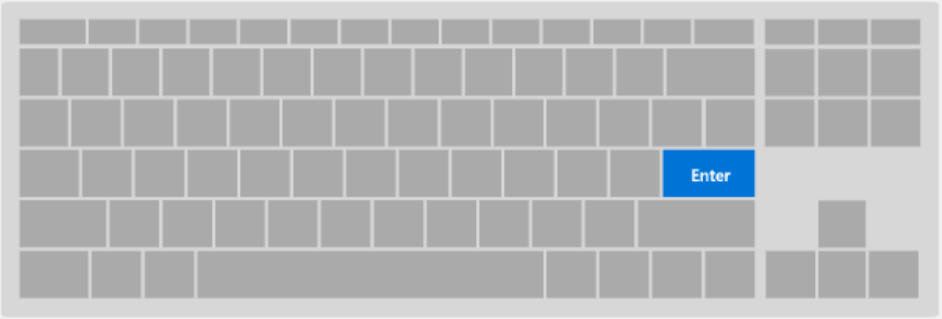


Enter key

The **Enter** key can perform a variety of common user interactions, depending on the control with focus:

- Activates command controls such as a `Button` or `Hyperlink`. To avoid end user confusion, the **Enter** key also activates controls that look like command controls such as `ToggleButton` or `AppBarToggleButton`.
- Displays the picker UI for controls such as `ComboBox` and `DatePicker`. The **Enter** key also commits and closes the picker UI.
- Activates list controls such as `ListView`, `GridView`, and `ComboBox`.
  - The **Enter** key performs the selection action as the **Space** key for list and grid items, unless there is an additional action associated with these items (opening a new window).
  - If an additional action is associated with the control, the **Enter** key performs the additional action and the **Space** key performs the selection action.

NOTE The **Enter** key and **Space** key do not always perform the same action, but often do.

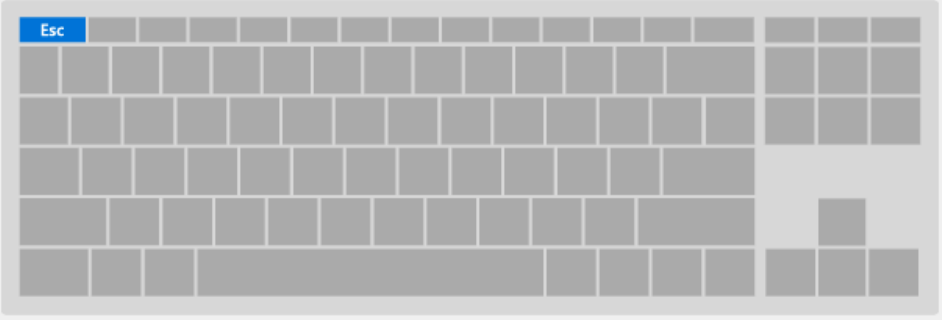


Esc key

The Esc key lets a user cancel transient UI (along with any ongoing actions in that UI).

Examples of this experience include:

- User opens a `ComboBox` with a selected value and uses the arrow keys to move the focus selection to a new value. Pressing the Esc key closes the `ComboBox` and resets the selected value back to the original value.
- User invokes a permanent delete action for an email and is prompted with a `ContentDialog` to confirm the action. The user decides this is not the intended action and presses the **Esc** key to close the dialog. As the **Esc** key is associated with the **Cancel** button, the dialog is closed and the action is canceled. The **Esc** key only affects transient UI, it does not close, or back navigate through, app UI.

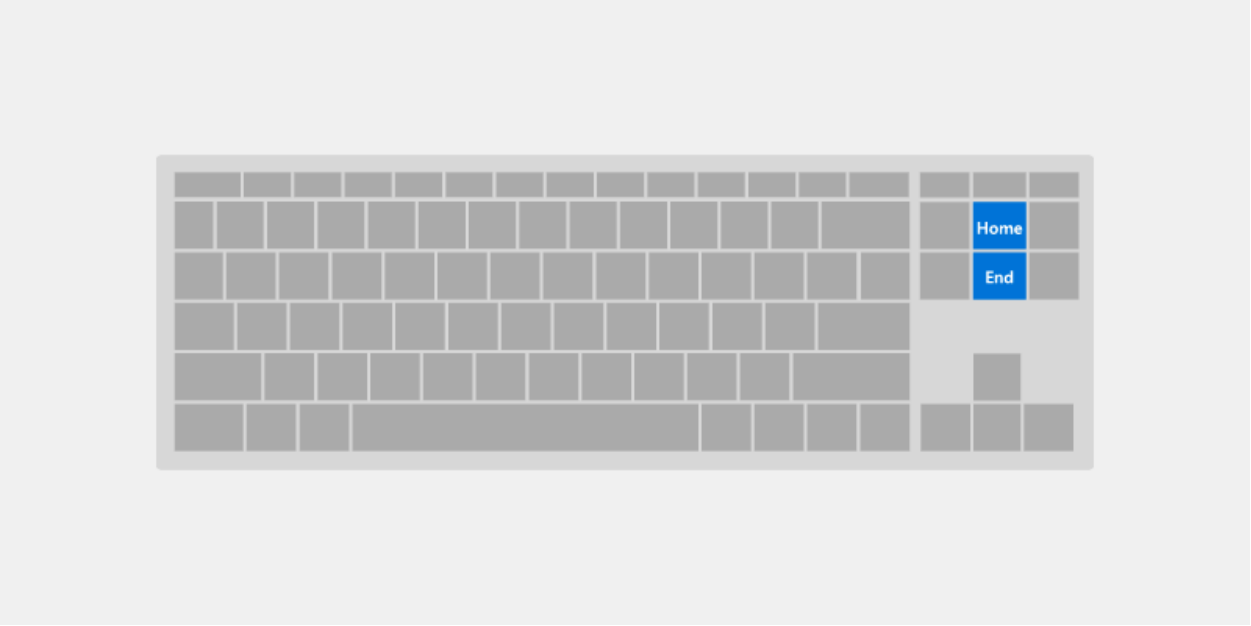


Home and End keys

The **Home** and **End** keys let a user scroll to the beginning or end of a UI region.

Examples of this experience include:

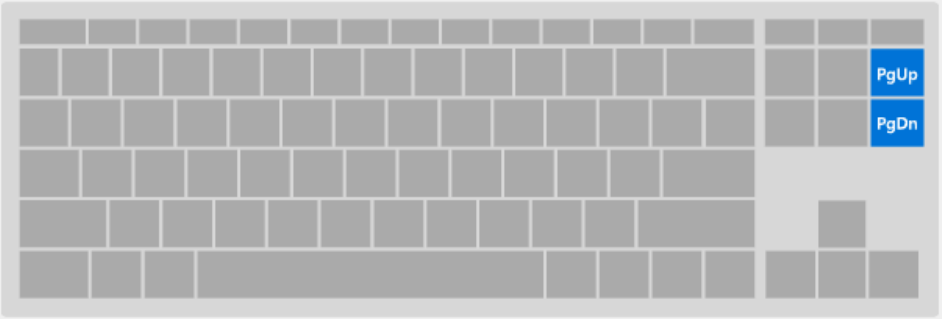
- For `ListView` and `GridView` controls, the **Home** key moves focus to the first element and scrolls it into view, whereas the **End** key moves focus to the last element and scrolls it into view.
- For a `ScrollView` control, the **Home** key scrolls to the top of the region, whereas the **End** key scrolls to the bottom of the region (focus is not changed).



Page up and Page down keys

The **Page** keys let a user scroll a UI region in discrete increments.

For example, for `ListView` and `GridView` controls, the **Page up** key scrolls the region up by a "page" (typically the viewport height) and moves focus to the top of the region. Alternately, the **Page down** key scrolls the region down by a page and moves focus to the bottom of the region.



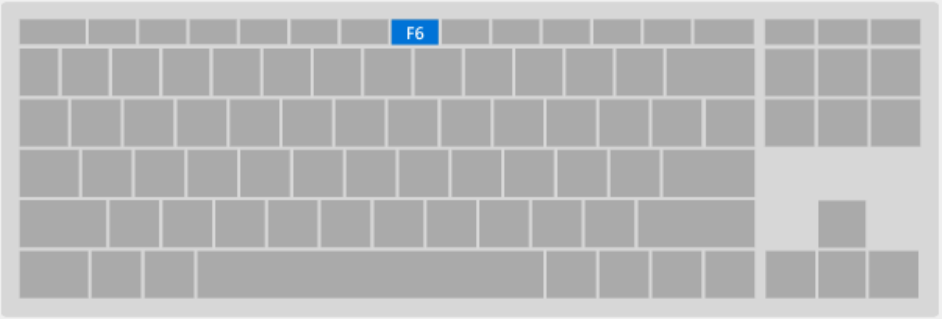
F6 key

The **F6** key lets a user cycle between panes or important sections of your app or UI. **Shift-F6** typically cycles backwards (see Keyboard accessibility).

These are often related to landmarks and headings, but do not need to correspond directly.

For example:

- In Edge, pressing F6 will cycle between the tab bar, the address bar/app bar, and the page content.
- In File Explorer, pressing F6 will cycle between the sections of the app.
- On the desktop, pressing F6 will cycle between parts of the taskbar and the desktop.



Keyboard shortcuts

In addition to implementing keyboard navigation and activation, it is also good practice to implement keyboard shortcuts such as keyboard accelerators and access keys for important or frequently used functionality.

Keyboard shortcuts can make your app easier to use by providing both enhanced support for accessibility and improved efficiency for keyboard users.

A shortcut is a keyboard combination that enhances productivity by providing an efficient way for the user to access app functionality. There are two kinds of shortcut:

- Accelerators are shortcuts that invoke an app command. Your app may or may not provide specific UI that corresponds to the command. Accelerators typically consist of the Ctrl key plus a letter key.
- Access keys are shortcuts that set focus to specific UI in your application. Access keys typically consist of the Alt key plus a letter key.

Providing consistent keyboard shortcuts that support similar tasks across applications makes them much more useful and powerful and helps users remember them.

Accelerators

Accelerators help users perform common actions in an application much more quickly and efficiently.

Examples of Accelerators:

- Pressing Ctrl + N key anywhere in the **Mail** app launches a new mail item.
- Pressing Ctrl + E key anywhere in Microsoft Edge (and many Microsoft Store applications) launches search.

Accelerators have the following characteristics:

- They primarily use Ctrl and Function key sequences (Windows system shortcut keys also use Alt + non-alphanumeric keys and the Windows logo key).
- They are assigned only to the most commonly used commands.
- They are intended to be memorized, and are documented only in menus, tooltips, and Help.
- They have effect throughout the entire application, when supported.
- They should be assigned consistently as they are memorized and not directly documented.

Access keys

See Access keys page for more in-depth information for supporting access keys with UWP.

Access keys help users with motor function disabilities an ability to press one key at a time to action on a specific item in the UI. Moreover, access keys can be used to communicate additional shortcut keys to help advanced users perform actions quickly.

Access keys have the following characteristics:

- They use the Alt key plus an alphanumeric key.
- They are primarily for accessibility.
- They are documented directly in the UI, adjacent to the control, through Key Tips.
- They have effect only in the current window, and navigate to the corresponding menu item or control.
- Access keys should be assigned consistently to commonly used commands (especially commit buttons), whenever possible.
- They are localized.

Common keyboard shortcuts

The following table is a small sample of frequently used keyboard shortcuts.

Expand table

Action	Key command
Select all	Ctrl+A
Continuously select	Shift+Arrow key
Save	Ctrl+S
Find	Ctrl+F
Print	Ctrl+P
Copy	Ctrl+C
Cut	Ctrl+X
Paste	Ctrl+V
Undo	Ctrl+Z
Next tab	Ctrl+Tab

Action	Key command
Close tab	Ctrl+F4 or Ctrl+W
Semantic zoom	Ctrl++ or Ctrl+-

For a comprehensive list of Windows system shortcuts, see keyboard shortcuts for Windows. For common application shortcuts, see keyboard shortcuts for Microsoft applications.

Advanced experiences

In this section, we discuss some of the more complex keyboard interaction experiences supported by UWP apps, along with some of the behaviors you should be aware of when your app is used on different devices and with different tools.

Control group

You can group a set of related, or complementary, controls in a "control group" (or directional area), which enables "inner navigation" using the arrow keys. The control group can be a single tab stop, or you can specify multiple tab stops within the control group.

Arrow key navigation

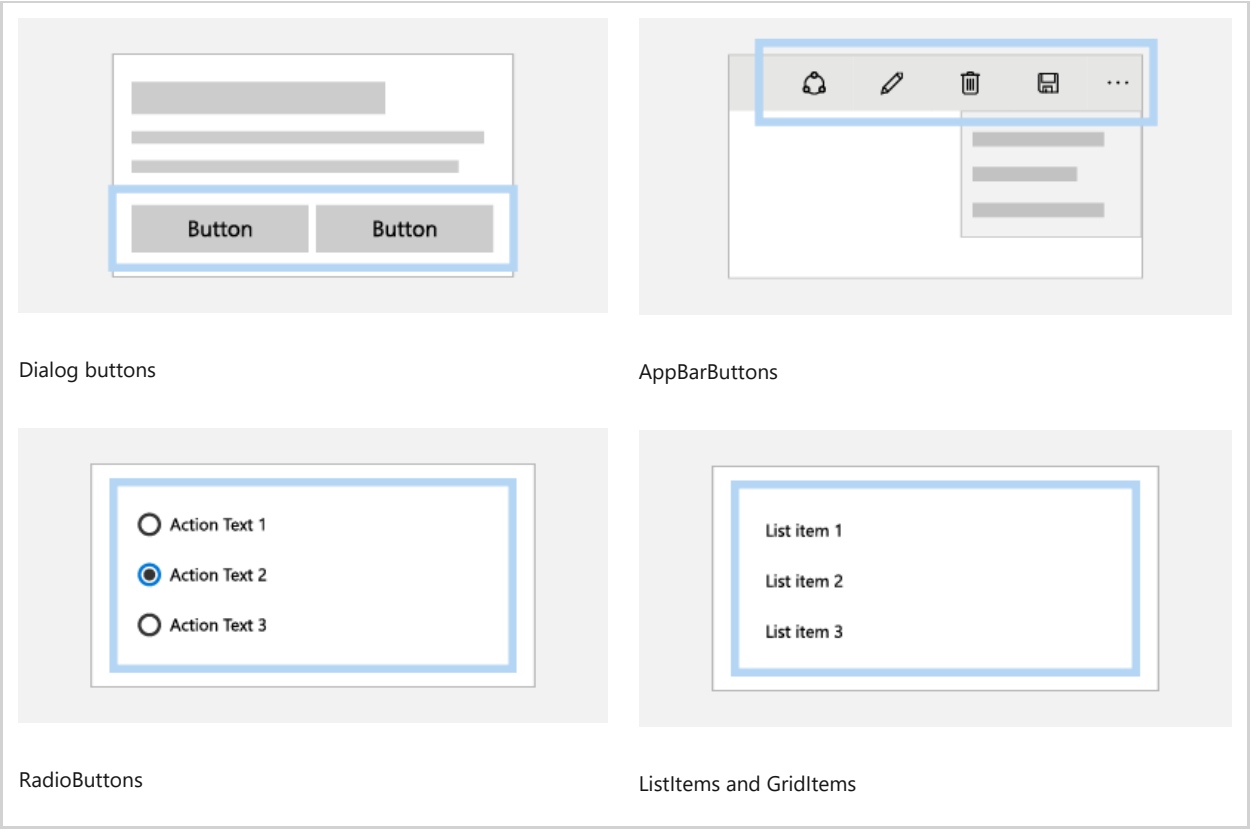
Users expect support for arrow key navigation when there is a group of similar, related controls in a UI region:

- `AppBarButtons` in a `CommandBar`
- `ListItems` or `GridItems` inside `ListView` or `GridView`
- `Buttons` inside `ContentDialog`

UWP controls support arrow key navigation by default. For custom layouts and control groups, use `XYFocusKeyboardNavigation="Enabled"` to provide similar behavior.

Consider adding support for arrow key navigation when using the following controls:

Expand table



Tab stops

Depending on your application's functionality and layout, the best navigation option for a control group might be a single tab stop with arrow navigation to child elements, multiple tab stops, or some combination.

Use multiple tab stops and arrow keys for buttons

Accessibility users rely on well-established keyboard navigation rules, which do not typically use arrow keys to navigate a collection of buttons. However, users without visual impairments might feel that the behavior is natural.

An example of default UWP behavior in this case is the `ContentDialog`. While arrow keys can be used to navigate between buttons, each button is also a tab stop.

Assign single tab stop to familiar UI patterns

In cases where your layout follows a well-known UI pattern for control groups, assigning a single tab stop to the group can improve navigation efficiency for users.

Examples include:

- `RadioButtons`
- Multiple `ListViews` that look like and behave like a single `ListView`

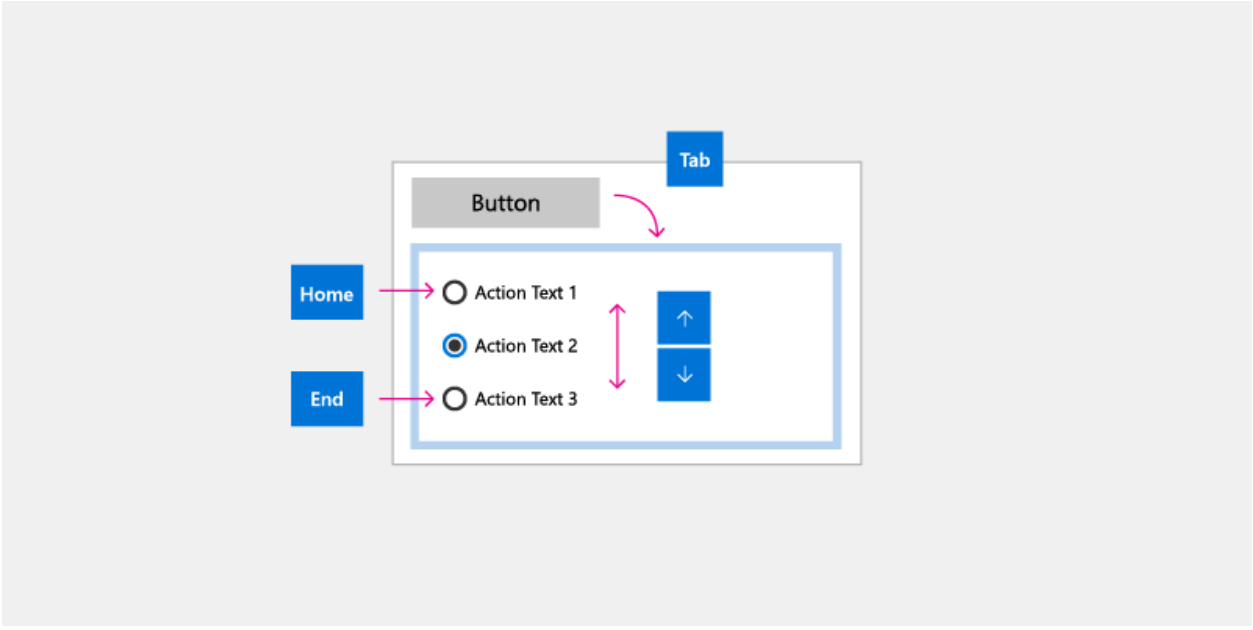
- Any UI made to look and behave like grid of tiles (such as the Start menu tiles)

Specifying control group behavior

Use the following APIs to support custom control group behavior (all are discussed in more detail later in this topic):

- XYFocusKeyboardNavigation enables arrow key navigation between controls
- TabFocusNavigation indicates whether there are multiple tab stops or single tab stop
- FindFirstFocusableElement and FindLastFocusableElement sets focus on the first item with **Home** key and the last item with **End** key

The following image shows an intuitive keyboard navigation behavior for a control group of associated radio buttons. In this case, we recommend a single tab stop for the control group, inner navigation between the radio buttons using the arrow keys, **Home** key bound to the first radio button, and **End** key bound to the last radio button.



Keyboard and Narrator

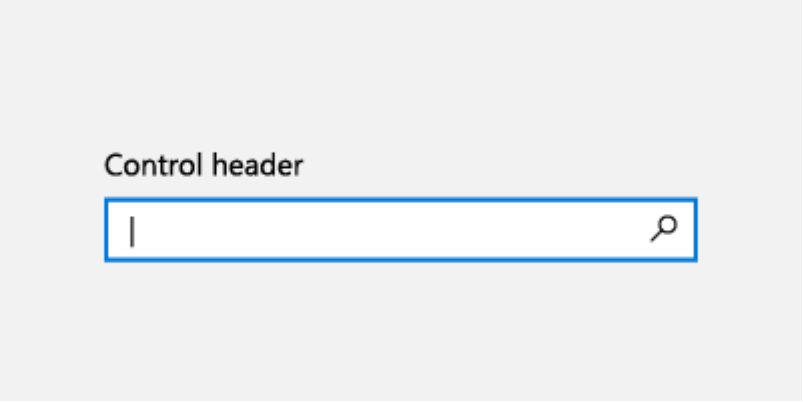
Narrator is a UI accessibility tool geared towards keyboard users (other input types are also supported). However, Narrator functionality goes beyond the keyboard interactions supported by UWP apps and extra care is required when designing your UWP app for Narrator. (The Narrator basics page guides you through the Narrator user experience.)

Some of the differences between UWP keyboard behaviors and those supported by Narrator include:

- Extra key combinations for navigation to UI elements that are not exposed through standard keyboard navigation, such as Caps lock + arrow keys to read control labels.
- Navigation to disabled items. By default, disabled items are not exposed through standard keyboard navigation.
- Control "views" for quicker navigation based on UI granularity. Users can navigate to items, characters, word, lines, paragraphs, links, headings, tables, landmarks, and suggestions. Standard keyboard navigation exposes these objects as a flat list, which might make navigation cumbersome unless you provide shortcut keys.

Case Study – AutoSuggestBox control

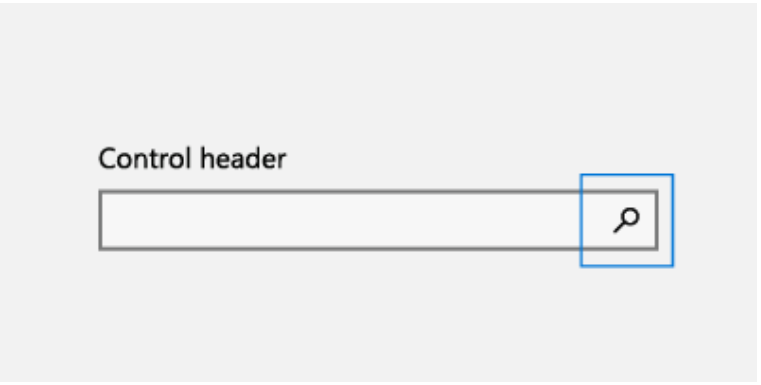
The search button for the `AutoSuggestBox` is not accessible to standard keyboard navigation using tab and arrow keys because the user can press the **Enter** key to submit the search query. However, it is accessible through Narrator when the user presses Caps Lock + an arrow key.



*With keyboard, users press the **Enter** key to submit search query*

Expand table

*With Narrator, users press the **Enter** key to submit search query*



*With Narrator, users are also able to access the search button using the **Caps Lock + Right arrow key**, then pressing **Space** key*

Keyboard, game pad, and remote control

Game pads and remote controls support many UWP keyboard behaviors and experiences. However, due to the lack of various key options available on a keyboard, game pad and remote control lack many keyboard optimizations (remote control is even more limited than game pad).

See Game pad and remote control interactions for more detail on UWP support for game pad and remote control input.

The following shows some key mappings between keyboard, game pad, and remote control.

Expand table

Keyboard	Game pad	Remote control
Space	A button	Select button
Enter	A button	Select button
Escape	B button	Back button
Home/End	N/A	N/A
Page Up/Down	Trigger button for vertical scroll, Bumper button for horizontal scroll	N/A

Some key differences you should be aware of when designing your UWP app for use with game pad and remote control usage include:

- Text entry requires the user to press A to activate a text control.
- Focus navigation is not limited to control groups, users can navigate freely to any focusable UI element in the app.

  NOTE Focus can move to any focusable UI element in the key press direction unless it is in an overlay UI or focus engagement is specified, which prevents focus from entering/exiting a region until engaged/disengaged with the A button. For more info, see the directional navigation section.

- D-pad and left stick buttons are used to move focus between controls and for inner navigation.

  NOTE Gamepad and remote control only navigate to items that are in the same visual order as the directional key pressed. Navigation is disabled in that direction

when there is no subsequent element that can receive focus. Depending on the situation, keyboard users do not always have that constraint. See the Built in keyboard optimization section for more info.

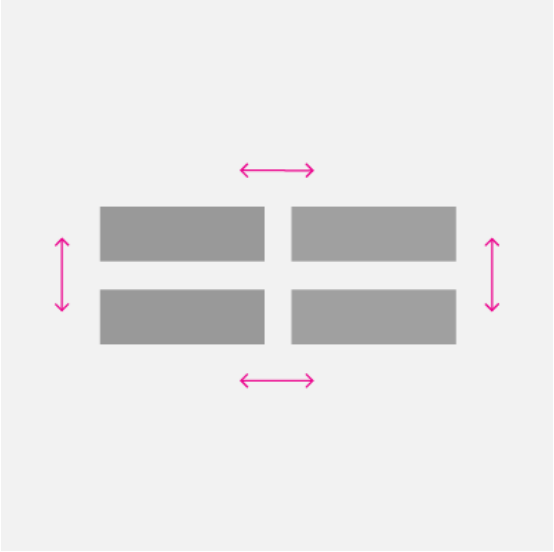
Directional navigation

Directional navigation is managed by a UWP Focus Manager helper class, which takes the directional key pressed (arrow key, D-pad) and attempts to move focus in the corresponding visual direction.

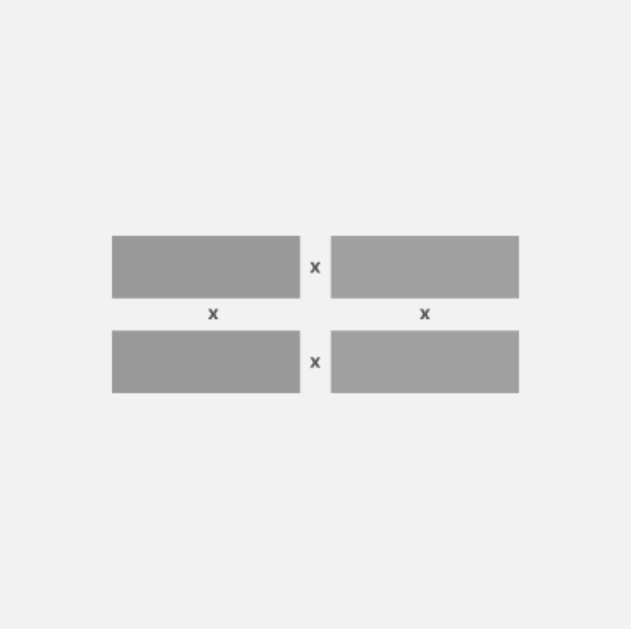
Unlike the keyboard, when an app opts out of Mouse Mode, directional navigation is applied across the entire application for gamepad and remote control. See Gamepad and remote control interactions for more detail on directional navigation optimization.

NOTE Navigation using the keyboard Tab key is not considered directional navigation. For more info, see the Tab stops section.

Expand table



Directional navigation supported
Using directional keys (keyboard arrows, gamepad and remote control D-pad), user can navigate between different controls.



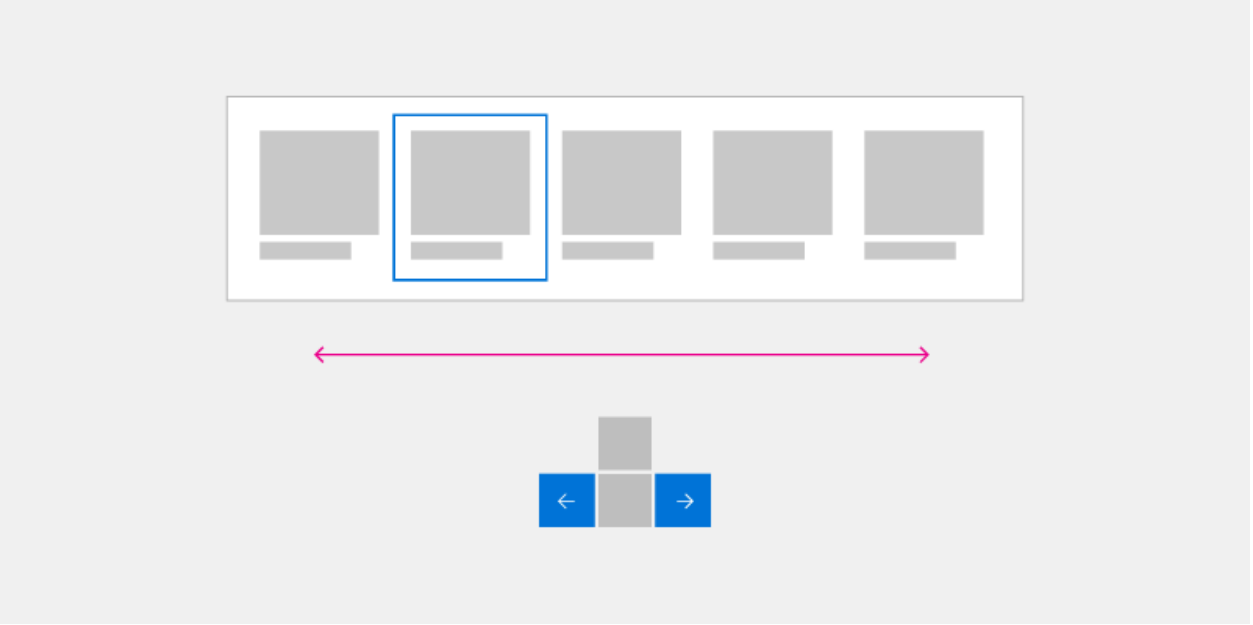
Directional navigation not supported
User cannot navigate between different controls using directional keys. Other methods of navigating between controls (tab key) are not impacted.

Built in keyboard optimization

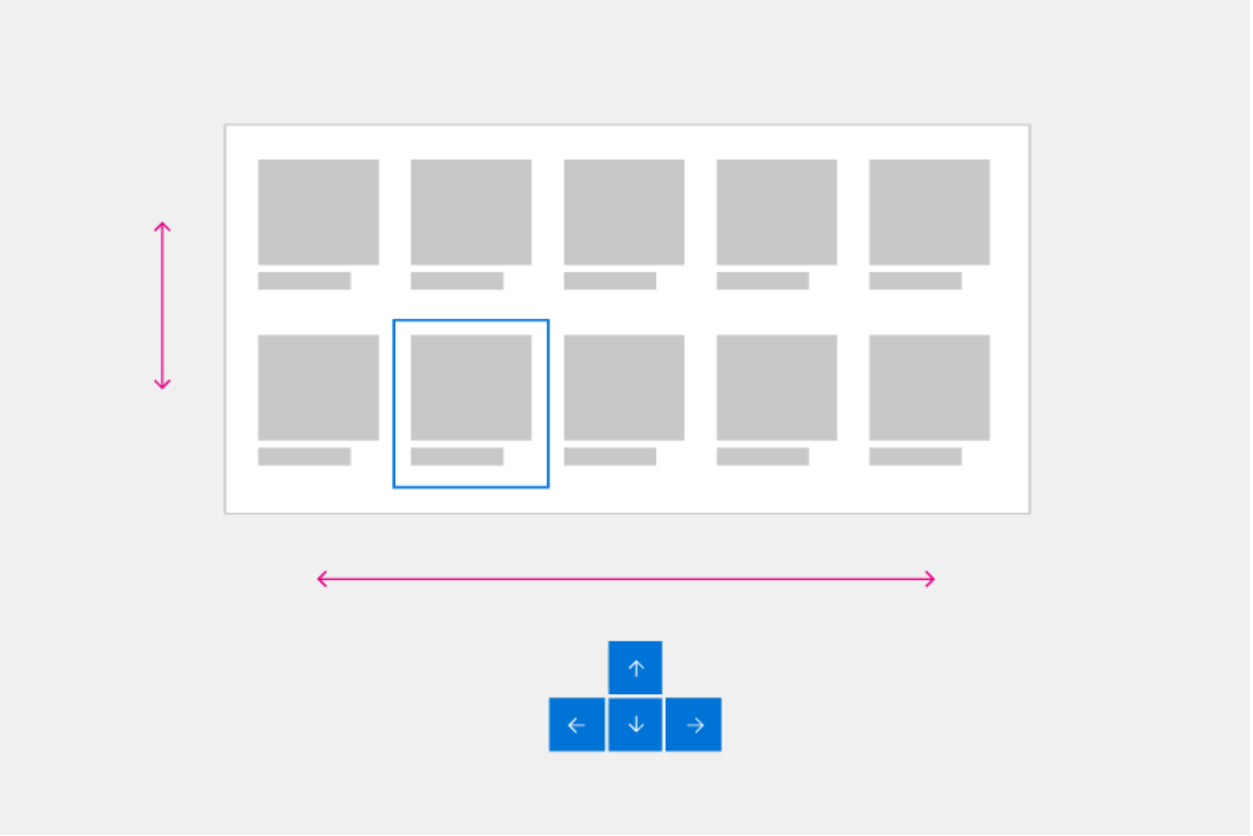
Depending on the layout and controls used, UWP apps can be optimized specifically for keyboard input.

The following example shows a group of list items, grid items, and menu items that have been assigned to a single tab stop (see the Tab stops section). When the group has focus, inner navigation is performed with the directional arrow keys in the corresponding visual order (see Navigation section).

Single Column Arrow Key Navigation



Single Row Arrow Key Navigation



Multiple Column/Row Arrow Key Navigation

Wrapping homogeneous List and Grid View Items

Directional navigation is not always the most efficient way to navigate multiple rows and columns of List and GridView items.

NOTE Menu items are typically single column lists, but special focus rules might apply in some cases (see Popup UI).

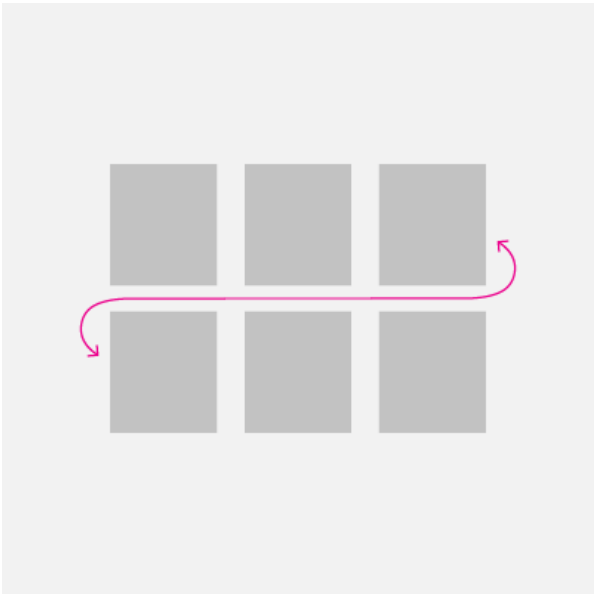
List and Grid objects can be created with multiple rows and columns. These are typically in row-major (where items fill entire row first before filling in the next row) or column-major (where items fill entire column first before filling in the next column) order. Row or column major order depends on scroll direction and you should ensure that item order does not conflict with this direction.

In row-major order (where items fill in left to right, top to bottom), when the focus is on the last item in a row and the Right arrow key is pressed, focus is moved to the first item in the next row. This same behavior occurs in reverse: When focus is set to the first item in a row and the Left arrow key is pressed, focus is moved to the last item in the previous row.

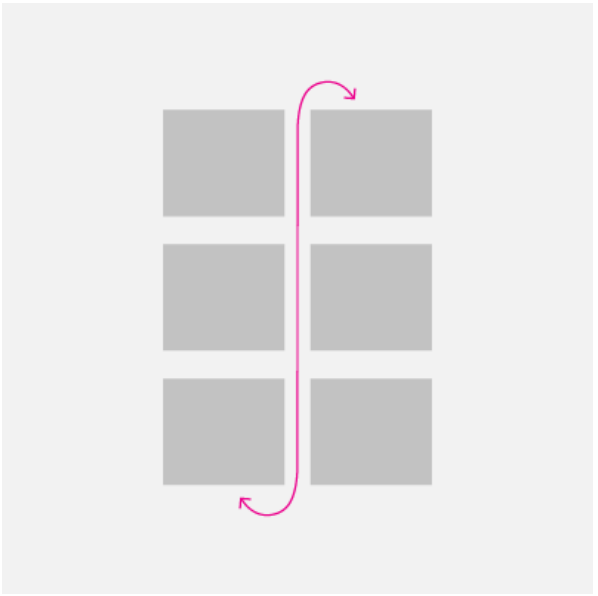
In column-major order (where items fill in top to bottom, left to right), when the focus is on the last item in a column and user presses the Down arrow key, focus is moved to the first item in the next column. This same behavior occurs in reverse: When focus is set

to the first item in a column and the Up arrow key is pressed, focus is moved to the last item in the previous column.

Expand table



Row major keyboard navigation



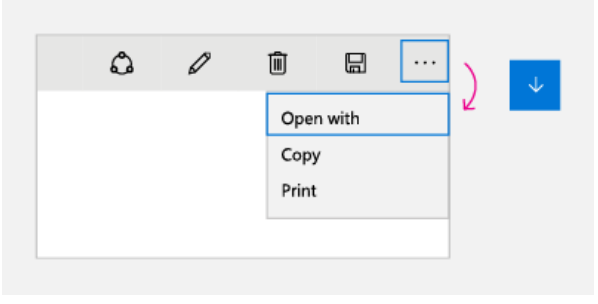
Column major keyboard navigation

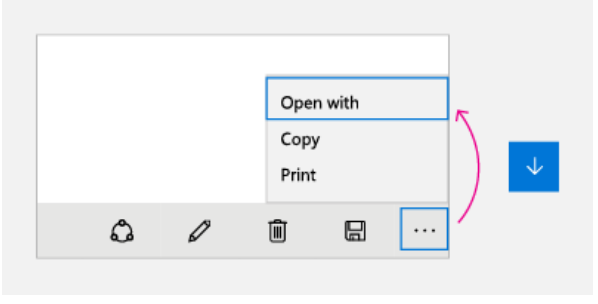
Popup UI

As mentioned, you should try to ensure directional navigation corresponds to the visual order of the controls in your application's UI.

Some controls (such as the context menu, CommandBar overflow menu, and AutoSuggest menu) display a menu popup in a location and direction (downwards by default) relative to the primary control and available screen space. Note that the opening direction can be affected by a variety of factors at run time.

Expand table





For these controls, when the menu is first opened (and no item has been selected by the user), the Down arrow key always sets focus to the first item while the Up arrow key always sets focus to the last item on the menu.

If the last item has focus and the Down arrow key is pressed, focus moves to the first item on the menu. Similarly, if the first item has focus and the Up arrow key is pressed, focus moves to the last item on the menu. This behavior is referred to as *cycling* and is useful for navigating popup menus that can open in unpredictable directions.

> **Note**
>
> Cycling should be avoided in non-popup UIs where users might come to feel trapped in an endless loop.

We recommend that you emulate these same behaviors in your custom controls. Code sample on how to implement this behavior can be found in Programmatic focus navigation documentation.

Test your app

Test your app with all supported input devices to ensure UI elements can be navigated to in a coherent and intuitive way and that no unexpected elements interfere with the desired tab order.

Appendix

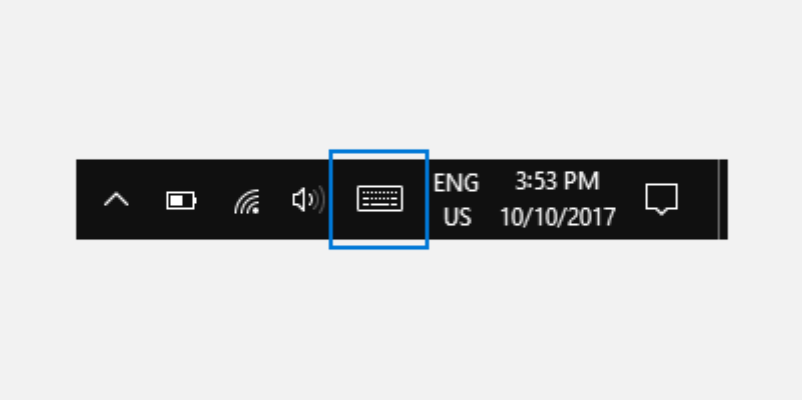
Software keyboard

A software keyboard is displayed on screen and used instead of the physical keyboard to type and enter data using touch, mouse, pen/stylus or other pointing device. On gaming devices, individual keys need to be selected by moving focus visual or using shortcut keys on a game pad or remote control.

Touch keyboard

Windows 11 Touch Keyboard

Depending on the device, the touch keyboard appears when a text field or other editable text control gets focus, or when the user manually enables it through the **Notification Center**:



If your app sets focus programmatically to a text input control, the touch keyboard is not invoked. This eliminates unexpected behaviors not instigated directly by the user. However, the keyboard does automatically hide when focus is moved programmatically to a non-text input control.

The touch keyboard typically remains visible while the user navigates between controls in a form. This behavior can vary based on the other control types within the form.

The following is a list of non-edit controls that can receive focus during a text entry session using the touch keyboard without dismissing the keyboard. Rather than needlessly churn the UI and potentially disorient the user, the touch keyboard remains in view because the user is likely to go back and forth between these controls and text entry with the touch keyboard.

- Check box
- Combo box
- Radio button
- Scroll bar
- Tree
- Tree item
- Menu
- Menu bar
- Menu item
- Toolbar
- List
- List item

Here are examples of different modes for the touch keyboard. The first image is the default layout, the second is the expanded layout (which might not be available in all languages).

The touch keyboard in default layout mode

The touch keyboard in expanded layout mode

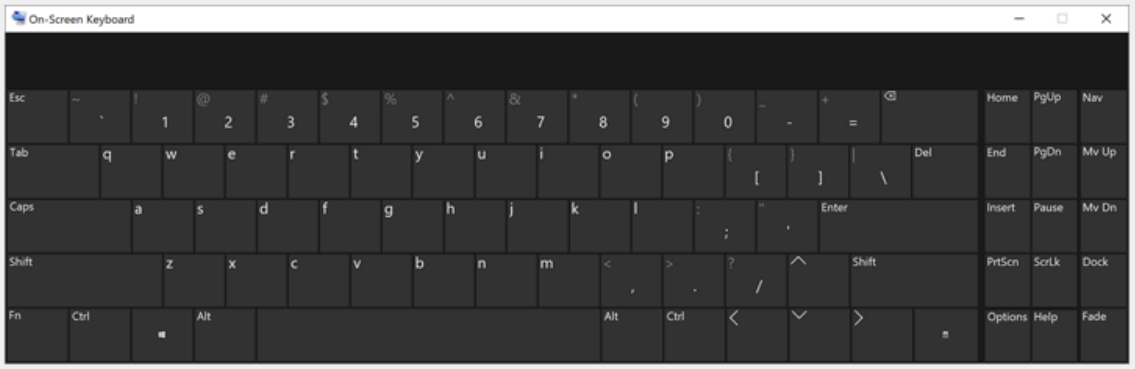
Successful keyboard interactions enable users to accomplish basic app scenarios using only the keyboard; that is, users can reach all interactive elements and activate default functionality. A number of factors can affect the degree of success, including keyboard navigation, access keys for accessibility, and accelerator (or shortcut) keys for advanced users.

On-Screen Keyboard

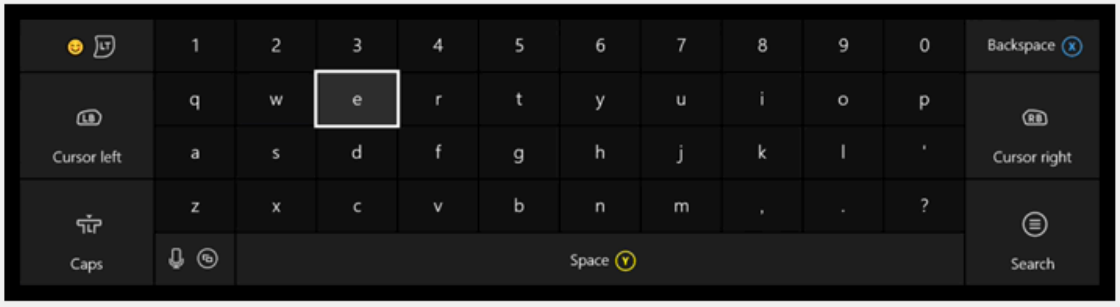
Like the touch keyboard, the On-Screen Keyboard (OSK) is a visual, software keyboard used instead of the physical keyboard to type and enter data using touch, mouse, pen/stylus or other pointing device (a touch screen is not required). The OSK is provided for systems that don't have a physical keyboard, or for users whose mobility impairments prevent them from using traditional physical input devices. The OSK emulates most, if not all, the functionality of a hardware keyboard.

The OSK can be turned on from the Keyboard page in Settings > Ease of access.

NOTE The OSK has priority over the touch keyboard, which won't be shown if the OSK is present.



On-Screen Keyboard



Xbox One On-Screen Keyboard

Access keys

Article • 06/11/2024

Access keys are keyboard shortcuts that improve the usability and the accessibility of your Windows applications by providing an intuitive way for users to quickly navigate and interact with an app's visible UI through a keyboard instead of a pointer device (such as touch or mouse).

The Windows app provides built-in support across platform controls for both keyboard-based access keys and associated UI feedback through visual cues called keytips.

> **Note**
>
> A keyboard is indispensable for users with certain disabilities (see Keyboard accessibility), and is also an important tool for users who prefer it as a more efficient way to interact with an app.

See the Accelerator keys topic for details on invoking common actions in a Windows application with keyboard shortcuts.

To create your own custom keyboard shortcuts, see the Keyboard events topic.

Overview

An access key is a combination of the Alt key and one or more alphanumeric keys—sometimes called a *mnemonic*—typically pressed sequentially, rather than simultaneously.

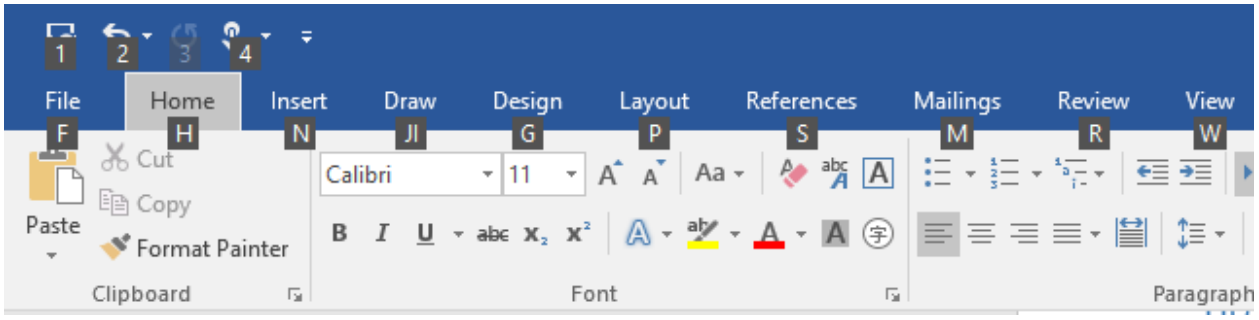
Keytips are badges displayed next to controls that support access keys when the user presses the Alt key. Each keytip contains the alphanumeric keys that activate the associated control.

> **Note**
>
> Keyboard shortcuts are automatically supported for access keys with a single alphanumeric character. For example, simultaneously pressing Alt+F in Word opens the File menu without displaying keytips.

Pressing the Alt key initializes access key functionality and displays all currently available key combinations in keytips. Subsequent keystrokes are handled by the access key

framework, which rejects invalid keys until either a valid access key is pressed, or the Enter, Esc, Tab, or Arrow keys are pressed to deactivate access keys and return keystroke handling to the app.

Microsoft Office apps provide extensive support for access keys. The following image shows the Home tab of Word with access keys activated (note the support for both numbers and multiple keystrokes).



KeyTip badges for access keys in Microsoft Word

To add an access key to a control, use the **AccessKey property**. The value of this property specifies the access key sequence, the shortcut (if a single alphanumeric), and the keytip.

XAML

```
<Button Content="Accept" AccessKey="A" Click="AcceptButtonClick" />
```

When to use access keys

We recommend that you specify access keys wherever appropriate in your UI, and support access keys in all custom controls.

1. **Access keys make your app more accessible** for users with motor disabilities, including those users who can press only one key at a time or have difficulty using a mouse.

   A well-designed keyboard UI is an important aspect of software accessibility. It enables users with vision impairments or who have certain motor disabilities to navigate an app and interact with its features. Such users might not be able to operate a mouse and instead rely on various assistive technologies such as keyboard enhancement tools, on-screen keyboards, screen enlargers, screen readers, and voice input utilities. For these users, comprehensive command coverage is crucial.

2. **Access keys make your app more usable** for power users who prefer to interact through the keyboard.

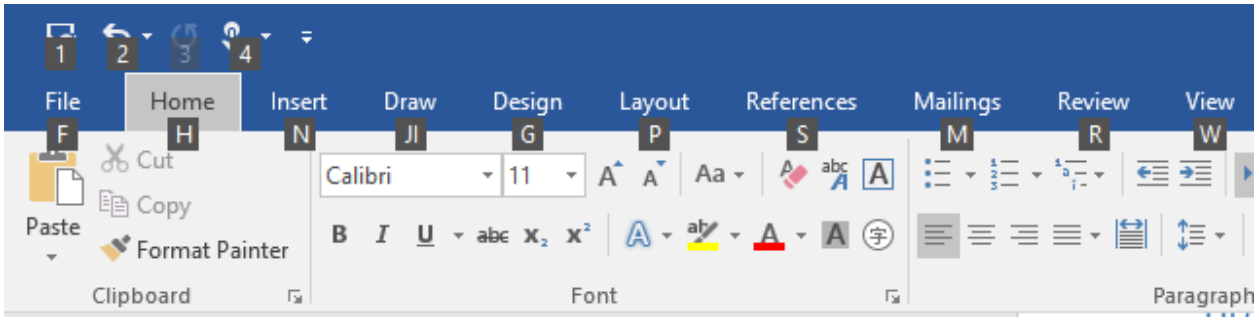
   Experienced users often have a strong preference for using the keyboard because keyboard-based commands can be entered more quickly and don't require them to remove their hands from the keyboard. For these users, efficiency and consistency are crucial; comprehensiveness is important only for the most frequently used commands.

Set access key scope

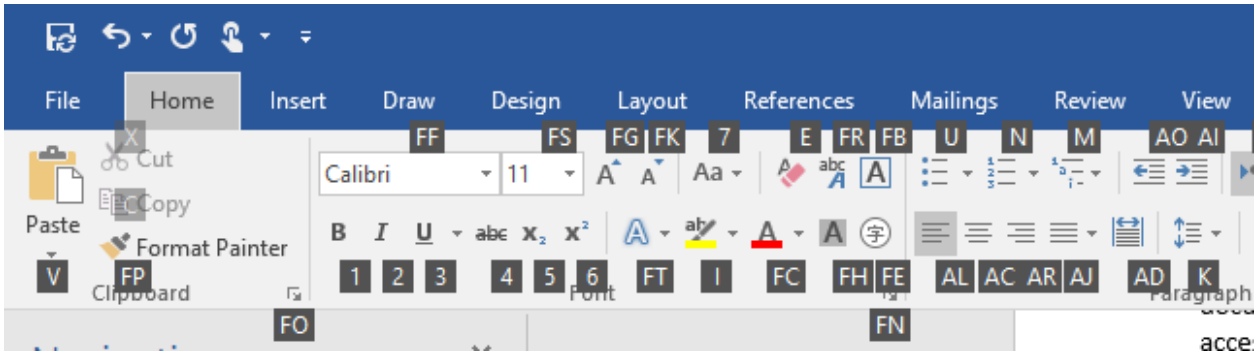
When there are many elements on the screen that support access keys, we recommend scoping the access keys to reduce **cognitive load**. This minimizes the number of access keys on the screen, which makes them easier to locate, and improves efficiency and productivity.

For example, Microsoft Word provides two access key scopes: a primary scope for the Ribbon tabs and a secondary scope for commands on the selected tab.

The following images demonstrate the two access key scopes in Word. The first shows the primary access keys that let a user select a tab and other top level commands, and the second shows the secondary access keys for the Home tab.



Primary access keys in Microsoft Word



Secondary access keys in Microsoft Word

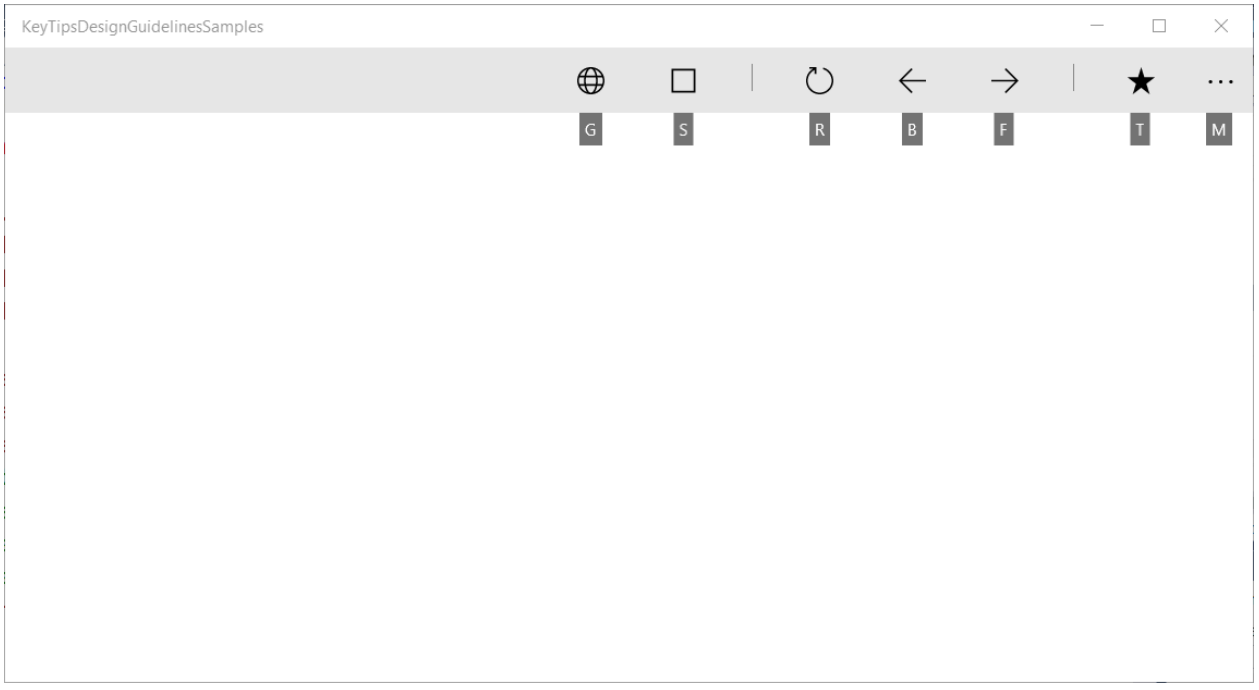
Access keys can be duplicated for elements in different scopes. In the preceding example, "2" is the access key for Undo in the primary scope, and also "Italics" in the

secondary scope.

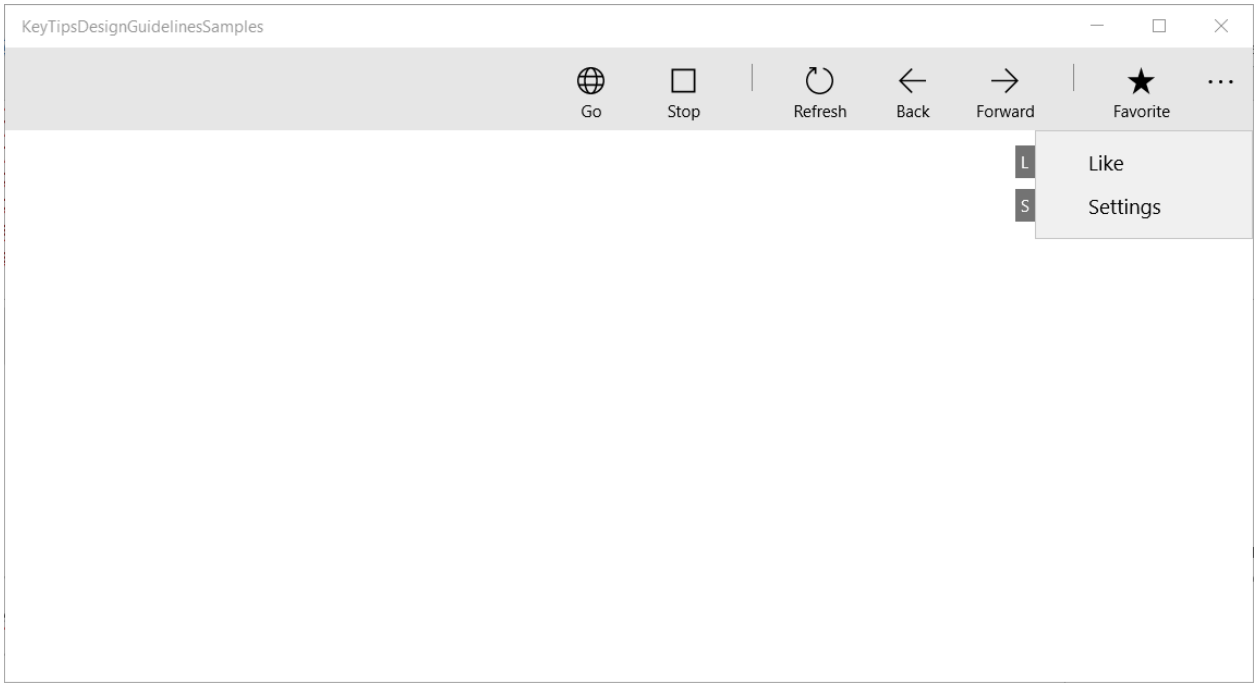
Here, we show how to define an access key scope.

XAML

```
<CommandBar x:Name="MainCommandBar" AccessKey="M" >
    <AppBarButton AccessKey="G" Icon="Globe" Label="Go"/>
    <AppBarButton AccessKey="S" Icon="Stop" Label="Stop"/>
    <AppBarSeparator/>
    <AppBarButton AccessKey="R" Icon="Refresh" Label="Refresh"
IsAccessKeyScope="True">
        <AppBarButton.Flyout>
            <MenuFlyout>
                <MenuFlyoutItem AccessKey="A" Icon="Globe" Text="Refresh A"
/>
                <MenuFlyoutItem AccessKey="B" Icon="Globe" Text="Refresh B"
/>
                <MenuFlyoutItem AccessKey="C" Icon="Globe" Text="Refresh C"
/>
                <MenuFlyoutItem AccessKey="D" Icon="Globe" Text="Refresh D"
/>
            </MenuFlyout>
        </AppBarButton.Flyout>
    </AppBarButton>
    <AppBarButton AccessKey="B" Icon="Back" Label="Back"/>
    <AppBarButton AccessKey="F" Icon="Forward" Label="Forward"/>
    <AppBarSeparator/>
    <AppBarToggleButton AccessKey="T" Icon="Favorite" Label="Favorite"/>
    <CommandBar.SecondaryCommands>
        <AppBarToggleButton Icon="Like" AccessKey="L" Label="Like"/>
        <AppBarButton Icon="Setting" AccessKey="S" Label="Settings" />
    </CommandBar.SecondaryCommands>
</CommandBar>
```



CommandBar primary scope and supported access keys



CommandBar secondary scope and supported access keys

Windows 10 Creators Update and older

Prior to Windows 10 Fall Creators Update, some controls, such as the CommandBar, didn't support built-in access key scopes.

The following example shows how to support CommandBar SecondaryCommands with access keys, which are available once a parent command is invoked (similar to the Ribbon in Word).

XAML

```
<local:CommandBarHack x:Name="MainCommandBar" AccessKey="M" >
    <AppBarButton AccessKey="G" Icon="Globe" Label="Go"/>
    <AppBarButton AccessKey="S" Icon="Stop" Label="Stop"/>
    <AppBarSeparator/>
    <AppBarButton AccessKey="R" Icon="Refresh" Label="Refresh"
IsAccessKeyScope="True">
        <AppBarButton.Flyout>
            <MenuFlyout>
                <MenuFlyoutItem AccessKey="A" Icon="Globe" Text="Refresh A"
/>
                <MenuFlyoutItem AccessKey="B" Icon="Globe" Text="Refresh B"
/>
                <MenuFlyoutItem AccessKey="C" Icon="Globe" Text="Refresh C"
/>
                <MenuFlyoutItem AccessKey="D" Icon="Globe" Text="Refresh D"
/>
            </MenuFlyout>
```

```
        </AppBarButton.Flyout>
    </AppBarButton>
    <AppBarButton AccessKey="B" Icon="Back" Label="Back"/>
    <AppBarButton AccessKey="F" Icon="Forward" Label="Forward"/>
    <AppBarSeparator/>
    <AppBarToggleButton AccessKey="T" Icon="Favorite" Label="Favorite"/>
    <CommandBar.SecondaryCommands>
        <AppBarToggleButton Icon="Like" AccessKey="L" Label="Like"/>
        <AppBarButton Icon="Setting" AccessKey="S" Label="Settings" />
    </CommandBar.SecondaryCommands>
</local:CommandBarHack>
```

C#

```
public class CommandBarHack : CommandBar
{
    CommandBarOverflowPresenter secondaryItemsControl;
    Popup overflowPopup;

    public CommandBarHack()
    {
        this.ExitDisplayModeOnAccessKeyInvoked = false;
        AccessKeyInvoked += OnAccessKeyInvoked;
    }

    protected override void OnApplyTemplate()
    {
        base.OnApplyTemplate();

        Button moreButton = GetTemplateChild("MoreButton") as Button;
        moreButton.SetValue(Control.IsTemplateKeyTipTargetProperty, true);
        moreButton.IsAccessKeyScope = true;

        // SecondaryItemsControl changes
        secondaryItemsControl = GetTemplateChild("SecondaryItemsControl") as
CommandBarOverflowPresenter;
        secondaryItemsControl.AccessKeyScopeOwner = moreButton;

        overflowPopup = GetTemplateChild("OverflowPopup") as Popup;
    }

    private void OnAccessKeyInvoked(UIElement sender,
AccessKeyInvokedEventArgs args)
    {
        if (overflowPopup != null)
        {
            overflowPopup.Opened += SecondaryMenuOpened;
        }
    }

    private void SecondaryMenuOpened(object sender, object e)
    {
        //This is not necessary given we are automatically pushing the
```

```
scope.
        var item = secondaryItemsControl.Items.First();
        if (item != null && item is Control)
        {
            (item as Control).Focus(FocusState.Keyboard);
        }
        overflowPopup.Opened -= SecondaryMenuOpened;
    }
}
```

Avoid access key collisions

Access key collisions occur when two or more elements in the same scope have duplicate access keys, or start with the same alphanumeric characters.

The system resolves duplicate access keys by processing the access key of the first element added to the visual tree, ignoring all others.

When multiple access keys start with the same character (for example, "A", "A1", and "AB"), the system processes the single character access key and ignores all others.

Avoid collisions by using unique access keys or by scoping commands.

Choose access keys

Consider the following when choosing access keys:

- Use a single character to minimize keystrokes and support accelerator keys by default (Alt+AccessKey)
- Avoid using more than two characters
- Avoid access keys collisions
- Avoid characters that are difficult to differentiate from other characters, such as the letter "I" and the number "1" or the letter "O" and the number "0"
- Use well-known precedents from other popular apps such as Word ("F" for "File", "H" for "Home", and so on)
- Use the first character of the command name, or a character with a close association to the command that helps with recall
  - If the first letter is already assigned, use a letter that is as close as possible to the first letter of the command name ("N" for Insert)
  - Use a distinctive consonant from the command name ("W" for View)
  - Use a vowel from the command name.

Localize access keys

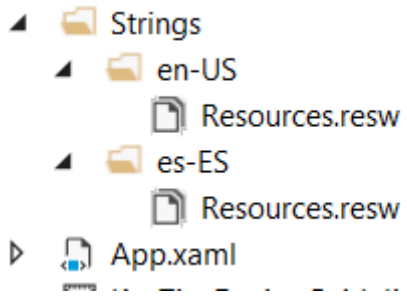
If your app is going to be localized in multiple languages, you should also **consider localizing the access keys**. For example, for "H" for "Home" in en-US and "I" for "Incio" in es-ES.

Use the x:Uid extension in markup to apply localized resources as shown here:

XAML

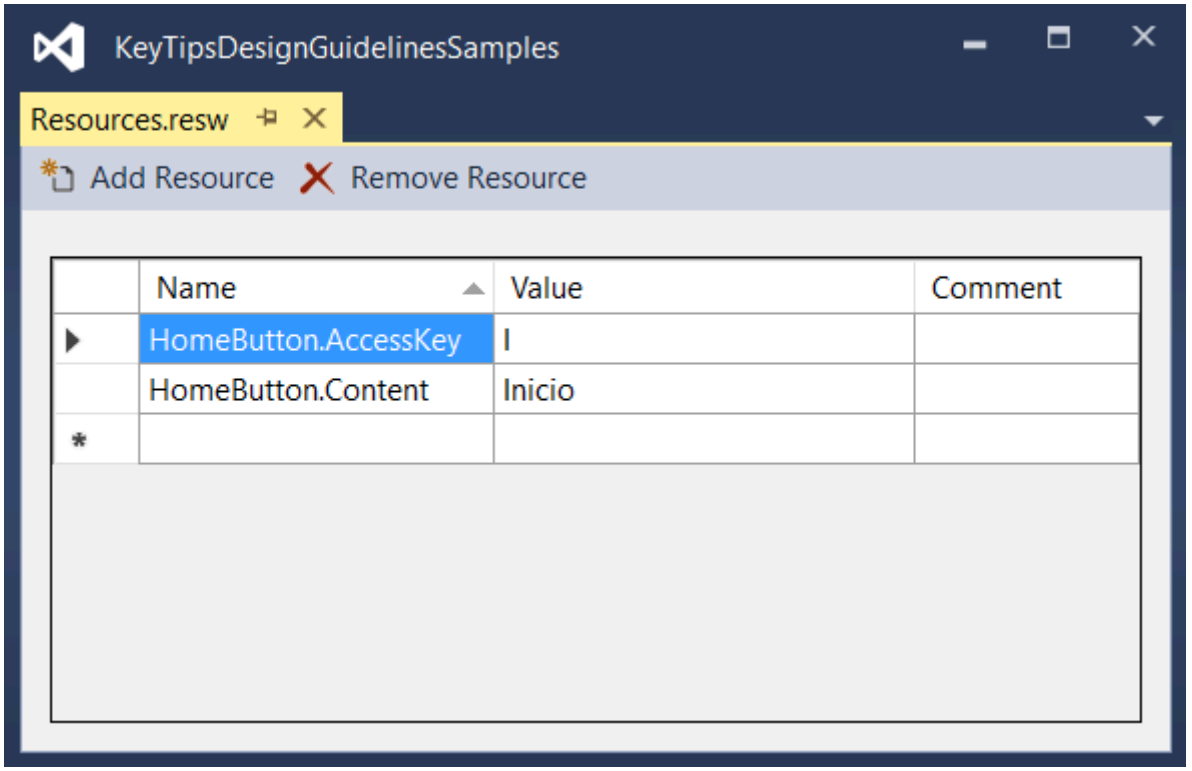
```
<Button Content="Home" AccessKey="H" x:Uid="HomeButton" />
```

Resources for each language are added to corresponding String folders in the project:



English and Spanish resource string folders

Localized access keys are specified in your projects resources.resw file:



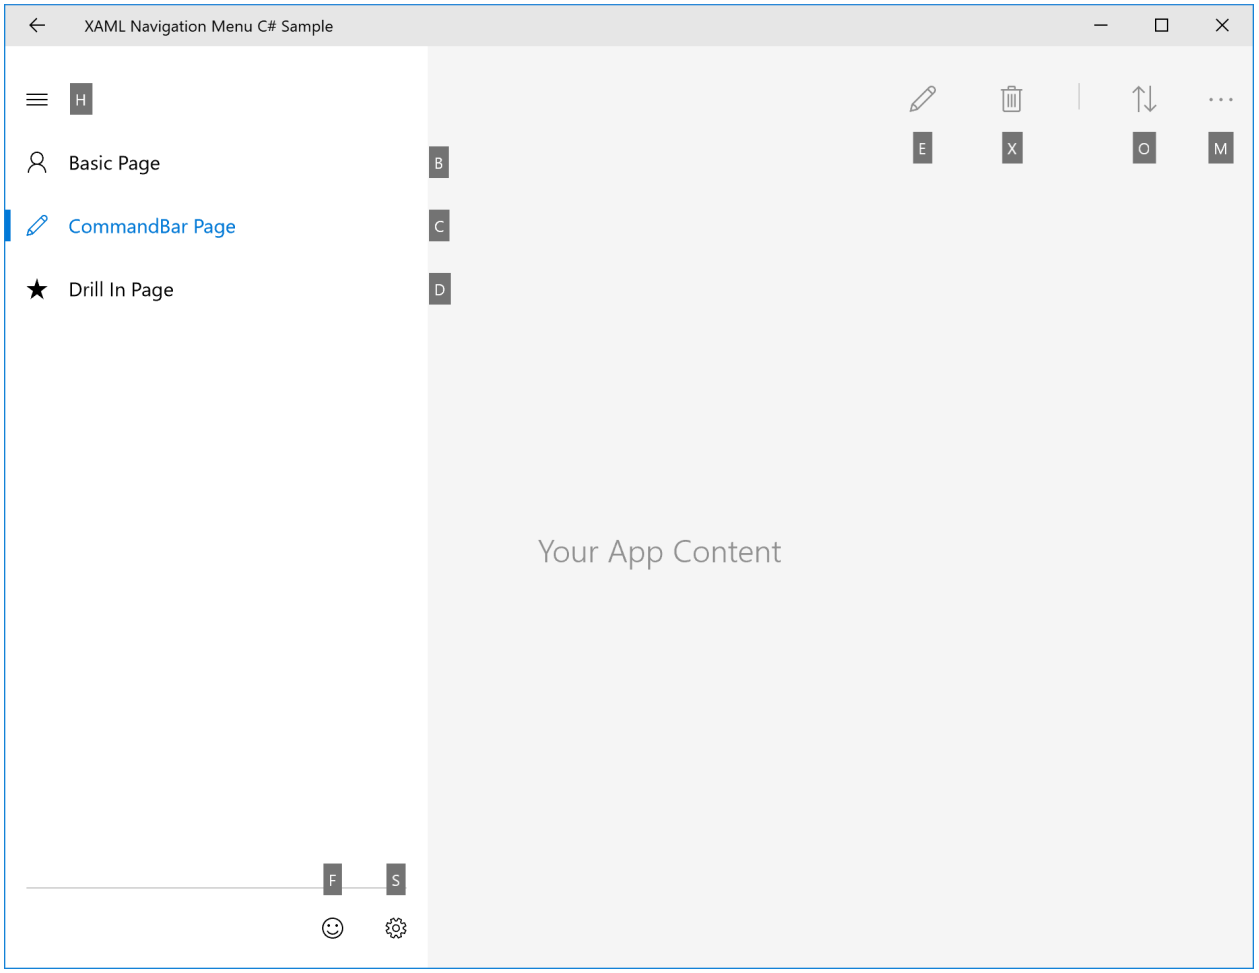
Specify the AccessKey property specified in the resources.resw file

For more info, see Translating UI resources

Keytip positioning

Keytips are displayed as floating badges relative to their corresponding UI element, taking into account the presence of other UI elements, other keytips, and the screen edge.

Typically, the default keytip location is sufficient and provides built-in support for adaptive UI.



Example of automatic keytip placement

However, should you need more control over keytip positioning, we recommend the following:

1. **Obvious association principle**: The user can associate the control with the keytip easily.

   a. The keytip should be **close** to the element who have the access key (the owner).
   b. The keytip should **avoid covering enabled elements** that have access keys.
   c. If a keytip can't be placed close to its owner, it should overlap the owner.

2. **Discoverability**: The user can discover the control with the keytip quickly.

    a. The keytip never **overlaps** other keytips.

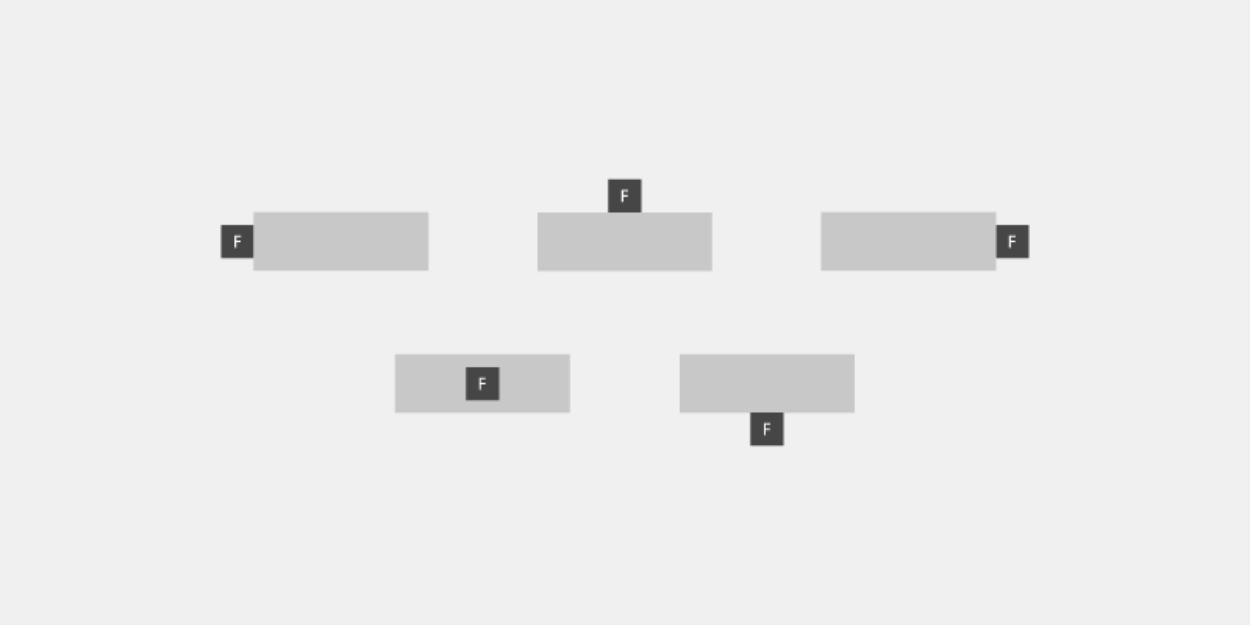
3. **Easy scanning:** The user can skim the keytips easily.

    a. keytips should be **aligned** with each other and with the UI Element. b. keytips should be **grouped** as much as possible.

Relative position

Use the **KeyTipPlacementMode** property to customize the placement of the keytip on a per element or per group basis.

The placement modes are: Top, Bottom, Right, Left, Hidden, Center, and Auto.



keytip placement modes

The center line of the control is used to calculate the vertical and horizontal alignment of the keytip.

They following example shows how to set the keytip placement of a group of controls using the KeyTipPlacementMode property of a StackPanel container.

XAML

```
<StackPanel Background="{ThemeResource ApplicationPageBackgroundThemeBrush}"
KeyTipPlacementMode="Top">
  <Button Content="File" AccessKey="F" />
  <Button Content="Home" AccessKey="H" />
```

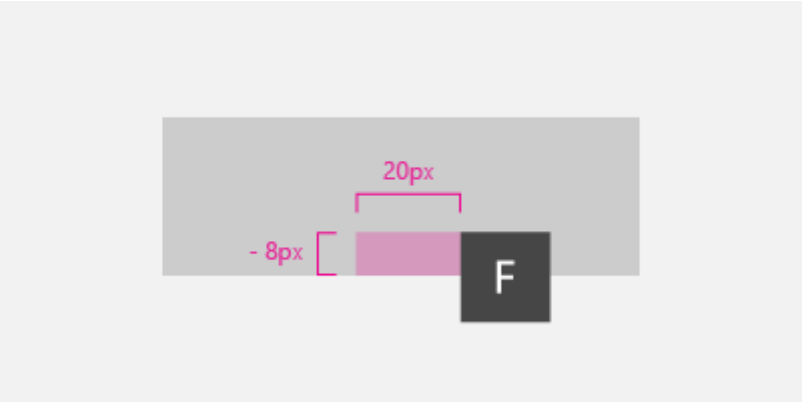
```
  <Button Content="Insert" AccessKey="N" />
</StackPanel>
```

Offsets

Use the KeyTipHorizontalOffset and KeyTipVerticalOffset properties of an element for even more granular control of the keytip location.

> **Note**
>
> Offsets cannot be set when KeyTipPlacementMode is set to Auto.

The KeyTipHorizontalOffset property indicates how far to move the keytip left or right.



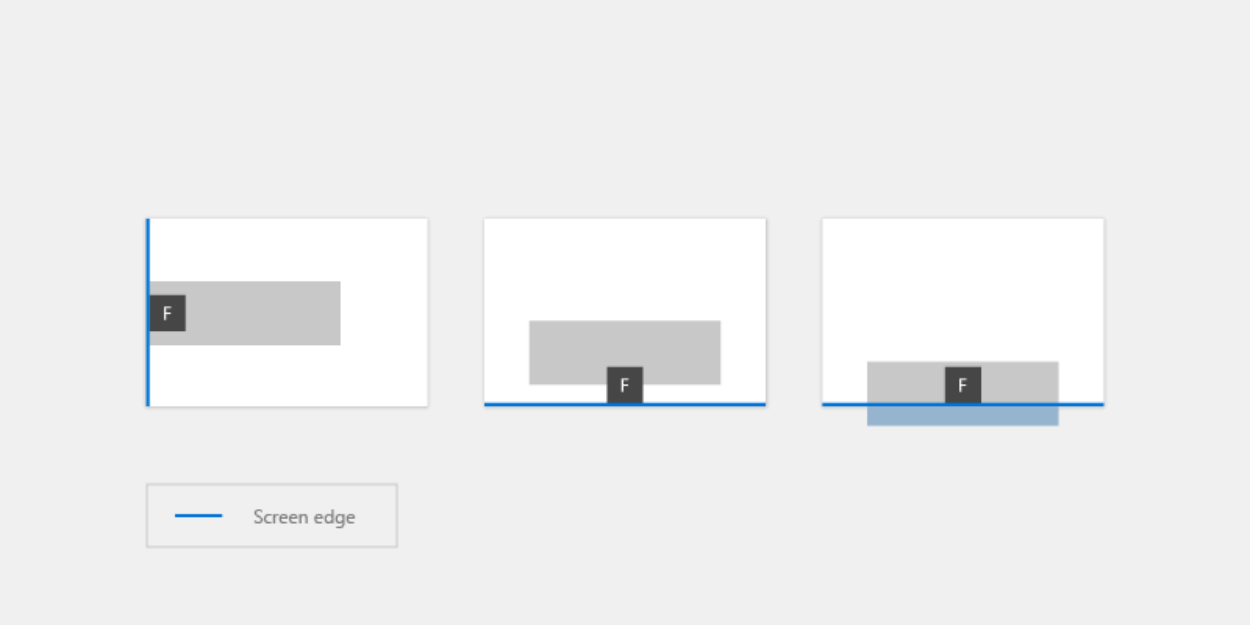
Set vertical and horizontal keytip offsets for a button

XAML

```
<Button
  Content="File"
  AccessKey="F"
  KeyTipPlacementMode="Bottom"
  KeyTipHorizontalOffset="20"
  KeyTipVerticalOffset="-8" />
```

Screen edge alignment {#screen-edge-alignment .ListParagraph}

The location of a keytip is automatically adjusted based on the screen edge to ensure the keytip is fully visible. When this occurs, the distance between the control and keytip alignment point might differ from the values specified for the horizontal and vertical offsets .

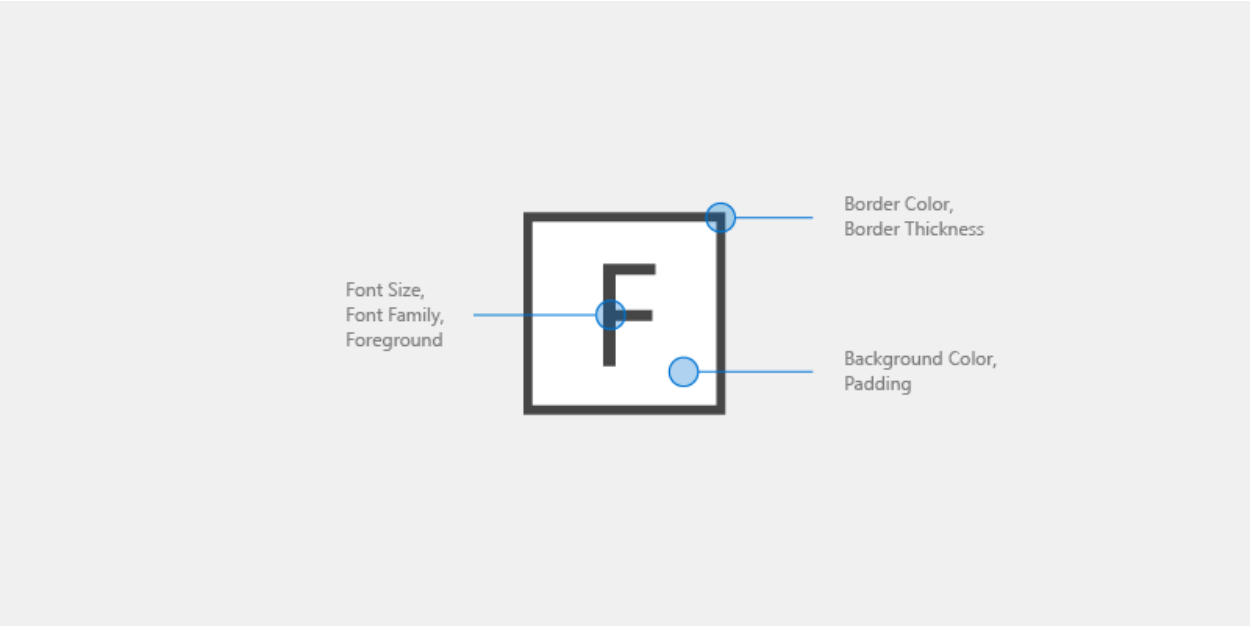


keytips are automatically positioned based on the screen edge

Keytip style

We recommend using the built-in keytip support for platform themes, including high contrast.

If you need to specify your own keytip styles, use application resources such as KeyTipFontSize (font size), KeyTipFontFamily (font family), KeyTipBackground (background), KeyTipForeground (foreground), KeyTipPadding (padding), KeyTipBorderBrush(Border color), and KeyTipBorderThemeThickness (border thickness).



keytip customization options

This example demonstrates how to change these application resources:

XAML

```
<Application.Resources>
 <SolidColorBrush Color="DarkGray" x:Key="MyBackgroundColor" />
 <SolidColorBrush Color="White" x:Key="MyForegroundColor" />
 <SolidColorBrush Color="Black" x:Key="MyBorderColor" />
 <StaticResource x:Key="KeyTipBackground" ResourceKey="MyBackgroundColor" />
 <StaticResource x:Key="KeyTipForeground" ResourceKey="MyForegroundColor" />
 <StaticResource x:Key="KeyTipBorderBrush" ResourceKey="MyBorderColor"/>
 <FontFamily x:Key="KeyTipFontFamily">Consolas</FontFamily>
 <x:Double x:Key="KeyTipContentThemeFontSize">18</x:Double>
 <Thickness x:Key="KeyTipBorderThemeThickness">2</Thickness>
 <Thickness x:Key="KeyTipThemePadding">4,4,4,4</Thickness>
</Application.Resources>
```

Access keys and Narrator

The XAML framework exposes Automation Properties that enable UI Automation clients to discover information about elements in the user interface.

If you specify the AccessKey property on a UIElement or TextElement control, you can use the AutomationProperties.AccessKey property to get this value. Accessibility clients, such as Narrator, read the value of this property each time an element gets focus.

Keyboard accelerators

Article • 05/17/2022

Accelerator keys (or keyboard accelerators) are keyboard shortcuts that improve the usability and accessibility of your Windows applications by providing an intuitive way for users to invoke common actions or commands without navigating the app UI.

> **Note**
>
> A keyboard is indispensable for users with certain disabilities (see Keyboard accessibility), and is also an important tool for users who prefer it as a more efficient way to interact with an app.

See the Access keys topic for details on navigating the UI of a Windows application with keyboard shortcuts.

To create your own custom keyboard shortcuts, see the Keyboard events topic.

Overview

Accelerators are composed of two types of keys: modifiers and non-modifiers. Modifier keys include Shift, Menu, Control, and the Windows key, which are exposed through VirtualKeyModifiers. Non-modifiers include any VirtualKey, such as Delete, F3, Spacebar, Arrow, Esc, and all alphanumeric and punctuation keys.

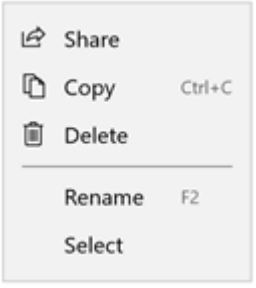
> **Note**
>
> Accelerators typically include the function keys F1 through F12 or some combination of a standard key paired with one or more modifier keys (CTRL, Shift).

For example, if a user presses Ctrl+Shift+M, the framework checks the modifiers (Ctrl and Shift) and fires the accelerator, if it exists.

Many XAML controls have built-in keyboard accelerators. For example, ListView supports Ctrl+A for selecting all the items in the list, and RichEditBox supports Ctrl+Tab for inserting a Tab in the text box. These built-in keyboard accelerators are referred to as **control accelerators** and are executed only if the focus is on the element or one of its children. Accelerators defined by you using the keyboard accelerator APIs discussed here are referred to as **app accelerators**.

Keyboard accelerators are not available for every action but are often associated with commands exposed in menus (and should be specified with the menu item content). Accelerators can also be associated with actions that do not have equivalent menu items. However, because users rely on an application's menus to discover and learn the available command set, you should try to make discovery of accelerators as easy as possible (using labels or established patterns can help with this).

An accelerator auto-repeats (for example, when the user presses Ctrl+Shift and then holds down M, the accelerator is invoked repeatedly until M is released). This behavior cannot be modified.



Keyboard accelerators described in a menu item label

When to use keyboard accelerators

We recommend that you specify keyboard accelerators wherever appropriate in your UI, and support accelerators in all custom controls.

- Keyboard accelerators make your app more accessible for users with motor disabilities, including those users who can press only one key at a time or have difficulty using a mouse.

  A well-designed keyboard UI is an important aspect of software accessibility. It enables users with vision impairments or who have certain motor disabilities to navigate an app and interact with its features. Such users might not be able to operate a mouse and instead rely on various assistive technologies such as

keyboard enhancement tools, on-screen keyboards, screen enlargers, screen readers, and voice input utilities. For these users, comprehensive command coverage is crucial.

- Keyboard accelerators make your app more usable for power users who prefer to interact through the keyboard.

  Experienced users often have a strong preference for using the keyboard because keyboard-based commands can be entered more quickly and don't require them to remove their hands from the keyboard. For these users, efficiency and consistency are crucial; comprehensiveness is important only for the most frequently used commands.

Specify a keyboard accelerator

Use the KeyboardAccelerator APIs to create keyboard accelerators in Windows apps. With these APIs, you don't have to handle multiple KeyDown events to detect the key combination pressed, and you can localize accelerators in the app resources.

We recommend that you set keyboard accelerators for the most common actions in your app and document them using the menu item label or tooltip. In this example, we declare keyboard accelerators only for the Rename and Copy commands.

XAML

```
<CommandBar Margin="0,200" AccessKey="M">
  <AppBarButton
    Icon="Share"
    Label="Share"
    Click="OnShare"
    AccessKey="S" />
  <AppBarButton
    Icon="Copy"
    Label="Copy"
    ToolTipService.ToolTip="Copy (Ctrl+C)"
    Click="OnCopy"
    AccessKey="C">
    <AppBarButton.KeyboardAccelerators>
      <KeyboardAccelerator
        Modifiers="Control"
        Key="C" />
    </AppBarButton.KeyboardAccelerators>
  </AppBarButton>

  <AppBarButton
    Icon="Delete"
    Label="Delete"
    Click="OnDelete"
```

```
      AccessKey="D" />
    <AppBarSeparator/>
    <AppBarButton
      Icon="Rename"
      Label="Rename"
      ToolTipService.ToolTip="Rename (F2)"
      Click="OnRename"
      AccessKey="R">
      <AppBarButton.KeyboardAccelerators>
        <KeyboardAccelerator
          Modifiers="None" Key="F2" />
      </AppBarButton.KeyboardAccelerators>
    </AppBarButton>

    <AppBarButton
      Icon="SelectAll"
      Label="Select"
      Click="OnSelect"
      AccessKey="A" />

    <CommandBar.SecondaryCommands>
      <AppBarButton
        Icon="OpenWith"
        Label="Sources"
        AccessKey="S">
        <AppBarButton.Flyout>
          <MenuFlyout>
            <ToggleMenuFlyoutItem Text="OneDrive" />
            <ToggleMenuFlyoutItem Text="Contacts" />
            <ToggleMenuFlyoutItem Text="Photos"/>
            <ToggleMenuFlyoutItem Text="Videos"/>
          </MenuFlyout>
        </AppBarButton.Flyout>
      </AppBarButton>
      <AppBarToggleButton
        Icon="Save"
        Label="Auto Save"
        IsChecked="True"
        AccessKey="A"/>
    </CommandBar.SecondaryCommands>

  </CommandBar>
```

Keyboard accelerator described in a tooltip

The UIElement object has a KeyboardAccelerator collection, KeyboardAccelerators, where you specify your custom KeyboardAccelerator objects and define the keystrokes

for the keyboard accelerator:

- **Key** - the VirtualKey used for the keyboard accelerator.
- **Modifiers** – the VirtualKeyModifiers used for the keyboard accelerator. If Modifiers is not set, the default value is None.

> ⓘ **Note**
>
> Single key (A, Delete, F2, Spacebar, Esc, Multimedia Key) accelerators and multi-key accelerators (Ctrl+Shift+M) are supported. However, Gamepad virtual keys are not supported.

Scoped accelerators

Some accelerators work only in specific scopes while others work app-wide.

For example, Microsoft Outlook includes the following accelerators:

- Ctrl+B, Ctrl+I and ESC work only on the scope of the send email form
- Ctrl+1 and Ctrl+2 work app-wide

Context menus

Context menu actions affect only specific areas or elements, such as the selected characters in a text editor or a song in a playlist. For this reason, we recommend setting the scope of keyboard accelerators for context menu items to the parent of the context menu.

Use the ScopeOwner property to specify the scope of the keyboard accelerator. This code demonstrates how to implement a context menu on a ListView with scoped keyboard accelerators:

XAML

```
<ListView x:Name="MyList">
  <ListView.ContextFlyout>
    <MenuFlyout>
      <MenuFlyoutItem Text="Share" Icon="Share"/>
      <MenuFlyoutItem Text="Copy" Icon="Copy">
        <MenuFlyoutItem.KeyboardAccelerators>
          <KeyboardAccelerator
            Modifiers="Control"
            Key="C"
```

```
            ScopeOwner="{x:Bind MyList }" />
        </MenuFlyoutItem.KeyboardAccelerators>
      </MenuFlyoutItem>

      <MenuFlyoutItem Text="Delete" Icon="Delete" />
      <MenuFlyoutSeparator />

      <MenuFlyoutItem Text="Rename">
        <MenuFlyoutItem.KeyboardAccelerators>
          <KeyboardAccelerator
            Modifiers="None"
            Key="F2"
            ScopeOwner="{x:Bind MyList}" />
        </MenuFlyoutItem.KeyboardAccelerators>
      </MenuFlyoutItem>

      <MenuFlyoutItem Text="Select" />
    </MenuFlyout>

  </ListView.ContextFlyout>

  <ListViewItem>Track 1</ListViewItem>
  <ListViewItem>Alternative Track 1</ListViewItem>

</ListView>
```

The ScopeOwner attribute of the MenuFlyoutItem.KeyboardAccelerators element marks the accelerator as scoped instead of global (the default is null, or global). For more detail, see the **Resolving accelerators** section later in this topic.

Invoke a keyboard accelerator

The KeyboardAccelerator object uses the UI Automation (UIA) control pattern to take action when an accelerator is invoked.

The UIA [control patterns] expose common control functionality. For example, the Button control implements the Invoke control pattern to support the Click event (typically a control is invoked by clicking, double-clicking, or pressing Enter, a predefined keyboard shortcut, or some other combination of keystrokes). When a keyboard accelerator is used to invoke a control, the XAML framework looks up whether the control implements the Invoke control pattern and, if so, activates it (it is not necessary to listen for the KeyboardAcceleratorInvoked event).

In the following example, Control+S triggers the Click event because the button implements the Invoke pattern.

XAML

```
<Button Content="Save" Click="OnSave">
  <Button.KeyboardAccelerators>
    <KeyboardAccelerator Key="S" Modifiers="Control" />
  </Button.KeyboardAccelerators>
</Button>
```

If an element implements multiple control patterns, only one can be activated through an accelerator. The control patterns are prioritized as follows:

1. Invoke (Button)
2. Toggle (Checkbox)
3. Selection (ListView)
4. Expand/Collapse (ComboBox)

If no match is identified, the accelerator is invalid and a debug message is provided ("No automation patterns for this component found. Implement all desired behavior in the Invoked event. Setting Handled to true in your event handler suppresses this message.")

Custom keyboard accelerator behavior

The Invoked event of the KeyboardAccelerator object is fired when the accelerator is executed. The KeyboardAcceleratorInvokedEventArgs event object includes the following properties:

- **Handled** (Boolean): Setting this to true prevents the event triggering the control pattern and stops accelerator event bubbling. The default is false.
- **Element** (DependencyObject): The object associated with the accelerator.
- **KeyboardAccelerator**: The keyboard accelerator used to raise the Invoked event.

Here we demonstrate how to define a collection of keyboard accelerators for items in a ListView, and how to handle the Invoked event for each accelerator.

XAML

```
<ListView x:Name="MyListView">
  <ListView.KeyboardAccelerators>
    <KeyboardAccelerator Key="A" Modifiers="Control,Shift"
Invoked="SelectAllInvoked" />
    <KeyboardAccelerator Key="F5" Invoked="RefreshInvoked"  />
  </ListView.KeyboardAccelerators>
</ListView>
```

C#

```
void SelectAllInvoked(KeyboardAccelerator sender,
KeyboardAcceleratorInvokedEventArgs args)
{
  MyListView.SelectAll();
  args.Handled = true;
}

void RefreshInvoked(KeyboardAccelerator sender,
KeyboardAcceleratorInvokedEventArgs args)
{
  MyListView.SelectionMode = ListViewSelectionMode.None;
  MyListView.SelectionMode = ListViewSelectionMode.Multiple;
  args.Handled = true;
}
```

Override default keyboard behavior

Some controls, when they have focus, support built-in keyboard accelerators that override any app-defined accelerator. For example, when a TextBox has focus, the Control+C accelerator only copies the currently selected text (app-defined accelerators are ignored and no other functionality is executed).

While we don't recommend overriding default control behaviors due to user familiarity and expectations, you can override a control's built-in keyboard accelerator. The following example shows how to override the Control+C keyboard accelerator for a TextBox through the PreviewKeyDown event handler:

C#

```
 private void TextBlock_PreviewKeyDown(object sender, KeyRoutedEventArgs e)
 {
    var ctrlState =
CoreWindow.GetForCurrentThread().GetKeyState(Windows.System.VirtualKey.Contr
ol);
    var isCtrlDown = ctrlState == CoreVirtualKeyStates.Down || ctrlState
        ==  (CoreVirtualKeyStates.Down | CoreVirtualKeyStates.Locked);
    if (isCtrlDown && e.Key == Windows.System.VirtualKey.C)
    {
        // Your custom keyboard accelerator behavior.

        e.Handled = true;
    }
 }
```

Disable a keyboard accelerator

If a control is disabled, the associated accelerator is also disabled. In the following example, because the IsEnabled property of the ListView is set to false, the associated Control+A accelerator can't be invoked.

XAML

```
<ListView >
  <ListView.KeyboardAccelerators>
    <KeyboardAccelerator Key="A"
      Modifiers="Control"
      Invoked="CustomListViewSelecAllInvoked" />
  </ListView.KeyboardAccelerators>

  <TextBox>
    <TextBox.KeyboardAccelerators>
      <KeyboardAccelerator
        Key="A"
        Modifiers="Control"
        Invoked="CustomTextSelecAllInvoked"
        IsEnabled="False" />
    </TextBox.KeyboardAccelerators>
  </TextBox>

<ListView>
```

Parent and child controls can share the same accelerator. In this case, the parent control can be invoked even if the child has focus and its accelerator is disabled.

Screen readers and keyboard accelerators

Screen readers such as Narrator can announce the keyboard accelerator key combination to users. By default, this is each modifier (in the VirtualModifiers enum order) followed by the key (and separated by "+" signs). You can customize this through the AcceleratorKey AutomationProperties attached property. If more than one accelerator is specified, only the first is announced.

In this example, the AutomationProperty.AcceleratorKey returns the string "Control+Shift+A":

XAML

```
<ListView x:Name="MyListView">
  <ListView.KeyboardAccelerators>

    <KeyboardAccelerator
      Key="A"
      Modifiers="Control,Shift"
      Invoked="CustomSelectAllInvoked" />
```

```
    <KeyboardAccelerator
      Key="F5"
      Modifiers="None"
      Invoked="RefreshInvoked" />

  </ListView.KeyboardAccelerators>

</ListView>
```

> **Note**
>
> Setting AutomationProperties.AcceleratorKey doesn't enable keyboard functionality, it only indicates to the UIA framework which keys are used.

Common Keyboard Accelerators

We recommend that you make keyboard accelerators consistent across Windows applications.

Users have to memorize keyboard accelerators and expect the same (or similar) results, but this might not always be possible due to differences in functionality across apps.

Expand table

Editing	Common Keyboard Accelerator
Begin editing mode	Ctrl + E
Select all items in a focused control or window	Ctrl + A
Search and replace	Ctrl + H
Undo	Ctrl + Z
Redo	Ctrl + Y
Delete selection and copy it to the clipboard	Ctrl + X
Copy selection to the clipboard	Ctrl + C, Ctrl + Insert
Paste the contents of the clipboard	Ctrl + V, Shift + Insert
Paste the contents of the clipboard (with options)	Ctrl + Alt + V
Rename an item	F2

Editing	Common Keyboard Accelerator
Add a new item	Ctrl + N
Add a new secondary item	Ctrl + Shift + N
Delete selected item (with undo)	Del, Ctrl+D
Delete selected item (without undo)	Shift + Del
Bold	Ctrl + B
Underline	Ctrl + U
Italic	Ctrl + I
Navigation	
Find content in a focused control or Window	Ctrl + F
Go to the next search result	F3
Go to the next UI pane	F6
Go to the previous UI pane	Shift + F6
Other Actions	
Add favorites	Ctrl + D
Refresh	F5 or Ctrl + R
Zoom In	Ctrl + +
Zoom out	Ctrl + -
Zoom to default view	Ctrl + 0
Save	Ctrl + S
Close	Ctrl + W
Print	Ctrl + P

Notice that some of the combinations are not valid for localized versions of Windows. For example, in the Spanish version of Windows, Ctrl+N is used for bold instead of Ctrl+B. We recommend providing localized keyboard accelerators if the app is localized.

Usability affordances for keyboard accelerators

Tooltips

As keyboard accelerators are not typically described directly in the UI of your Windows application, you can improve discoverability through tooltips, which display automatically when the user moves focus to, presses and holds, or hovers the mouse pointer over a control. The tooltip can identify whether a control has an associated keyboard accelerator and, if so, what the accelerator key combination is.

Windows 10, Version 1803 (April 2018 Update) and newer

By default, when keyboard accelerators are declared, all controls (except MenuFlyoutItem and ToggleMenuFlyoutItem) present the corresponding key combinations in a tooltip.

> ⓘ **Note**
>
> If a control has more than one accelerator defined, only the first is presented.

Accelerator key combo in tooltip

For Button, AppBarButton, and AppBarToggleButton objects, the keyboard accelerator is appended to the control's default tooltip. For MenuFlyoutItem and ToggleMenuFlyoutItem objects, the keyboard accelerator is displayed with the flyout text.

> ⓘ **Note**
>
> Specifying a tooltip (see Button1 in the following example) overrides this behavior.

XAML

```
<StackPanel x:Name="Container" Grid.Row="0" Background="AliceBlue">
    <Button Content="Button1" Margin="20"
            Click="OnSave"
            KeyboardAcceleratorPlacementMode="Auto"
            ToolTipService.ToolTip="Tooltip">
        <Button.KeyboardAccelerators>
            <KeyboardAccelerator  Key="A" Modifiers="Windows"/>
        </Button.KeyboardAccelerators>
```

```
    </Button>
    <Button Content="Button2"  Margin="20"
            Click="OnSave"
            KeyboardAcceleratorPlacementMode="Auto">
        <Button.KeyboardAccelerators>
            <KeyboardAccelerator  Key="B" Modifiers="Windows"/>
        </Button.KeyboardAccelerators>
    </Button>
    <Button Content="Button3"  Margin="20"
            Click="OnSave"
            KeyboardAcceleratorPlacementMode="Auto">
        <Button.KeyboardAccelerators>
            <KeyboardAccelerator  Key="C" Modifiers="Windows"/>
        </Button.KeyboardAccelerators>
    </Button>
</StackPanel>
```

Accelerator key combo appended to Button's default tooltip

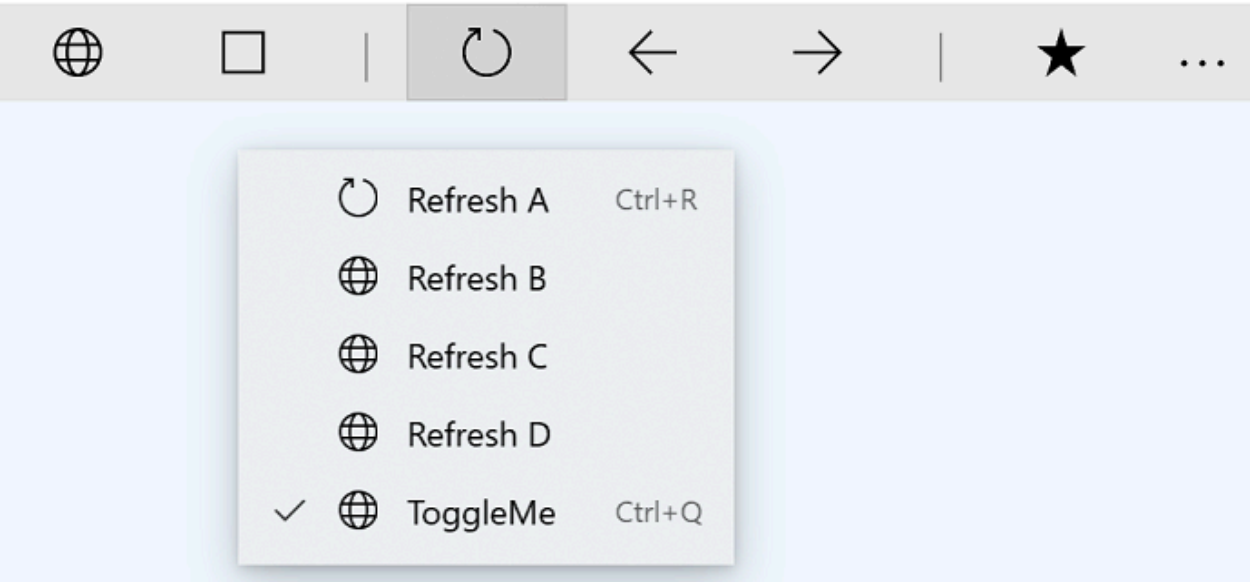
XAML

```
<AppBarButton Icon="Save" Label="Save">
    <AppBarButton.KeyboardAccelerators>
        <KeyboardAccelerator Key="S" Modifiers="Control"/>
    </AppBarButton.KeyboardAccelerators>
</AppBarButton>
```

Accelerator key combo appended to AppBarButton's default tooltip

XAML

```
<AppBarButton AccessKey="R" Icon="Refresh" Label="Refresh"
IsAccessKeyScope="True">
    <AppBarButton.Flyout>
        <MenuFlyout>
            <MenuFlyoutItem AccessKey="A" Icon="Refresh" Text="Refresh A">
                <MenuFlyoutItem.KeyboardAccelerators>
                    <KeyboardAccelerator Key="R" Modifiers="Control"/>
                </MenuFlyoutItem.KeyboardAccelerators>
            </MenuFlyoutItem>
            <MenuFlyoutItem AccessKey="B" Icon="Globe" Text="Refresh B" />
            <MenuFlyoutItem AccessKey="C" Icon="Globe" Text="Refresh C" />
            <MenuFlyoutItem AccessKey="D" Icon="Globe" Text="Refresh D" />
            <ToggleMenuFlyoutItem AccessKey="E" Icon="Globe"
Text="ToggleMe">
                <MenuFlyoutItem.KeyboardAccelerators>
                    <KeyboardAccelerator Key="Q" Modifiers="Control"/>
                </MenuFlyoutItem.KeyboardAccelerators>
            </ToggleMenuFlyoutItem>
        </MenuFlyout>
    </AppBarButton.Flyout>
</AppBarButton>
```



Accelerator key combo appended to MenuFlyoutItem's text

Control the presentation behavior by using the KeyboardAcceleratorPlacementMode property, which accepts two values: Auto or Hidden.

XAML

```
<Button Content="Save" Click="OnSave"
KeyboardAcceleratorPlacementMode="Auto">
    <Button.KeyboardAccelerators>
        <KeyboardAccelerator Key="S" Modifiers="Control" />
```

```
    </Button.KeyboardAccelerators>
</Button>
```

In some cases, you might need to present a tooltip relative to another element (typically a container object).

Here, we show how to use the KeyboardAcceleratorPlacementTarget property to display the keyboard accelerator key combination for a Save button with the Grid container instead of the button.

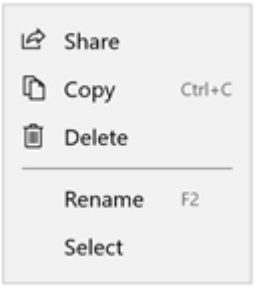
XAML

```
<Grid x:Name="Container" Padding="30">
  <Button Content="Save"
    Click="OnSave"
    KeyboardAcceleratorPlacementMode="Auto"
    KeyboardAcceleratorPlacementTarget="{x:Bind Container}">
    <Button.KeyboardAccelerators>
      <KeyboardAccelerator  Key="S" Modifiers="Control" />
    </Button.KeyboardAccelerators>
  </Button>
</Grid>
```

Labels

In some cases, we recommend using a control's label to identify whether the control has an associated keyboard accelerator and, if so, what the accelerator key combination is.

Some platform controls do this by default, specifically the MenuFlyoutItem and ToggleMenuFlyoutItem objects, while the AppBarButton and the AppBarToggleButton do it when they appear in the overflow menu of the CommandBar.



Keyboard accelerators described in a menu item label

You can override the default accelerator text for the label through the KeyboardAcceleratorTextOverride property of the MenuFlyoutItem, ToggleMenuFlyoutItem, AppBarButton, and AppBarToggleButton controls (use a single space for no text).

> **Note**
>
> The override text is not be presented if the system cannot detect an attached keyboard (you can check this yourself through the KeyboardPresent property).

Advanced Concepts

Here, we review some low-level aspects of keyboard accelerators.

Input event priority

Input events occur in a specific sequence that you can intercept and handle based on the requirements of your app.

The KeyDown/KeyUp bubbling event

In XAML, a keystroke is processed as if there is just one input bubbling pipeline. This input pipeline is used by the KeyDown/KeyUp events and character input. For example, if an element has focus and the user presses a key down, a KeyDown event is raised on the element, followed by the parent of the element, and so on up the tree, until the args.Handled property is true.

The KeyDown event is also used by some controls to implement the built-in control accelerators. When a control has a keyboard accelerator, it handles the KeyDown event, which means that there won't be KeyDown event bubbling. For example, the RichEditBox supports copy with Ctrl+C. When Ctrl is pressed, the KeyDown event is fired and bubbles, but when the user presses C at the same time, the KeyDown event is marked Handled and is not raised (unless the handledEventsToo parameter of UIElement.AddHandler is set to true).

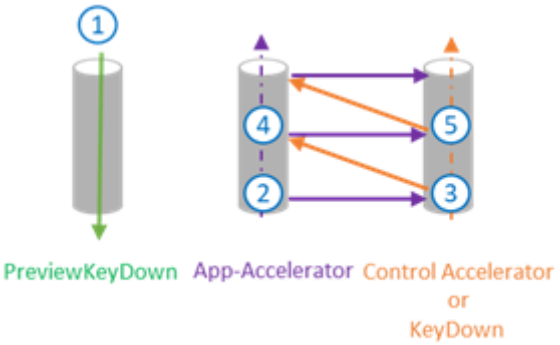
The CharacterReceived event

As the CharacterReceived event is fired after the KeyDown event for text controls such as TextBox, you can cancel character input in the KeyDown event handler.

The PreviewKeyDown and PreviewKeyUp events

The preview input events are fired before any other events. If you don't handle these events, the accelerator for the element that has the focus is fired, followed by the

KeyDown event. Both events bubble until handled.



Key event sequence

Order of events:

Preview KeyDown events
...
App accelerator
OnKeyDown method
KeyDown event
App accelerators on the parent
OnKeyDown method on the parent
KeyDown event on the parent
(Bubbles to the root)
...
CharacterReceived event
PreviewKeyUp events
KeyUpEvents

When the accelerator event is handled, the KeyDown event is also marked as handled. The KeyUp event remains unhandled.

Resolving accelerators

A keyboard accelerator event bubbles from the element that has focus up to the root. If the event isn't handled, the XAML framework looks for other unscoped app accelerators outside of the bubbling path.

When two keyboard accelerators are defined with the same key combination, the first keyboard accelerator found on the visual tree is invoked.

Scoped keyboard accelerators are invoked only when focus is inside a specific scope. For example, in a Grid that contains dozens of controls, a keyboard accelerator can be invoked for a control only when focus is within the Grid (the scope owner).

Scoping accelerators programmatically

The UIElement.TryInvokeKeyboardAccelerator method invokes any matching accelerators in the subtree of the element.

The UIElement.OnProcessKeyboardAccelerators method is executed before the keyboard accelerator. This method passes a ProcessKeyboardAcceleratorArgs object that contains the key, the modifier, and a Boolean indicating whether the keyboard accelerator is handled. If marked as handled, the keyboard accelerator bubbles (so the outside keyboard accelerator is never invoked).

> **Note**
>
> OnProcessKeyboardAccelerators always fires, whether handled or not (similar to the OnKeyDown event). You must check whether the event was marked as handled.

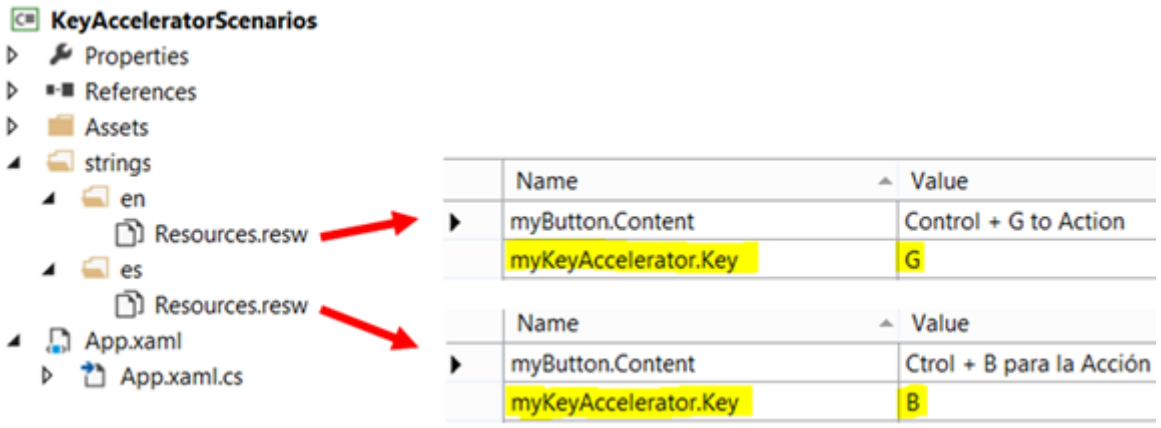
In this example, we use OnProcessKeyboardAccelerators and TryInvokeKeyboardAccelerator to scope keyboard accelerators to the Page object:

C#

```
protected override void OnProcessKeyboardAccelerators(
  ProcessKeyboardAcceleratorArgs args)
{
  if(args.Handled != true)
  {
    this.TryInvokeKeyboardAccelerator(args);
    args.Handled = true;
  }
}
```

Localize the accelerators

We recommend localizing all keyboard accelerators. You can do this with the standard resources (.resw) file and the x:Uid attribute in your XAML declarations. In this example, the Windows Runtime automatically loads the resources.



Keyboard accelerator localization with the resources file

XAML

```
<Button x:Uid="myButton" Click="OnSave">
  <Button.KeyboardAccelerators>
    <KeyboardAccelerator x:Uid="myKeyAccelerator" Modifiers="Control"/>
  </Button.KeyboardAccelerators>
</Button>
```

> **Note**
>
> Keyboard accelerators are implemented as virtual-keys. Localized accelerators must be chosen from the predefined collection of Virtual-Key codes (otherwise, a XAML parser error will occur).

Setup an accelerator programmatically

Here is an example of programmatically defining an accelerator:

C#

```
void AddAccelerator(
  VirtualKeyModifiers keyModifiers,
  VirtualKey key,
  TypedEventHandler<KeyboardAccelerator,
KeyboardAcceleratorInvokedEventArgs> handler )
  {
    var accelerator =
      new KeyboardAccelerator()
      {
        Modifiers = keyModifiers, Key = key
      };
    accelerator.Invoked += handler;
```

```
    this.KeyboardAccelerators.Add(accelerator);
  }
```

> **Note**
>
> KeyboardAccelerator is not shareable, the same KeyboardAccelerator can't be added to multiple elements.

Override keyboard accelerator behavior

You can handle the KeyboardAccelerator.Invoked event to override the default KeyboardAccelerator behavior.

This example shows how to override the "Select all" command (Ctrl+A keyboard accelerator) in a custom ListView control. We also set the Handled property to true to stop the event bubbling further.

C#

```
public class MyListView : ListView
{
  …
  protected override void
OnKeyboardAcceleratorInvoked(KeyboardAcceleratorInvokedEventArgs args)
  {
    if(args.Accelerator.Key == VirtualKey.A
      && args.Accelerator.Modifiers == KeyboardModifiers.Control)
    {
      CustomSelectAll(TypeOfSelection.OnlyNumbers);
      args.Handled = true;
    }
  }
  …
}
```

Keyboard events

Article • 10/04/2021

Keyboard events and focus

The following keyboard events can occur for both hardware and touch keyboards.

Expand table

Event	Description
KeyDown	Occurs when a key is pressed.
KeyUp	Occurs when a key is released.

> **Important**
>
> Some XAML controls handle input events internally. In these cases, it might appear that an input event doesn't occur because your event listener doesn't invoke the associated handler. Typically, this subset of keys is processed by the class handler to provide built in support of basic keyboard accessibility. For example, the Button class overrides the OnKeyDown events for both the Space key and the Enter key (as well as OnPointerPressed) and routes them to the Click event of the control. When a key press is handled by the control class, the KeyDown and KeyUp events are not raised.
> This provides a built-in keyboard equivalent for invoking the button, similar to tapping it with a finger or clicking it with a mouse. Keys other than Space or Enter still fire KeyDown and KeyUp events. For more info about how class-based handling of events works (specifically, the "Input event handlers in controls" section), see Events and routed events overview.

Controls in your UI generate keyboard events only when they have input focus. An individual control gains focus when the user clicks or taps directly on that control in the layout, or uses the Tab key to step into a tab sequence within the content area.

You can also call a control's Focus method to force focus. This is necessary when you implement shortcut keys, because keyboard focus is not set by default when your UI loads. For more info, see the **Shortcut keys example** later in this topic.

For a control to receive input focus, it must be enabled, visible, and have **IsTabStop** and **HitTestVisible** property values of **true**. This is the default state for most controls. When a control has input focus, it can raise and respond to keyboard input events as described later in this topic. You can also respond to a control that is receiving or losing focus by handling the **GotFocus** and **LostFocus** events.

By default, the tab sequence of controls is the order in which they appear in the Extensible Application Markup Language (XAML). However, you can modify this order by using the **TabIndex** property. For more info, see Implementing keyboard accessibility.

Keyboard event handlers

An input event handler implements a delegate that provides the following information:

- The sender of the event. The sender reports the object where the event handler is attached.
- Event data. For keyboard events, that data will be an instance of **KeyRoutedEventArgs**. The delegate for handlers is **KeyEventHandler**. The most relevant properties of **KeyRoutedEventArgs** for most handler scenarios are **Key** and possibly **KeyStatus**.
- **OriginalSource**. Because the keyboard events are routed events, the event data provides **OriginalSource**. If you deliberately allow events to bubble up through an object tree, **OriginalSource** is sometimes the object of concern rather than sender. However, that depends on your design. For more information about how you might use **OriginalSource** rather than sender, see the "Keyboard Routed Events" section of this topic, or Events and routed events overview.

Attaching a keyboard event handler

You can attach keyboard event-handler functions for any object that includes the event as a member. This includes any **UIElement** derived class. The following XAML example shows how to attach handlers for the **KeyUp** event for a **Grid**.

XAML

```
<Grid KeyUp="Grid_KeyUp">
  ...
</Grid>
```

You can also attach an event handler in code. For more info, see Events and routed events overview.

Defining a keyboard event handler

The following example shows the incomplete event handler definition for the KeyUp event handler that was attached in the preceding example.

C#

```
void Grid_KeyUp(object sender, KeyRoutedEventArgs e)
{
    //handling code here
}
```

VB

```
Private Sub Grid_KeyUp(ByVal sender As Object, ByVal e As
KeyRoutedEventArgs)
    ' handling code here
End Sub
```

c++

```
void MyProject::MainPage::Grid_KeyUp(
  Platform::Object^ sender,
  Windows::UI::Xaml::Input::KeyRoutedEventArgs^ e)
  {
      //handling code here
  }
```

Using KeyRoutedEventArgs

All keyboard events use KeyRoutedEventArgs for event data, and **KeyRoutedEventArgs** contains the following properties:

- Key
- KeyStatus
- Handled
- OriginalSource (inherited from RoutedEventArgs)

Virtual keys

The KeyDown event is raised if a key is pressed. Likewise, KeyUp is raised if a key is released. Usually, you listen to the events to process a specific key value. To determine which key is pressed or released, check the Key value in the event data. **Key** returns a VirtualKey value. The **VirtualKey** enumeration includes all the supported keys.

Modifier keys

Modifier keys are keys such as Ctrl or Shift that users typically press in combination with other keys. Your app can use these combinations as custom keyboard shortcuts to invoke app commands.

> **Note**
>
> For built-in keyboard shortcuts, see Access keys and Keyboard accelerators.

You can detect shortcut key combinations in the **KeyDown** and **KeyUp** event handlers. When a keyboard event occurs for a non-modifier key, you can then check whether a modifier key is in the pressed state.

Alternatively, the **GetKeyState()** function of the **CoreWindow** (obtained through **CoreWindow.GetForCurrentThread()**) can also be used to check modifier state when a non-modifier key is pressed.

The following examples implement this second method while also including stub code for the first implementation.

> **Note**
>
> The Alt key is represented by the **VirtualKey.Menu** value.

Shortcut keys example

The following example demonstrates how to implement a set of custom shortcut keys. In this example, users can control media playback using Play, Pause, and Stop buttons or Ctrl+P, Ctrl+A, and Ctrl+S keyboard shortcuts. The button XAML shows the shortcuts by using tooltips and **AutomationProperties** properties in the button labels. This self-documentation is important to increase the usability and accessibility of your app. For more info, see Keyboard accessibility.

Note also that the page sets input focus to itself when it is loaded. Without this step, no control has initial input focus, and the app does not raise input events until the user sets the input focus manually (for example, by tabbing to or clicking a control).

XAML

```
<Grid KeyDown="Grid_KeyDown">
```

```
  <Grid.RowDefinitions>
    <RowDefinition Height="Auto" />
    <RowDefinition Height="Auto" />
  </Grid.RowDefinitions>

  <MediaElement x:Name="DemoMovie" Source="xbox.wmv"
    Width="500" Height="500" Margin="20" HorizontalAlignment="Center" />

  <StackPanel Grid.Row="1" Margin="10"
    Orientation="Horizontal" HorizontalAlignment="Center">

    <Button x:Name="PlayButton" Click="MediaButton_Click"
      ToolTipService.ToolTip="Shortcut key: Ctrl+P"
      AutomationProperties.AcceleratorKey="Control P">
      <TextBlock>Play</TextBlock>
    </Button>

    <Button x:Name="PauseButton" Click="MediaButton_Click"
      ToolTipService.ToolTip="Shortcut key: Ctrl+A"
      AutomationProperties.AcceleratorKey="Control A">
      <TextBlock>Pause</TextBlock>
    </Button>

    <Button x:Name="StopButton" Click="MediaButton_Click"
      ToolTipService.ToolTip="Shortcut key: Ctrl+S"
      AutomationProperties.AcceleratorKey="Control S">
      <TextBlock>Stop</TextBlock>
    </Button>

  </StackPanel>

</Grid>
```

c++

```
//showing implementations but not header definitions
void MainPage::OnNavigatedTo(NavigationEventArgs^ e)
{
    (void) e;    // Unused parameter
    this->Loaded+=ref new
RoutedEventHandler(this,&amp;MainPage::ProgrammaticFocus);
}
void MainPage::ProgrammaticFocus(Object^ sender, RoutedEventArgs^ e)
{
    this->Focus(Windows::UI::Xaml::FocusState::Programmatic);
}

void KeyboardSupport::MainPage::MediaButton_Click(Platform::Object^ sender,
Windows::UI::Xaml::RoutedEventArgs^ e)
{
    FrameworkElement^ fe = safe_cast<FrameworkElement^>(sender);
    if (fe->Name == "PlayButton") {DemoMovie->Play();}
    if (fe->Name == "PauseButton") {DemoMovie->Pause();}
```

```
    if (fe->Name == "StopButton") {DemoMovie->Stop();}
}

bool KeyboardSupport::MainPage::IsCtrlKeyPressed()
{
    auto ctrlState = CoreWindow::GetForCurrentThread()-
>GetKeyState(VirtualKey::Control);
    return (ctrlState & CoreVirtualKeyStates::Down) ==
CoreVirtualKeyStates::Down;
}

{
    if (e->Key == VirtualKey::Control) isCtrlKeyPressed = true;
}

void KeyboardSupport::MainPage::Grid_KeyUp(Platform::Object^ sender,
Windows::UI::Xaml::Input::KeyRoutedEventArgs^ e)
{
    if (IsCtrlKeyPressed())
    {
        if (e->Key==VirtualKey::P) { DemoMovie->Play(); }
        if (e->Key==VirtualKey::A) { DemoMovie->Pause(); }
        if (e->Key==VirtualKey::S) { DemoMovie->Stop(); }
    }
}
```

C#

```
protected override void OnNavigatedTo(NavigationEventArgs e)
{
    // Set the input focus to ensure that keyboard events are raised.
    this.Loaded += delegate { this.Focus(FocusState.Programmatic); };
}

private void MediaButton_Click(object sender, RoutedEventArgs e)
{
    switch ((sender as Button).Name)
    {
        case "PlayButton": DemoMovie.Play(); break;
        case "PauseButton": DemoMovie.Pause(); break;
        case "StopButton": DemoMovie.Stop(); break;
    }
}

private static bool IsCtrlKeyPressed()
{
    var ctrlState =
CoreWindow.GetForCurrentThread().GetKeyState(VirtualKey.Control);
    return (ctrlState & CoreVirtualKeyStates.Down) ==
```

```
CoreVirtualKeyStates.Down;
}

private void Grid_KeyDown(object sender, KeyRoutedEventArgs e)
{
    if (IsCtrlKeyPressed())
    {
        switch (e.Key)
        {
            case VirtualKey.P: DemoMovie.Play(); break;
            case VirtualKey.A: DemoMovie.Pause(); break;
            case VirtualKey.S: DemoMovie.Stop(); break;
        }
    }
}
```

VisualBasic

```
Private isCtrlKeyPressed As Boolean
Protected Overrides Sub OnNavigatedTo(e As Navigation.NavigationEventArgs)

End Sub

Private Function IsCtrlKeyPressed As Boolean
    Dim ctrlState As CoreVirtualKeyStates =
CoreWindow.GetForCurrentThread().GetKeyState(VirtualKey.Control);
    Return (ctrlState & CoreVirtualKeyStates.Down) ==
CoreVirtualKeyStates.Down;
End Function

Private Sub Grid_KeyDown(sender As Object, e As KeyRoutedEventArgs)
    If IsCtrlKeyPressed() Then

            Case Windows.System.VirtualKey.A
                DemoMovie.Pause()
            Case Windows.System.VirtualKey.S
                DemoMovie.Stop()
        End Select
    End If
End Sub

Private Sub MediaButton_Click(sender As Object, e As RoutedEventArgs)
    Dim fe As FrameworkElement = CType(sender, FrameworkElement)
    Select Case fe.Name
        Case "PlayButton"
            DemoMovie.Play()
        Case "PauseButton"
            DemoMovie.Pause()
        Case "StopButton"
            DemoMovie.Stop()
```

```
    End Select
End Sub
```

> **Note**
>
> Setting AutomationProperties.AcceleratorKey or AutomationProperties.AccessKey in XAML provides string information, which documents the shortcut key for invoking that particular action. The information is captured by Microsoft UI Automation clients such as Narrator, and is typically provided directly to the user.
>
> Setting **AutomationProperties.AcceleratorKey** or **AutomationProperties.AccessKey** does not have any action on its own. You will still need to attach handlers for KeyDown or KeyUp events in order to actually implement the keyboard shortcut behavior in your app. Also, the underline text decoration for an access key is not provided automatically. You must explicitly underline the text for the specific key in your mnemonic as inline Underline formatting if you wish to show underlined text in the UI.

Keyboard routed events

Certain events are routed events, including KeyDown and KeyUp. Routed events use the bubbling routing strategy. The bubbling routing strategy means that an event originates from a child object and is then routed up to successive parent objects in the object tree. This presents another opportunity to handle the same event and interact with the same event data.

Consider the following XAML example, which handles KeyUp events for a Canvas and two Button objects. In this case, if you release a key while focus is held by either **Button** object, it raises the **KeyUp** event. The event is then bubbled up to the parent **Canvas**.

XAML

```
<StackPanel KeyUp="StackPanel_KeyUp">
  <Button Name="ButtonA" Content="Button A"/>
  <Button Name="ButtonB" Content="Button B"/>
  <TextBlock Name="statusTextBlock"/>
</StackPanel>
```

The following example shows how to implement the KeyUp event handler for the corresponding XAML content in the preceding example.

C#

```
void StackPanel_KeyUp(object sender, KeyRoutedEventArgs e)
{
    statusTextBlock.Text = String.Format(
        "The key {0} was pressed while focus was on {1}",
        e.Key.ToString(), (e.OriginalSource as FrameworkElement).Name);
}
```

Notice the use of the OriginalSource property in the preceding handler. Here, **OriginalSource** reports the object that raised the event. The object could not be the StackPanel because the **StackPanel** is not a control and cannot have focus. Only one of the two buttons within the **StackPanel** could possibly have raised the event, but which one? You use **OriginalSource** to distinguish the actual event source object, if you are handling the event on a parent object.

The Handled property in event data

Depending on your event handling strategy, you might want only one event handler to react to a bubbling event. For instance, if you have a specific KeyUp handler attached to one of the Button controls, it would have the first opportunity to handle that event. In this case, you might not want the parent panel to also handle the event. For this scenario, you can use the Handled property in the event data.

The purpose of the Handled property in a routed event data class is to report that another handler you registered earlier on the event route has already acted. This influences the behavior of the routed event system. When you set **Handled** to **true** in an event handler, that event stops routing and is not sent to successive parent elements.

AddHandler and already-handled keyboard events

You can use a special technique for attaching handlers that can act on events that you already marked as handled. This technique uses the AddHandler method to register a handler, rather than using XAML attributes or language-specific syntax for adding handlers, such as += in C#.

A general limitation of this technique is that the **AddHandler** API takes a parameter of type RoutedEvent identifying the routed event in question. Not all routed events provide a **RoutedEvent** identifier, and this consideration thus affects which routed events can still be handled in the Handled case. The KeyDown and KeyUp events have

routed event identifiers (KeyDownEvent and KeyUpEvent) on UIElement. However, other events such as TextBox.TextChanged do not have routed event identifiers and thus cannot be used with the **AddHandler** technique.

Overriding keyboard events and behavior

You can override key events for specific controls (such as GridView) to provide consistent focus navigation for various input devices, including keyboard and gamepad.

In the following example, we subclass the control and override the KeyDown behavior to move focus to the GridView content when any arrow key is pressed.

C#

```
public class CustomGridView : GridView
{
  protected override void OnKeyDown(KeyRoutedEventArgs e)
  {
    // Override arrow key behaviors.
    if (e.Key != Windows.System.VirtualKey.Left && e.Key !=
      Windows.System.VirtualKey.Right && e.Key !=
        Windows.System.VirtualKey.Down && e.Key !=
          Windows.System.VirtualKey.Up)
            base.OnKeyDown(e);
    else
      FocusManager.TryMoveFocus(FocusNavigationDirection.Down);
  }
}
```

> ⓘ Note
>
> If using a GridView for layout only, consider using other controls such as ItemsControl with ItemsWrapGrid.

Commanding

A small number of UI elements provide built-in support for commanding. Commanding uses input-related routed events in its underlying implementation. It enables processing of related UI input, such as a certain pointer action or a specific accelerator key, by invoking a single command handler.

If commanding is available for a UI element, consider using its commanding APIs instead of any discrete input events. For more info, see ButtonBase.Command.

You can also implement **ICommand** to encapsulate command functionality that you invoke from ordinary event handlers. This enables you to use commanding even when there is no **Command** property available.

Text input and controls

Certain controls react to keyboard events with their own handling. For instance, **TextBox** is a control that is designed to capture and then visually represent text that was entered by using the keyboard. It uses **KeyUp** and **KeyDown** in its own logic to capture keystrokes, then also raises its own **TextChanged** event if the text actually changed.

You can still generally add handlers for **KeyUp** and **KeyDown** to a **TextBox**, or any related control that is intended to process text input. However, as part of its intended design, a control might not respond to all key values that are directed to it through key events. Behavior is specific to each control.

As an example, **ButtonBase** (the base class for **Button**) processes **KeyUp** so that it can check for the Spacebar or Enter key. **ButtonBase** considers **KeyUp** equivalent to a mouse left button down for purposes of raising a **Click** event. This processing of the event is accomplished when **ButtonBase** overrides the virtual method **OnKeyUp**. In its implementation, it sets **Handled** to **true**. The result is that any parent of a button that is listening for a key event, in the case of a Spacebar, would not receive the already-handled event for its own handlers.

Another example is **TextBox**. Some keys, such as the arrow keys, are not considered text by **TextBox** and are instead considered specific to the control UI behavior. The **TextBox** marks these event cases as handled.

Custom controls can implement their own similar override behavior for key events by overriding **OnKeyDown** / **OnKeyUp**. If your custom control processes specific accelerator keys, or has control or focus behavior that is similar to the scenario described for **TextBox**, you should place this logic in your own **OnKeyDown** / **OnKeyUp** overrides.

The touch keyboard

Text input controls provide automatic support for the touch keyboard. When the user sets the input focus to a text control by using touch input, the touch keyboard appears automatically. When the input focus is not on a text control, the touch keyboard is hidden.

When the touch keyboard appears, it automatically repositions your UI to ensure that the focused element remains visible. This can cause other important areas of your UI to move off screen. However, you can disable the default behavior and make your own UI adjustments when the touch keyboard appears. For more info, see the Touch keyboard sample.

If you create a custom control that requires text input, but does not derive from a standard text input control, you can add touch keyboard support by implementing the correct UI Automation control patterns. For more info, see the Touch keyboard sample.

Key presses on the touch keyboard raise **KeyDown** and **KeyUp** events just like key presses on hardware keyboards. However, the touch keyboard will not raise input events for Ctrl+A, Ctrl+Z, Ctrl+X, Ctrl+C, and Ctrl+V, which are reserved for text manipulation in the input control.

You can make it much faster and easier for users to enter data in your app by setting the input scope of the text control to match the kind of data you expect the user to enter. The input scope provides a hint at the type of text input expected by the control so the system can provide a specialized touch keyboard layout for the input type. For example, if a text box is used only to enter a 4-digit PIN, set the **InputScope** property to **Number**. This tells the system to show the numeric keypad layout, which makes it easier for the user to enter the PIN. For more detail, see Use input scope to change the touch keyboard.

Focus navigation for keyboard, gamepad, remote control, and accessibility tools

Article • 06/24/2021

Use focus navigation to provide comprehensive and consistent interaction experiences in your Windows apps and custom controls for keyboard power users, those with disabilities and other accessibility requirements, as well as the 10-foot experience of television screens and the Xbox One.

Overview

Focus navigation refers to the underlying mechanism that enables users to navigate and interact with the UI of a Windows application using a keyboard, gamepad, or remote control.

> **Note**
>
> Input devices are typically classified as pointing devices, such as touch, touchpad, pen, and mouse, and non-pointing devices, such as keyboard, gamepad, and remote control.

This topic describes how to optimize a Windows application and build custom interaction experiences for users that rely on non-pointing input types.

Even though we focus on keyboard input for custom controls in Windows apps on PCs, a well-designed keyboard experience is also important for software keyboards such as the touch keyboard and the On-Screen Keyboard (OSK), supporting accessibility tools such as Windows Narrator, and supporting the 10-foot experience.

See Handle pointer input for guidance on building custom experiences in Windows applications for pointing devices.

For more general information on building apps and experiences for keyboard, see Keyboard Interaction.

General guidance

Only those UI elements that require user interaction should support focus navigation, elements that don't require an action, such as static images, do not need keyboard focus. Screen readers and similar accessibility tools still announce these static elements, even when they are not included in focus navigation.

It is important to remember that unlike navigating with a pointer device such as a mouse or touch, focus navigation is linear. When implementing focus navigation, consider how a user will interact with your application and what the logical navigation should be. In most cases, we recommend custom focus navigation behavior follows the preferred reading pattern of the user's culture.

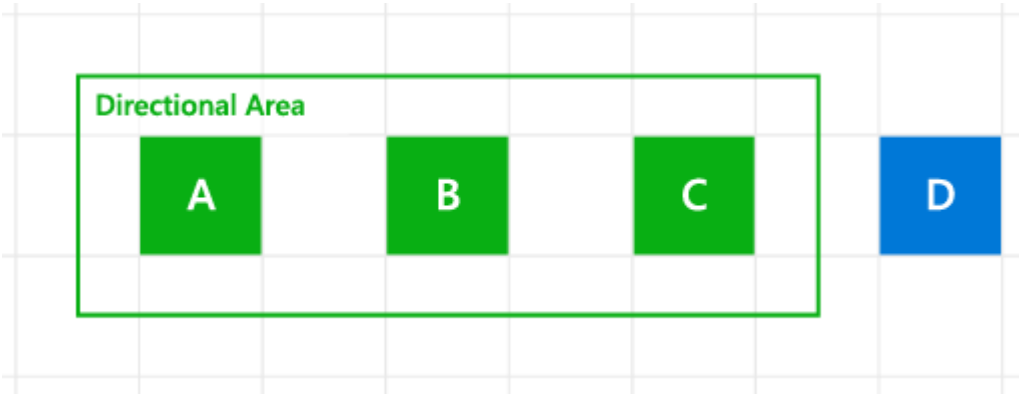
Some other focus navigation considerations include:

- Are controls grouped logically?
- Are there groups of controls with greater importance?
  - If yes, do those groups contain sub-groups?
- Does the layout require custom directional navigation (arrow keys) and tab order?

The Engineering Software for Accessibility eBook has an excellent chapter on *Designing the Logical Hierarchy*.

2D directional navigation for keyboard

The 2D inner navigation region of a control, or control group, is referred to as its "directional area". When focus shifts to this object, the keyboard arrow keys (left, right, up, and down) can be used to navigate between child elements within the directional area.



2D Inner navigation region, or directional area, of a control group

You can use the XYFocusKeyboardNavigation property (which has possible values of Auto, Enabled, or Disabled) to manage 2D inner navigation with the keyboard arrow keys.

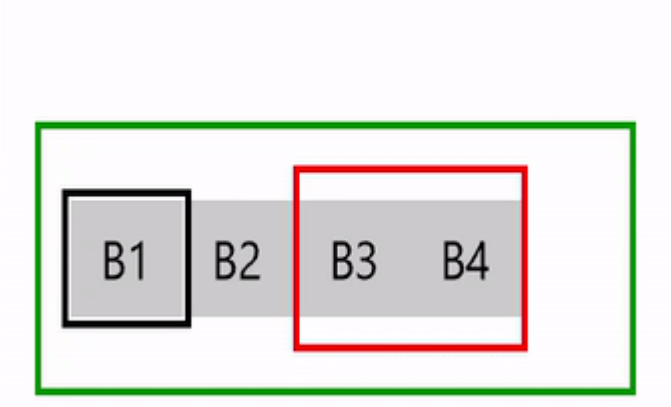
> ⓘ **Note**
>
> Tab order is not affected by this property. To avoid a confusing navigation experience, we recommend that child elements of a directional area *not* be explicitly specified in the tab navigation order of your application. See the **UIElement.TabFocusNavigation** and **TabIndex** properties for more detail on tabbing behavior for an element.

Auto (default behavior)

When set to Auto, directional navigation behavior is determined by the element's ancestry, or inheritance hierarchy. If all ancestors are in default mode (set to **Auto**), directional navigation with the keyboard is *not* supported.

Disabled

Set **XYFocusKeyboardNavigation** to **Disabled** to block directional navigation to the control and its child elements.



XYFocusKeyboardNavigation disabled behavior

In this example, the primary StackPanel (ContainerPrimary) has **XYFocusKeyboardNavigation** set to **Enabled**. All child elements inherit this setting, and can be navigated to with the arrow keys. However, the B3 and B4 elements are in a secondary StackPanel (ContainerSecondary) with **XYFocusKeyboardNavigation** set to **Disabled**, which overrides the primary container and disables arrow key navigation to itself and between its child elements.

XAML

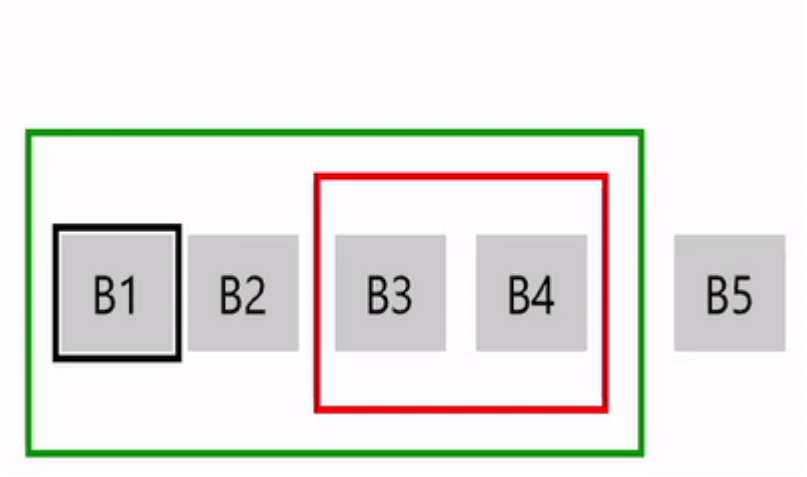
```
<Grid
    Background="{ThemeResource ApplicationPageBackgroundThemeBrush}"
    TabFocusNavigation="Cycle">
    <Grid.RowDefinitions>
        <RowDefinition Height="40"/>
        <RowDefinition Height="75"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <TextBlock Name="KeyPressed"
               Grid.Row="0"
               FontWeight="ExtraBold"
               HorizontalTextAlignment="Center"
               TextWrapping="Wrap"
               Padding="10" />
    <StackPanel Name="ContainerPrimary"
               XYFocusKeyboardNavigation="Enabled"
               KeyDown="ContainerPrimary_KeyDown"
               Orientation="Horizontal"
               BorderBrush="Green"
               BorderThickness="2"
               Grid.Row="1"
               Padding="10"
               MaxWidth="200">
        <Button Name="B1"
               Content="B1"
               GettingFocus="Btn_GettingFocus" />
        <Button Name="B2"
               Content="B2"
               GettingFocus="Btn_GettingFocus" />
        <StackPanel Name="ContainerSecondary"
```

```
                    XYFocusKeyboardNavigation="Disabled"
                    Orientation="Horizontal"
                    BorderBrush="Red"
                    BorderThickness="2">
            <Button Name="B3"
                    Content="B3"
                    GettingFocus="Btn_GettingFocus" />
            <Button Name="B4"
                    Content="B4"
                    GettingFocus="Btn_GettingFocus" />
        </StackPanel>
    </StackPanel>
</Grid>
```

Enabled

Set **XYFocusKeyboardNavigation** to **Enabled** to support 2D directional navigation to a control and each of its UIElement child objects.

When set, navigation with the arrow keys is restricted to elements within the directional area. Tab navigation is not affected, as all controls remain accessible through their tab order hierarchy.



XYFocusKeyboardNavigation enabled behavior

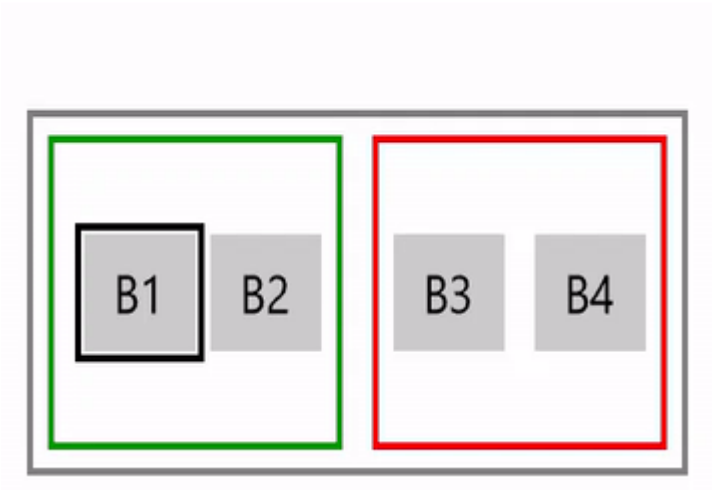
In this example, the primary StackPanel (ContainerPrimary) has **XYFocusKeyboardNavigation** set to **Enabled**. All child elements inherit this setting, and can be navigated to with the arrow keys. The B3 and B4 elements are in a secondary StackPanel (ContainerSecondary) where **XYFocusKeyboardNavigation** is not set, which then inherits the primary container setting. The B5 element is not within a declared directional area, and does not support arrow key navigation but does support standard tab navigation behavior.

XAML

```
<Grid
    Background="{ThemeResource ApplicationPageBackgroundThemeBrush}"
    TabFocusNavigation="Cycle">
    <Grid.RowDefinitions>
        <RowDefinition Height="40"/>
        <RowDefinition Height="100"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <TextBlock Name="KeyPressed"
               Grid.Row="0"
               FontWeight="ExtraBold"
               HorizontalTextAlignment="Center"
               TextWrapping="Wrap"
               Padding="10" />
    <StackPanel Grid.Row="1"
                Orientation="Horizontal"
                HorizontalAlignment="Center">
        <StackPanel Name="ContainerPrimary"
                    XYFocusKeyboardNavigation="Enabled"
                    KeyDown="ContainerPrimary_KeyDown"
                    Orientation="Horizontal"
                    BorderBrush="Green"
                    BorderThickness="2"
                    Padding="5" Margin="5">
            <Button Name="B1"
                    Content="B1"
                    GettingFocus="Btn_GettingFocus" Margin="5" />
            <Button Name="B2"
                    Content="B2"
                    GettingFocus="Btn_GettingFocus" />
            <StackPanel Name="ContainerSecondary"
                        Orientation="Horizontal"
                        BorderBrush="Red"
                        BorderThickness="2"
                        Margin="5">
                <Button Name="B3"
                        Content="B3"
                        GettingFocus="Btn_GettingFocus"
                        Margin="5" />
                <Button Name="B4"
                        Content="B4"
                        GettingFocus="Btn_GettingFocus"
                        Margin="5" />
            </StackPanel>
        </StackPanel>
        <Button Name="B5"
                Content="B5"
                GettingFocus="Btn_GettingFocus"
                Margin="5" />
    </StackPanel>
</Grid>
```

You can have multiple levels of nested directional areas. If all parent elements have XYFocusKeyboardNavigation set to Enabled, inner navigation region boundaries are ignored.

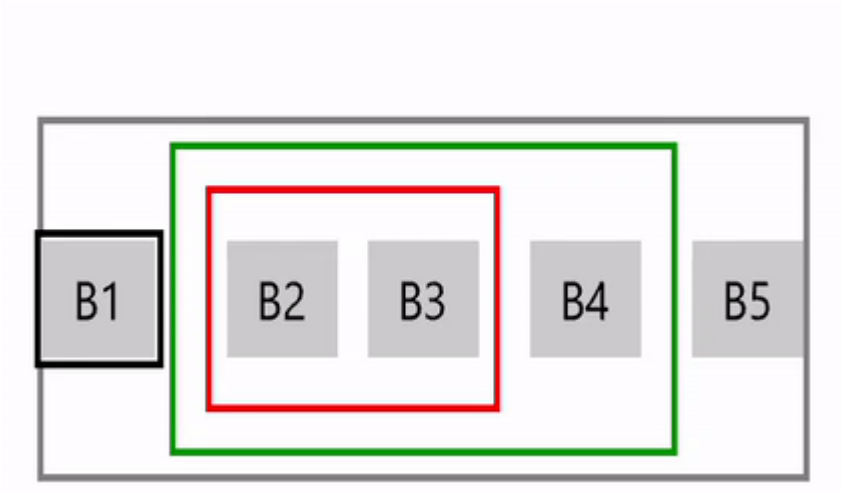
Here's an example of two nested directional areas within an element that does not explicitly support 2D directional navigation. In this case, directional navigation is not supported between the two nested areas.



XYFocusKeyboardNavigation enabled and nested behavior

Here's a more complex example of three nested directional areas where:

- When B1 has focus, only B5 can be navigated to (and vice versa) because there is a directional area boundary where XYFocusKeyboardNavigation set to Disabled, making B2, B3, and B4 unreachable with the arrow keys
- When B2 has focus, only B3 can be navigated to (and vice versa) because the directional area boundary prevents arrow key navigation to B1, B4, and B5
- When B4 has focus, the Tab key must be used to navigate between controls



XYFocusKeyboardNavigation enabled and complex nested behavior

Tab navigation

While the arrow keys can be used for 2D directional navigation witin a control, or control group, the Tab key can be used to navigate between all controls in a Windows application.

All interactive controls support Tab key navigation by default (IsEnabled and IsTabStop property are **true**), with the logical tab order derived from the control layout in your application. However, the default order does not necessarily correspond to the visual order. The actual display position might depend on the parent layout container and certain properties that you can set on the child elements to influence the layout.

Avoid a custom tab order that makes the focus jump around in your application. For example, a list of controls in a form should have a tab order that flows from top to bottom and left to right (depending on locale).

In this section we describe how this tab order can be fully customized to suit your app.

Set the tab navigation behavior

The TabFocusNavigation property of UIElement specifies the tab navigation behavior for its entire object tree (or directional area).

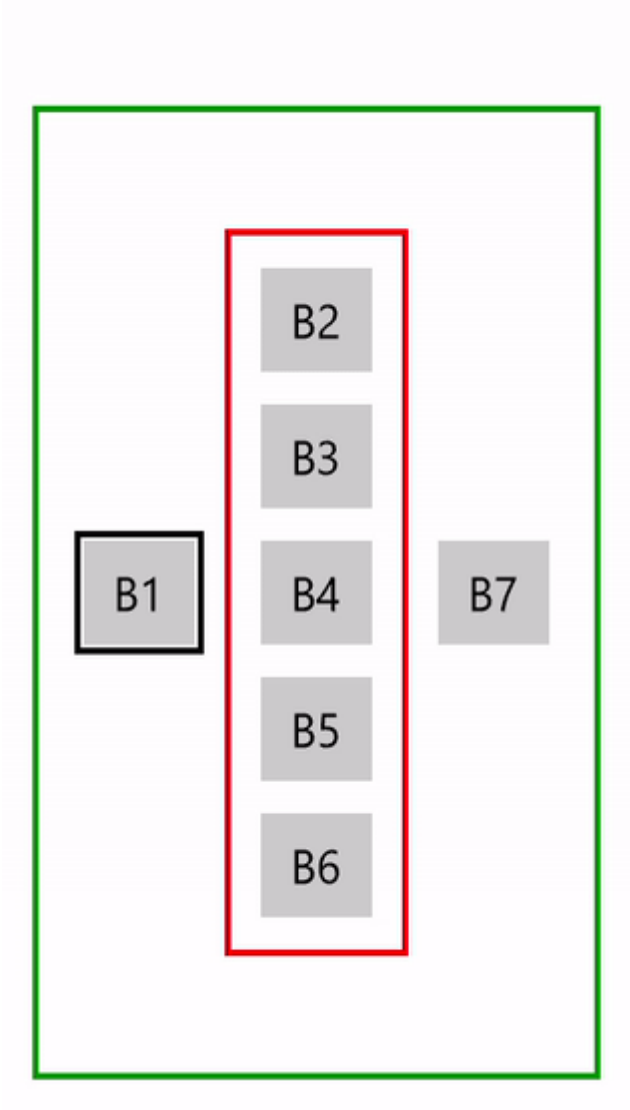
> ⓘ **Note**
>
> Use this property instead of the **Control.TabNavigation** property for objects that do not use a **ControlTemplate** to define their appearance.

As we mentioned in the previous section, to avoid a confusing navigation experience, we recommend that child elements of a directional area *not* be explicitly specified in the tab navigation order of your application. See the UIElement.TabFocusNavigation and the TabIndex properties for more detail on tabbing behavior for an element.

> For versions older than Windows 10 Creators Update (build 10.0.15063), tab settings were limited to ControlTemplate objects. For more info, see Control.TabNavigation.

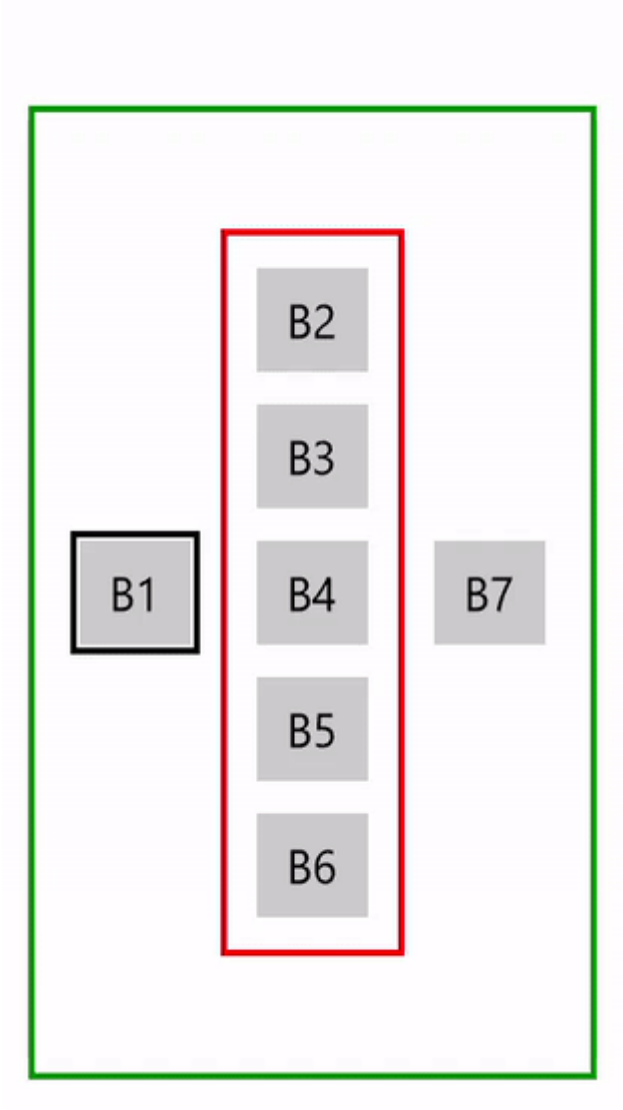
TabFocusNavigation has a value of type KeyboardNavigationMode with the following possible values (note that these examples are not custom control groups and do not require inner navigation with the arrow keys):

- **Local** (default) Tab indexes are recognized on the local subtree inside the container. For this example, the tab order is B1, B2, B3, B4, B5, B6, B7, B1.



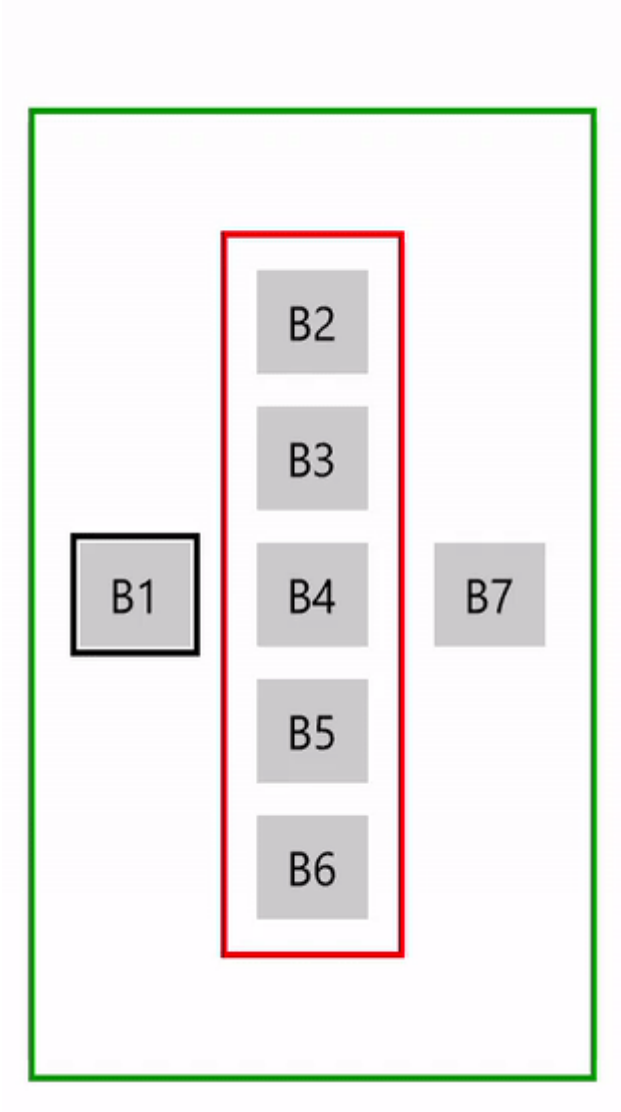
"Local" tab navigation behavior

- **Once** The container and all child elements receive focus once. For this example, the tab order is B1, B2, B7, B1 (inner navigation with arrow key is also demonstrated).



"Once" tab navigation behavior

- **Cycle**
  Focus cycles back to the initial focusable element inside a container. For this example, the tab order is B1, B2, B3, B4, B5, B6, B2...



"Cycle" tab navigation behavior

Here's the code for the preceding examples (with TabFocusNavigation ="Cycle").

XAML

```
<Grid
    Background="{ThemeResource ApplicationPageBackgroundThemeBrush}"
    TabFocusNavigation="Cycle">
    <Grid.RowDefinitions>
        <RowDefinition Height="40"/>
        <RowDefinition Height="300"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <TextBlock Name="KeyPressed"
               Grid.Row="0"
               FontWeight="ExtraBold"
               HorizontalTextAlignment="Center"
               TextWrapping="Wrap"
               Padding="10" />
    <StackPanel Name="ContainerPrimary"
                KeyDown="Container_KeyDown"
                Orientation="Horizontal"
```

```
                HorizontalAlignment="Center"
                BorderBrush="Green"
                BorderThickness="2"
                Grid.Row="1"
                Padding="10"
                MaxWidth="200">
        <Button Name="B1"
                Content="B1"
                GettingFocus="Btn_GettingFocus"
                Margin="5"/>
        <StackPanel Name="ContainerSecondary"
                    KeyDown="Container_KeyDown"
                    XYFocusKeyboardNavigation="Enabled"
                    TabFocusNavigation ="Cycle"
                    Orientation="Vertical"
                    VerticalAlignment="Center"
                    BorderBrush="Red"
                    BorderThickness="2"
                    Padding="5" Margin="5">
            <Button Name="B2"
                    Content="B2"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
            <Button Name="B3"
                    Content="B3"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
            <Button Name="B4"
                    Content="B4"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
            <Button Name="B5"
                    Content="B5"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
            <Button Name="B6"
                    Content="B6"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
        </StackPanel>
        <Button Name="B7"
                Content="B7"
                GettingFocus="Btn_GettingFocus"
                Margin="5"/>
    </StackPanel>
</Grid>
```

TabIndex

Use TabIndex to specify the order in which elements receive focus when the user navigates through controls using the Tab key. A control with a lower tab index receives focus before a control with a higher index.

When a control has no TabIndex specified, it is assigned a higher index value than the current highest index value (and the lowest priority) of all interactive controls in the visual tree, based on scope.

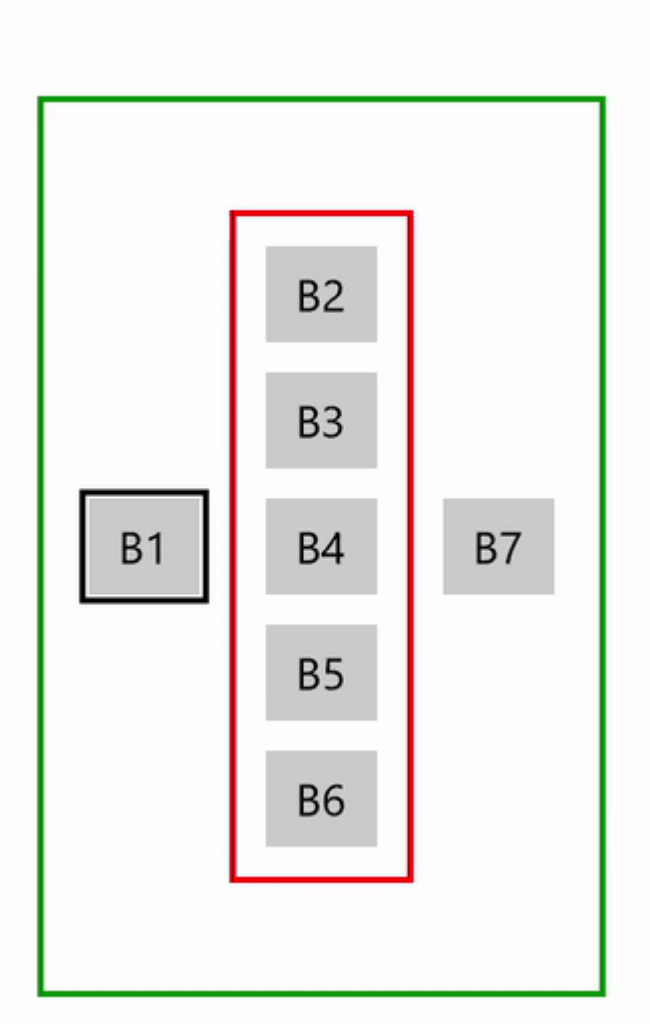
All child elements of a control are considered a scope, and if one of these elements also has child elements, they are considered another scope. Any ambiguity is resolved by choosing the first element on the visual tree of the scope.

To exclude a control from the tab order, set the IsTabStop property to **false**.

Override the default tab order by setting the TabIndex property.

> ⓘ **Note**
>
> **TabIndex** works the same way with both **UIElement.TabFocusNavigation** and **Control.TabNavigation**.

Here, we show how focus navigation can be affected by the TabIndex property on specific elements.



"Local" tab navigation with TabIndex behavior

In the preceding example, there are two scopes:

- B1, directional area (B2 - B6), and B7
- directional area (B2 - B6)

When B3 (in the directional area) gets focus, the scope changes and tab navigation transfers to the directional area where the best candidate for subsequent focus is identified. In this case, B2 followed by B4, B5, and B6. Scope then changes again, and focus moves to B1.

Here's the code for this example.

XAML

```
<Grid
    Background="{ThemeResource ApplicationPageBackgroundThemeBrush}"
    TabFocusNavigation="Cycle">
    <Grid.RowDefinitions>
        <RowDefinition Height="40"/>
        <RowDefinition Height="300"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <TextBlock Name="KeyPressed"
               Grid.Row="0"
               FontWeight="ExtraBold"
               HorizontalTextAlignment="Center"
               TextWrapping="Wrap"
               Padding="10" />
    <StackPanel Name="ContainerPrimary"
                KeyDown="Container_KeyDown"
                Orientation="Horizontal"
                HorizontalAlignment="Center"
                BorderBrush="Green"
                BorderThickness="2"
                Grid.Row="1"
                Padding="10"
                MaxWidth="200">
        <Button Name="B1"
                Content="B1"
                TabIndex="1"
                ToolTipService.ToolTip="TabIndex = 1"
                GettingFocus="Btn_GettingFocus"
                Margin="5"/>
        <StackPanel Name="ContainerSecondary"
                    KeyDown="Container_KeyDown"
                    TabFocusNavigation ="Local"
                    Orientation="Vertical"
                    VerticalAlignment="Center"
                    BorderBrush="Red"
                    BorderThickness="2"
                    Padding="5" Margin="5">
            <Button Name="B2"
```

```
                    Content="B2"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
            <Button Name="B3"
                    Content="B3"
                    TabIndex="3"
                    ToolTipService.ToolTip="TabIndex = 3"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
            <Button Name="B4"
                    Content="B4"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
            <Button Name="B5"
                    Content="B5"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
            <Button Name="B6"
                    Content="B6"
                    GettingFocus="Btn_GettingFocus"
                    Margin="5"/>
        </StackPanel>
        <Button Name="B7"
                Content="B7"
                TabIndex="2"
                ToolTipService.ToolTip="TabIndex = 2"
                GettingFocus="Btn_GettingFocus"
                Margin="5"/>
    </StackPanel>
</Grid>
```

2D directional navigation for keyboard, gamepad, and remote control

Non-pointer input types such as keyboard, gamepad, remote control, and accessibility tools like Windows Narrator, share a common, underlying mechanism for navigating and interacting with the UI of your Windows application.

In this section, we cover how to specify a preferred navigation strategy and fine tune focus navigation within your application through a set of navigation strategy properties that support all focus-based, non-pointer input types.

For more general information on building apps and experiences for Xbox/TV, see Keyboard Interaction, Designing for Xbox and TV, and Gamepad and remote control interactions.

Navigation Strategies

> Navigation strategies are applicable to keyboard, gamepad, remote control, and various accessibility tools.

The following navigation strategy properties let you influence which control receives focus based on the arrow key, directional pad (D-pad) button, or similar pressed.

- XYFocusUpNavigationStrategy
- XYFocusDownNavigationStrategy
- XYFocusLeftNavigationStrategy
- XYFocusRightNavigationStrategy

These properties have possible values of Auto (default), NavigationDirectionDistance, Projection, or RectilinearDistance .

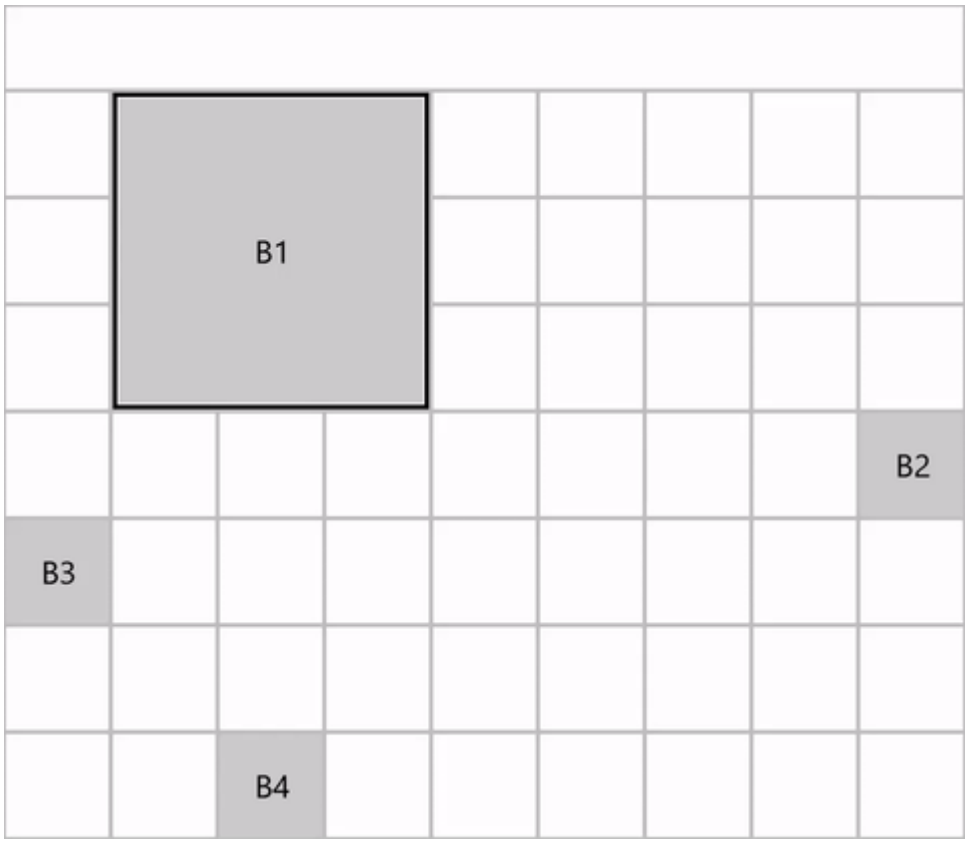
If set to **Auto**, the behavior of the element is based on the ancestors of the element. If all elements are set to **Auto**, **Projection** is used.

> ⓘ **Note**
>
> Other factors, such as the previously focused element or proximity to the axis of the navigation direction, can influence the result.

Projection

The Projection strategy moves focus to the first element encountered when the edge of the currently focused element is *projected* in the direction of navigation.

In this example, each focus navigation direction is set to Projection. Notice how focus moves down from B1 to B4, bypassing B3. This is because, B3 is not in the projection zone. Also notice how a focus candidate is not identified when moving left from B1. This is because the position of B2 relative to B1 eliminates B3 as a candidate. If B3 was in the same row as B2, it would be a viable candidate for left navigation. B2 is a viable candidate due to its unobstructed proximity to the axis of navigation direction.

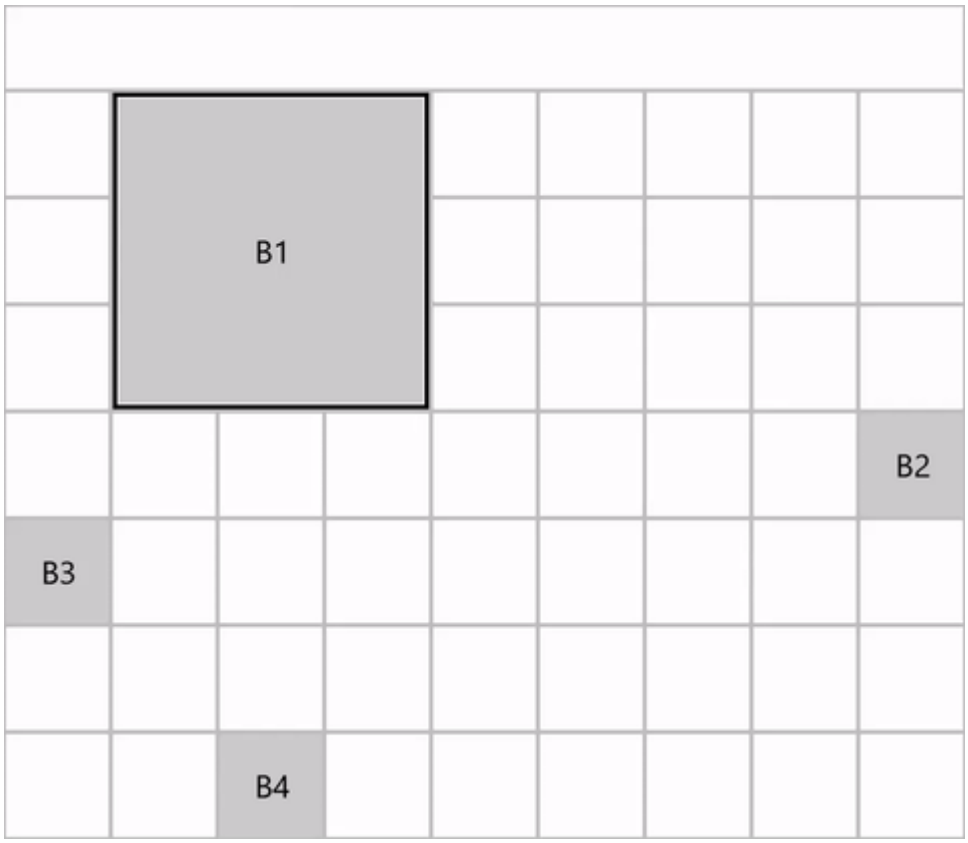


Projection navigation strategy

NavigationDirectionDistance

The NavigationDirectionDistance strategy moves focus to the element closest to the axis of the navigation direction.

The edge of the bounding rect corresponding to the navigation direction is *extended* and *projected* to identify candidate targets. The first element encountered is identified as the target. In the case of multiple candidates, the closest element is identified as the target. If there are still multiple candidates, the topmost/leftmost element is identified as the candidate.

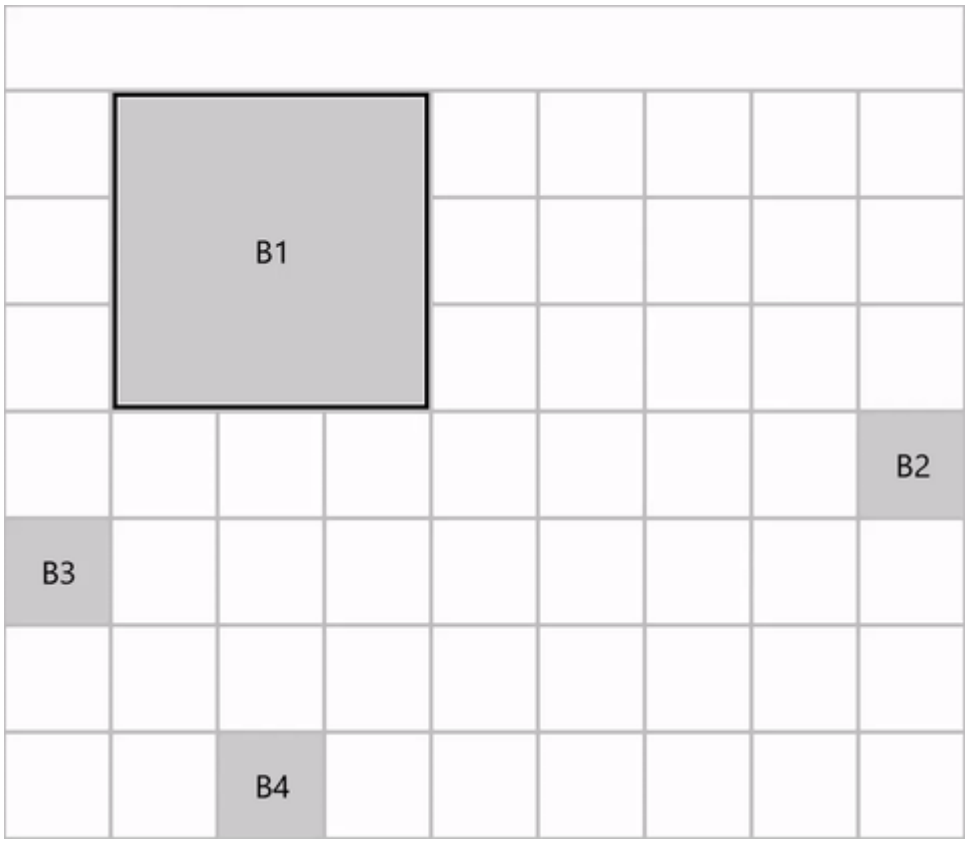


NavigationDirectionDistance navigation strategy

RectilinearDistance

The RectilinearDistance strategy moves focus to the closest element based on 2D rectilinear distance (Taxicab geometry).

The sum of the primary distance and the secondary distance to each potential candidate is used to identify the best candidtate. In a tie, the first element to the left is selected if the requested direction is up or down, and the first element to the top is selected if the requested direction is left or right.



RectilinearDistance navigation strategy

This image shows how, when B1 has focus and down is the requested direction, B3 is the RectilinearDistance focus candidate. This is based on the following calcualations for this example:

- Distance (B1, B3, Down) is 10 + 0 = 10
- Distance (B1, B2, Down) is 0 + 40 = 30
- Distance (B1, D, Down) is 30 + 0 = 30

Programmatic focus navigation

Article • 06/24/2021

To move focus programmatically in your Windows application, you can use either the FocusManager.TryMoveFocus method or the FindNextElement method.

TryMoveFocus attempts to change focus from the element with focus to the next focusable element in the specified direction, while FindNextElement retrieves the element (as a DependencyObject) that will receive focus based on the specified navigation direction (directional navigation only, cannot be used to emulate tab navigation).

> **Note**
>
> We recommend using the **FindNextElement** method instead of **FindNextFocusableElement** because FindNextFocusableElement retrieves a UIElement, which returns null if the next focusable element is not a UIElement (such as a Hyperlink object).

Find a focus candidate within a scope

You can customize the focus navigation behavior for both TryMoveFocus and FindNextElement, including searching for the next focus candidate within a specific UI tree or excluding specific elements from consideration.

This example uses a TicTacToe game to demonstrate the TryMoveFocus and FindNextElement methods.

XAML

```
<StackPanel Orientation="Horizontal"
                VerticalAlignment="Center"
```

```
                HorizontalAlignment="Center" >
    <Button Content="Start Game" />
    <Button Content="Undo Movement" />
    <Grid x:Name="TicTacToeGrid" KeyDown="OnKeyDown">
        <Grid.ColumnDefinitions>
            <ColumnDefinition Width="50" />
            <ColumnDefinition Width="50" />
            <ColumnDefinition Width="50" />
        </Grid.ColumnDefinitions>
        <Grid.RowDefinitions>
            <RowDefinition Height="50" />
            <RowDefinition Height="50" />
            <RowDefinition Height="50" />
        </Grid.RowDefinitions>
        <myControls:TicTacToeCell
            Grid.Column="0" Grid.Row="0"
            x:Name="Cell00" />
        <myControls:TicTacToeCell
            Grid.Column="1" Grid.Row="0"
            x:Name="Cell10"/>
        <myControls:TicTacToeCell
            Grid.Column="2" Grid.Row="0"
            x:Name="Cell20"/>
        <myControls:TicTacToeCell
            Grid.Column="0" Grid.Row="1"
            x:Name="Cell01"/>
        <myControls:TicTacToeCell
            Grid.Column="1" Grid.Row="1"
            x:Name="Cell11"/>
        <myControls:TicTacToeCell
            Grid.Column="2" Grid.Row="1"
            x:Name="Cell21"/>
        <myControls:TicTacToeCell
            Grid.Column="0" Grid.Row="2"
            x:Name="Cell02"/>
        <myControls:TicTacToeCell
            Grid.Column="1" Grid.Row="2"
            x:Name="Cell22"/>
        <myControls:TicTacToeCell
            Grid.Column="2" Grid.Row="2"
            x:Name="Cell32"/>
    </Grid>
</StackPanel>
```

C#

```
private void OnKeyDown(object sender, KeyRoutedEventArgs e)
{
    DependencyObject candidate = null;

    var options = new FindNextElementOptions ()
    {
        SearchRoot = TicTacToeGrid,
```

```
        XYFocusNavigationStrategyOverride =
XYFocusNavigationStrategyOverride.Projection
    };

    switch (e.Key)
    {
        case Windows.System.VirtualKey.Up:
            candidate =
                FocusManager.FindNextElement(
                    FocusNavigationDirection.Up, options);
            break;
        case Windows.System.VirtualKey.Down:
            candidate =
                FocusManager.FindNextElement(
                    FocusNavigationDirection.Down, options);
            break;
        case Windows.System.VirtualKey.Left:
            candidate = FocusManager.FindNextElement(
                FocusNavigationDirection.Left, options);
            break;
        case Windows.System.VirtualKey.Right:
            candidate =
                FocusManager.FindNextElement(
                    FocusNavigationDirection.Right, options);
            break;
    }
    // Also consider whether candidate is a Hyperlink, WebView, or
TextBlock.
    if (candidate != null && candidate is Control)
    {
        (candidate as Control).Focus(FocusState.Keyboard);
    }
}
```

Use FindNextElementOptions to further customize how focus candidates are identified. This object provides the following properties:

- SearchRoot - Scope the search for focus navigation candidates to the children of this DependencyObject. Null indicates to start the search from the root of the visual tree.

> **ⓘ Important**
>
> If one or more transforms are applied to the descendants of **SearchRoot** that place them outside of the directional area, these elements are still considered candidates.

- ExclusionRect - Focus navigation candidates are identified using a "fictitious" bounding rectangle where all overlapping objects are excluded from navigation

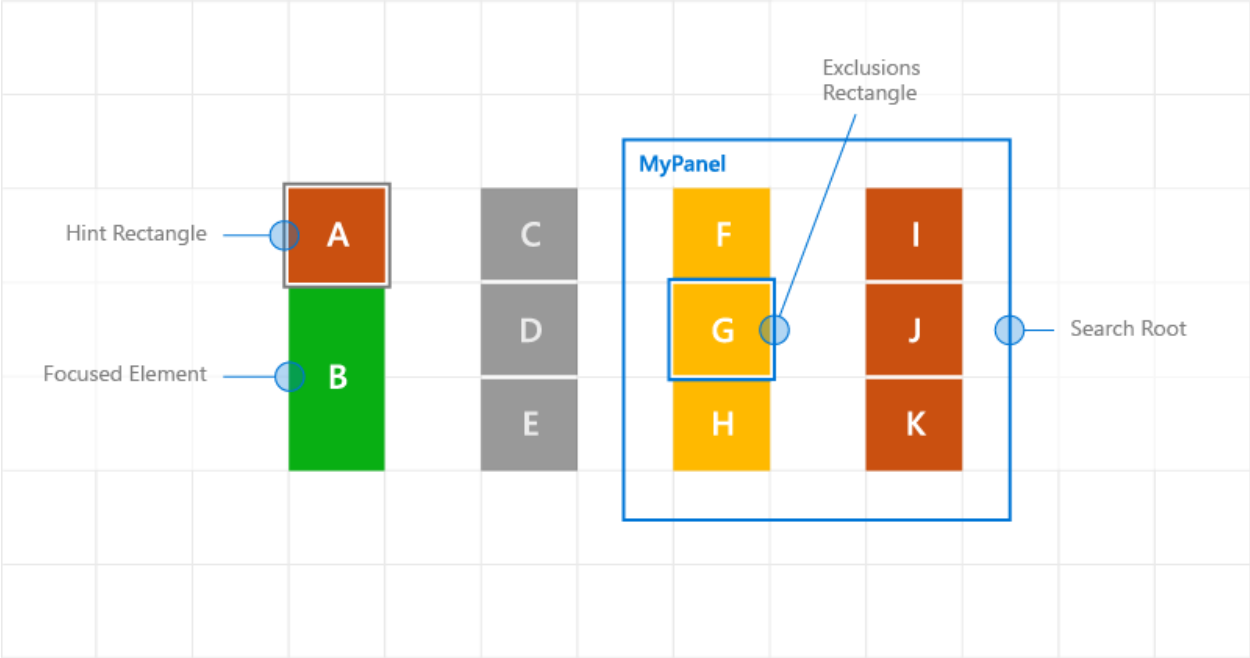
focus. This rectangle is used only for calculations and is never added to the visual tree.

- HintRect - Focus navigation candidates are identified using a "fictitious" bounding rectangle that identifies the elements most likely to receive focus. This rectangle is used only for calculations and is never added to the visual tree.
- XYFocusNavigationStrategyOverride - The focus navigation strategy used to identify the best candidate element to receive focus.

The following image illustrates some of these concepts.

When element B has focus, FindNextElement identifies I as the focus candidate when navigating to the right. The reasons for this are:

- Because of the HintRect on A, the starting reference is A, not B
- C is not a candidate because MyPanel has been specified as the SearchRoot
- F is not a candidate because the ExclusionRect overlaps it



Custom focus navigation behavior using navigation hints

Navigation focus events

NoFocusCandidateFound event

The UIElement.NoFocusCandidateFound event is fired when the tab or arrow keys are pressed and there is no focus candidate in the specified direction. This event is not fired for TryMoveFocus.

Because this is a routed event, it bubbles from the focused element up through successive parent objects to the root of the object tree. This lets you handle the event wherever appropriate.

Here, we show how a Grid opens a SplitView when the user attempts to move focus to the left of the left-most focusable control (see Designing for Xbox and TV).

XAML

```
<Grid NoFocusCandidateFound="OnNoFocusCandidateFound">
...
</Grid>
```

C#

```
private void OnNoFocusCandidateFound (
    UIElement sender, NoFocusCandidateFoundEventArgs args)
{
    if(args.NavigationDirection == FocusNavigationDirection.Left)
    {
        if(args.InputDevice == FocusInputDeviceKind.Keyboard ||
        args.InputDevice == FocusInputDeviceKind.GameController )
            {
                OpenSplitPaneView();
            }
        args.Handled = true;
    }
}
```

GotFocus and LostFocus events

The UIElement.GotFocus and UIElement.LostFocus events are fired when an element gets focus or loses focus, respectively. This event is not fired for TryMoveFocus.

Because these are routed events, they bubble from the focused element up through successive parent objects to the root of the object tree. This lets you handle the event wherever appropriate.

GettingFocus and LosingFocus events

The UIElement.GettingFocus and UIElement.LosingFocus events fire before the respective UIElement.GotFocus and UIElement.LostFocus events.

Because these are routed events, they bubble from the focused element up through successive parent objects to the root of the object tree. As this happens before a focus

change takes place, you can redirect or cancel the focus change.

GettingFocus and LosingFocus are synchronous events so focus won't be moved while these events are bubbling. However, GotFocus and LostFocus are asynchronous events, which means there is no guarantee that focus won't move again before the handler is executed.

If focus moves through a call to Control.Focus, GettingFocus is raised during the call, while GotFocus is raised after the call.

The focus navigation target can be changed during the GettingFocus and LosingFocus events (before focus moves) through the GettingFocusEventArgs.NewFocusedElement property. Even if the target is changed, the event still bubbles and the target can be changed again.

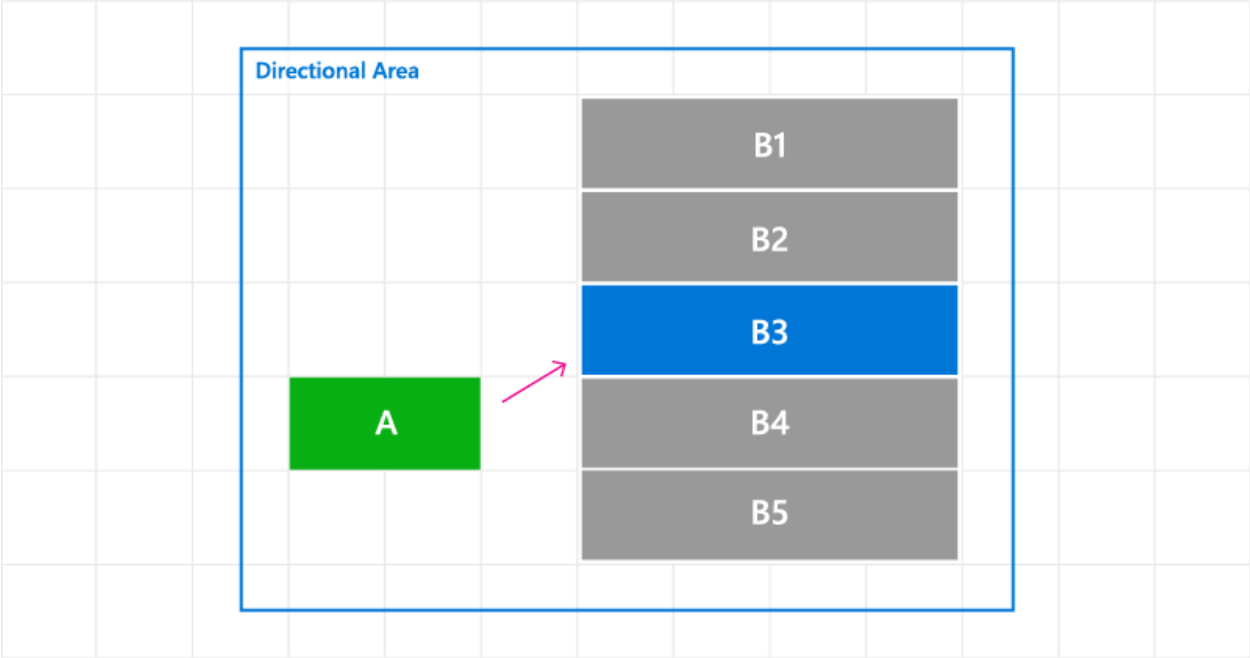
To avoid reentrancy issues, an exception is thrown if you try to move focus (using TryMoveFocus or Control.Focus) while these events are bubbling.

These events are fired regardless of the reason for the focus moving (including tab navigation, directional navigation, and programmatic navigation).

Here is the order of execution for the focus events:

1. LosingFocus If focus is reset back to the losing focus element or TryCancel is successful, no further events are fired.
2. GettingFocus If focus is reset back to the losing focus element or TryCancel is successful, no further events are fired.
3. LostFocus
4. GotFocus

The following image shows how, when moving to the right from A, the XYFocus chooses B4 as a candidate. B4 then fires the GettingFocus event where the ListView has the opportunity to reassign focus to B3.



Changing focus navigation target on GettingFocus event

Here, we show how to handle the GettingFocus event and redirect focus.

XAML

```
<StackPanel Orientation="Horizontal">
    <Button Content="A" />
    <ListView x:Name="MyListView" SelectedIndex="2"
GettingFocus="OnGettingFocus">
        <ListViewItem>LV1</ListViewItem>
        <ListViewItem>LV2</ListViewItem>
        <ListViewItem>LV3</ListViewItem>
        <ListViewItem>LV4</ListViewItem>
        <ListViewItem>LV5</ListViewItem>
    </ListView>
</StackPanel>
```

C#

```
private void OnGettingFocus(UIElement sender, GettingFocusEventArgs args)
{
    //Redirect the focus only when the focus comes from outside of the
ListView.
    // move the focus to the selected item
    if (MyListView.SelectedIndex != -1 &&
        IsNotAChildOf(MyListView, args.OldFocusedElement))
    {
        var selectedContainer =
            MyListView.ContainerFromItem(MyListView.SelectedItem);
        if (args.FocusState ==
            FocusState.Keyboard &&
            args.NewFocusedElement != selectedContainer)
        {
```

```
            args.TryRedirect(
                MyListView.ContainerFromItem(MyListView.SelectedItem));
            args.Handled = true;
        }
    }
}
```

Here, we show how to handle the LosingFocus event for a CommandBar and set focus when the menu is closed.

XAML

```
<CommandBar x:Name="MyCommandBar" LosingFocus="OnLosingFocus">
     <AppBarButton Icon="Back" Label="Back" />
     <AppBarButton Icon="Stop" Label="Stop" />
     <AppBarButton Icon="Play" Label="Play" />
     <AppBarButton Icon="Forward" Label="Forward" />

     <CommandBar.SecondaryCommands>
         <AppBarButton Icon="Like" Label="Like" />
         <AppBarButton Icon="Share" Label="Share" />
     </CommandBar.SecondaryCommands>
 </CommandBar>
```

C#

```
private void OnLosingFocus(UIElement sender, LosingFocusEventArgs args)
{
    if (MyCommandBar.IsOpen == true &&
        IsNotAChildOf(MyCommandBar, args.NewFocusedElement))
    {
        if (args.TryCancel())
        {
            args.Handled = true;
        }
    }
}
```

Find the first and last focusable element

The FocusManager.FindFirstFocusableElement and FocusManager.FindLastFocusableElement methods move focus to the first or last focusable element within the scope of an object (the element tree of a UIElement or the text tree of a TextElement). The scope is specified in the call (if the argument is null, the scope is the current window).

If no focus candidates can be identified in the scope, null is returned.

Here, we show how to specify that the buttons of a CommandBar have a wrap-around directional behavior (see Keyboard Interactions).

XAML

```
<CommandBar x:Name="MyCommandBar" LosingFocus="OnLosingFocus">
    <AppBarButton Icon="Back" Label="Back" />
    <AppBarButton Icon="Stop" Label="Stop" />
    <AppBarButton Icon="Play" Label="Play" />
    <AppBarButton Icon="Forward" Label="Forward" />

    <CommandBar.SecondaryCommands>
        <AppBarButton Icon="Like" Label="Like" />
        <AppBarButton Icon="ReShare" Label="Share" />
    </CommandBar.SecondaryCommands>
</CommandBar>
```

C#

```
private void OnLosingFocus(UIElement sender, LosingFocusEventArgs args)
{
    if (IsNotAChildOf(MyCommandBar, args.NewFocussedElement))
    {
        DependencyObject candidate = null;
        if (args.Direction == FocusNavigationDirection.Left)
        {
            candidate = FocusManager.FindLastFocusableElement(MyCommandBar);
        }
        else if (args.Direction == FocusNavigationDirection.Right)
        {
            candidate =
FocusManager.FindFirstFocusableElement(MyCommandBar);
        }
        if (candidate != null)
        {
            args.NewFocusedElement = candidate;
            args.Handled = true;
        }
    }
}
```

Respond to the presence of the touch keyboard

Article • 06/24/2021

Learn how to tailor the UI of your app when showing or hiding the touch keyboard.

Important APIs

- AutomationPeer
- InputPane

The touch keyboard in default layout mode

The touch keyboard enables text entry for devices that support touch. Windows app text input controls invoke the touch keyboard by default when a user taps on an editable input field. The touch keyboard typically remains visible while the user navigates between controls in a form, but this behavior can vary based on the other control types within the form.

To support corresponding touch keyboard behavior in a custom text input control that does not derive from a standard text input control, you must use the AutomationPeer class to expose your controls to Microsoft UI Automation and implement the correct UI Automation control patterns. See Keyboard accessibility and Custom automation peers.

Once this support has been added to your custom control, you can respond appropriately to the presence of the touch keyboard.

Prerequisites:

This topic builds on Keyboard interactions.

You should have a basic understanding of standard keyboard interactions, handling keyboard input and events, and UI Automation.

If you're new to developing Windows apps, have a look through these topics to get familiar with the technologies discussed here.

- Create your first app
- Learn about events with Events and routed events overview

User experience guidelines:

For helpful tips about designing a useful and engaging app optimized for keyboard input, see Keyboard interactions .

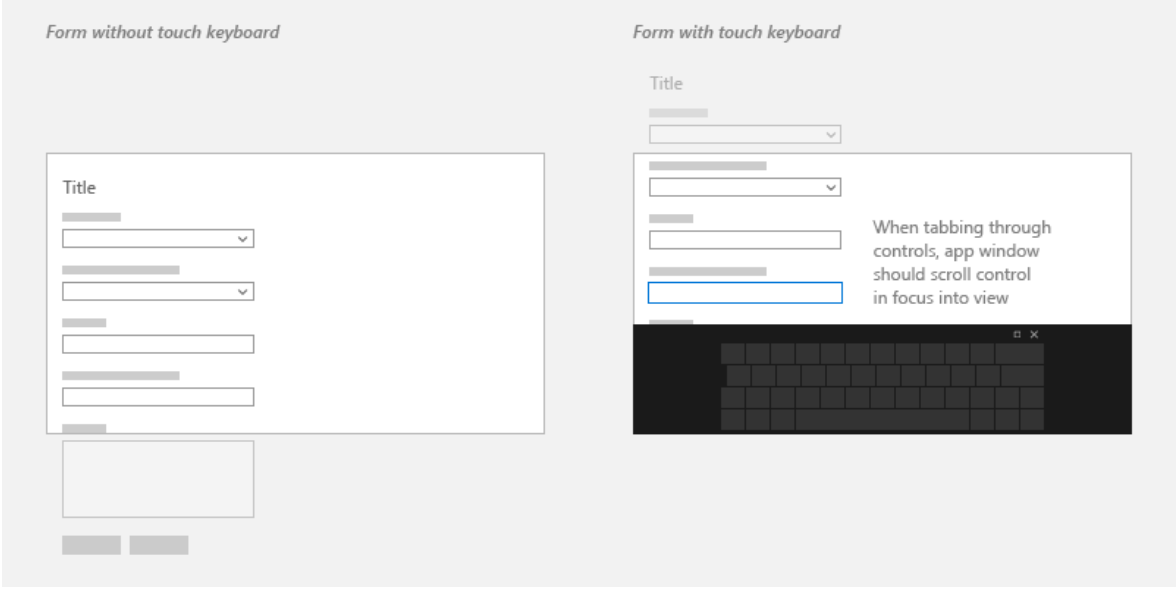
Touch keyboard and a custom UI

Here are a few basic recommendations for custom text input controls.

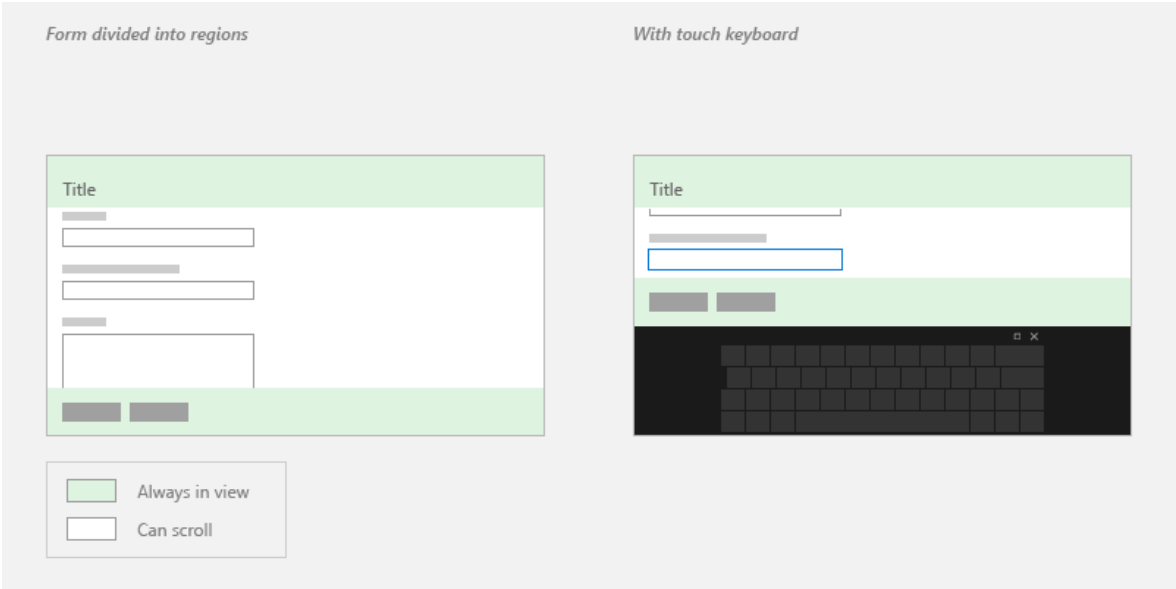
- Display the touch keyboard throughout the entire interaction with your form.
- Ensure that your custom controls have the appropriate UI Automation AutomationControlType for the keyboard to persist when focus moves from a text input field while in the context of text entry. For example, if you have a menu that's opened in the middle of a text-entry scenario, and you want the keyboard to persist, the menu must have the **AutomationControlType** of Menu.
- Don't manipulate UI Automation properties to control the touch keyboard. Other accessibility tools rely on the accuracy of UI Automation properties.
- Ensure that users can always see the input field that they're interacting with.

  Because the touch keyboard occludes a large portion of the screen, Windows ensures that the input field with focus scrolls into view as a user navigates through the controls on the form, including controls that are not currently in view.

  When customizing your UI, provide similar behavior on the appearance of the touch keyboard by handling the Showing and Hiding events exposed by the **InputPane** object.



In some cases, there are UI elements that should stay on the screen the entire time. Design the UI so that the form controls are contained in a panning region and the important UI elements are static. For example:



Handling the Showing and Hiding events

Here's an example of attaching event handlers for the Showing and Hiding events of the touch keyboard.

C#

```
using Windows.UI.ViewManagement;
using Windows.UI.Xaml.Controls;
using Windows.UI.Xaml.Media;
using Windows.Foundation;
using Windows.UI.Xaml.Navigation;

namespace SDKTemplate
```

```
{
    /// <summary>
    /// Sample page to subscribe show/hide event of Touch Keyboard.
    /// </summary>
    public sealed partial class Scenario2_ShowHideEvents : Page
    {
        public Scenario2_ShowHideEvents()
        {
            this.InitializeComponent();
        }

        protected override void OnNavigatedTo(NavigationEventArgs e)
        {
            InputPane currentInputPane = InputPane.GetForCurrentView();
            // Subscribe to Showing/Hiding events
            currentInputPane.Showing += OnShowing;
            currentInputPane.Hiding += OnHiding;
        }

        protected override void OnNavigatedFrom(NavigationEventArgs e)
        {
            InputPane currentInputPane = InputPane.GetForCurrentView();
            // Unsubscribe from Showing/Hiding events
            currentInputPane.Showing -= OnShowing;
            currentInputPane.Hiding -= OnHiding;
        }

        void OnShowing(InputPane sender, InputPaneVisibilityEventArgs e)
        {
            LastInputPaneEventRun.Text = "Showing";
        }

        void OnHiding(InputPane sender, InputPaneVisibilityEventArgs e)
        {
            LastInputPaneEventRun.Text = "Hiding";
        }
    }
}
```

C++/WinRT

```
...
#include <winrt/Windows.UI.ViewManagement.h>
...
private:
    winrt::event_token m_showingEventToken;
    winrt::event_token m_hidingEventToken;
...
Scenario2_ShowHideEvents::Scenario2_ShowHideEvents()
{
    InitializeComponent();
}
```

```
void
Scenario2_ShowHideEvents::OnNavigatedTo(Windows::UI::Xaml::Navigation::Navig
ationEventArgs const& e)
{
    auto inputPane{
Windows::UI::ViewManagement::InputPane::GetForCurrentView() };
    // Subscribe to Showing/Hiding events
    m_showingEventToken = inputPane.Showing({ this,
&Scenario2_ShowHideEvents::OnShowing });
    m_hidingEventToken = inputPane.Hiding({ this,
&Scenario2_ShowHideEvents::OnHiding });
}

void
Scenario2_ShowHideEvents::OnNavigatedFrom(Windows::UI::Xaml::Navigation::Nav
igationEventArgs const& e)
{
    auto inputPane{
Windows::UI::ViewManagement::InputPane::GetForCurrentView() };
    // Unsubscribe from Showing/Hiding events
    inputPane.Showing(m_showingEventToken);
    inputPane.Hiding(m_hidingEventToken);
}

void
Scenario2_ShowHideEvents::OnShowing(Windows::UI::ViewManagement::InputPane
const& /*sender*/, Windows::UI::ViewManagement::InputPaneVisibilityEventArgs
const& /*args*/)
{
    LastInputPaneEventRun().Text(L"Showing");
}

void
Scenario2_ShowHideEvents::OnHiding(Windows::UI::ViewManagement::InputPane
const& /*sender*/, Windows::UI::ViewManagement::InputPaneVisibilityEventArgs
const& /*args*/)
{
    LastInputPaneEventRun().Text(L"Hiding");
}
```

C++

```
#include "pch.h"
#include "Scenario2_ShowHideEvents.xaml.h"

using namespace SDKTemplate;
using namespace Platform;
using namespace Windows::Foundation;
using namespace Windows::UI::ViewManagement;
using namespace Windows::UI::Xaml;
using namespace Windows::UI::Xaml::Controls;
using namespace Windows::UI::Xaml::Navigation;
```

```
Scenario2_ShowHideEvents::Scenario2_ShowHideEvents()
{
    InitializeComponent();
}

void Scenario2_ShowHideEvents::OnNavigatedTo(NavigationEventArgs^ e)
{
    auto inputPane = InputPane::GetForCurrentView();
    // Subscribe to Showing/Hiding events
    showingEventToken = inputPane->Showing +=
        ref new TypedEventHandler<InputPane^, InputPaneVisibilityEventArgs^>
(this, &Scenario2_ShowHideEvents::OnShowing);
    hidingEventToken = inputPane->Hiding +=
        ref new TypedEventHandler<InputPane^, InputPaneVisibilityEventArgs^>
(this, &Scenario2_ShowHideEvents::OnHiding);
}

void Scenario2_ShowHideEvents::OnNavigatedFrom(NavigationEventArgs^ e)
{
    auto inputPane =
Windows::UI::ViewManagement::InputPane::GetForCurrentView();
    // Unsubscribe from Showing/Hiding events
    inputPane->Showing -= showingEventToken;
    inputPane->Hiding -= hidingEventToken;
}

void Scenario2_ShowHideEvents::OnShowing(InputPane^ /*sender*/,
InputPaneVisibilityEventArgs^ /*args*/)
{
    LastInputPaneEventRun->Text = L"Showing";
}

void Scenario2_ShowHideEvents::OnHiding(InputPane^ /*sender*/,
InputPaneVisibilityEventArgs ^ /*args*/)
{
    LastInputPaneEventRun->Text = L"Hiding";
}
```

Use input scope to change the touch keyboard

Article • 06/24/2021

To help users to enter data using the touch keyboard, or Soft Input Panel (SIP), you can set the input scope of the text control to match the kind of data the user is expected to enter.

Important APIs

- InputScope
- InputScopeNameValue

The touch keyboard can be used for text entry when your app runs on a device with a touch screen. The touch keyboard is invoked when the user taps on an editable input field, such as a **TextBox** or **RichEditBox**. You can make it much faster and easier for users to enter data in your app by setting the *input scope* of the text control to match the kind of data you expect the user to enter. The input scope provides a hint to the system about the type of text input expected by the control so the system can provide a specialized touch keyboard layout for the input type.

For example, if a text box is used only to enter a 4-digit PIN, set the **InputScope** property to **Number**. This tells the system to show the number keypad layout, which makes it easier for the user to enter the PIN.

> ⓘ **Important**
>
> - This info applies only to the SIP. It does not apply to hardware keyboards or the On-Screen Keyboard available in the Windows Ease of Access options.
> - The input scope does not cause any input validation to be performed, and does not prevent the user from providing any input through a hardware keyboard or other input device. You are still responsible for validating the input in your code as needed.

Changing the input scope of a text control

The input scopes that are available to your app are members of the InputScopeNameValue enumeration. You can set the **InputScope** property of a TextBox

or RichEditBox to one of these values.

> **ⓘ Important**
>
> The InputScope property on PasswordBox supports only the **Password** and **NumericPin** values. Any other value is ignored.

Here, you change the input scope of several text boxes to match the expected data for each text box.

To change the input scope in XAML

1. In the XAML file for your page, locate the tag for the text control that you want to change.
2. Add the InputScope attribute to the tag and specify the InputScopeNameValue value that matches the expected input.

   Here are some text boxes that might appear on a common customer-contact form. With the InputScope set, a touch keyboard with a suitable layout for the data shows for each text box.

   XAML

   ```
   <StackPanel Width="300">
       <TextBox Header="Name" InputScope="Default"/>
       <TextBox Header="Email Address" InputScope="EmailSmtpAddress"/>
       <TextBox Header="Telephone Number" InputScope="TelephoneNumber"/>
       <TextBox Header="Web site" InputScope="Url"/>
   </StackPanel>
   ```

To change the input scope in code

1. In the XAML file for your page, locate the tag for the text control that you want to change. If it's not set, set the x:Name attribute so you can reference the control in your code.

   C#

   ```
   <TextBox Header="Telephone Number" x:Name="phoneNumberTextBox"/>
   ```

2. Instantiate a new InputScope object.

   C#

```
InputScope scope = new InputScope();
```

3. Instantiate a new **InputScopeName** object.

```
C#

InputScopeName scopeName = new InputScopeName();
```

4. Set the **NameValue** property of the **InputScopeName** object to a value of the **InputScopeNameValue** enumeration.

```
C#

scopeName.NameValue = InputScopeNameValue.TelephoneNumber;
```

5. Add the **InputScopeName** object to the **Names** collection of the **InputScope** object.

```
C#

scope.Names.Add(scopeName);
```

6. Set the **InputScope** object as the value of the text control's **InputScope** property.

```
C#

phoneNumberTextBox.InputScope = scope;
```

Here's the code all together.

```
CSharp

InputScope scope = new InputScope();
InputScopeName scopeName = new InputScopeName();
scopeName.NameValue = InputScopeNameValue.TelephoneNumber;
scope.Names.Add(scopeName);
phoneNumberTextBox.InputScope = scope;
```

The same steps can be condensed into this shorthand code.

```
CSharp

phoneNumberTextBox.InputScope = new InputScope()
{
```

```
    Names = {new InputScopeName(InputScopeNameValue.TelephoneNumber)}
};
```

Text prediction, spell checking, and auto-correction

The TextBox and RichEditBox controls have several properties that influence the behavior of the SIP. To provide the best experience for your users, it's important to understand how these properties affect text input using touch.

- IsSpellCheckEnabled—When spell check is enabled for a text control, the control interacts with the system's spell-check engine to mark words that are not recognized. You can tap a word to see a list of suggested corrections. Spell checking is enabled by default.

  For the **Default** input scope, this property also enables automatic capitalization of the first word in a sentence and auto-correction of words as you type. These auto-correction features might be disabled in other input scopes. For more info, see the tables later in this topic.

- IsTextPredictionEnabled—When text prediction is enabled for a text control, the system shows a list of words that you might be beginning to type. You can select from the list so you don't have to type the whole word. Text prediction is enabled by default.

  Text prediction might be disabled if the input scope is other than **Default**, even if the IsTextPredictionEnabled property is **true**. For more info, see the tables later in this topic.

- PreventKeyboardDisplayOnProgrammaticFocus—When this property is **true**, it prevents the system from showing the SIP when focus is programmatically set on a text control. Instead, the keyboard is shown only when the user interacts with the control.

Touch keyboard index for Windows

These tables show the Windows Soft Input Panel (SIP) layouts for common input scope values. The effect of the input scope on the features enabled by the **IsSpellCheckEnabled** and **IsTextPredictionEnabled** properties is listed for each input scope. This is not a comprehensive list of available input scopes.

> **Tip**
>
> You can toggle most touch keyboards between an alphabetic layout and a numbers-and-symbols layout by pressing the **&123** key to change to the numbers-and-symbols layout, and press the **abcd** key to change to the alphabetic layout.

Default

`<TextBox InputScope="Default"/>`

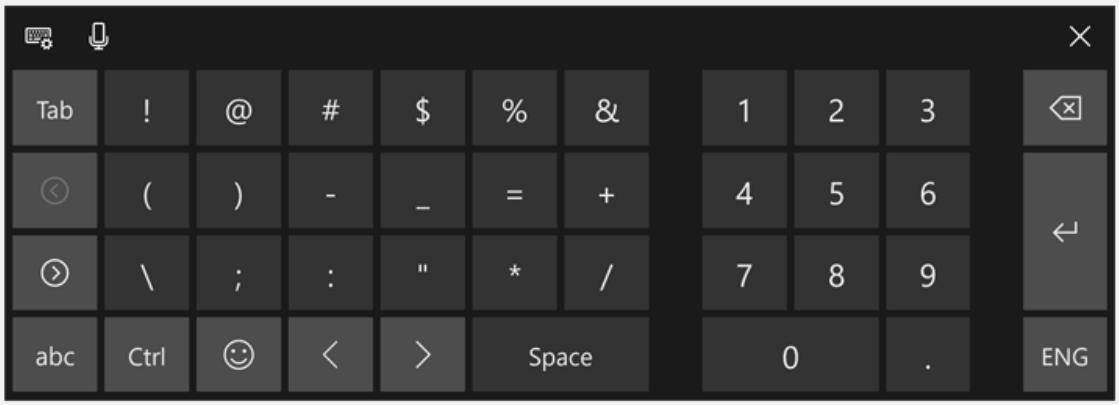
The default Windows touch keyboard.

- Spell check: enabled if **IsSpellCheckEnabled** = **true**, disabled if **IsSpellCheckEnabled** = **false**
- Auto-correction: enabled if **IsSpellCheckEnabled** = **true**, disabled if **IsSpellCheckEnabled** = **false**
- Automatic capitalization: enabled if **IsSpellCheckEnabled** = **true**, disabled if **IsSpellCheckEnabled** = **false**
- Text prediction: enabled if **IsTextPredictionEnabled** = **true**, disabled if **IsTextPredictionEnabled** = **false**

CurrencyAmountAndSymbol

`<TextBox InputScope="CurrencyAmountAndSymbol"/>`

The default numbers and symbols keyboard layout.



- Includes page left/right keys to show more symbols
- Spell check: on by default, can be disabled
- Auto-correction: on by default, can be disabled
- Automatic capitalization: always disabled
- Text prediction: on by default, can be disabled

Url

`<TextBox InputScope="Url"/>`

- Includes the **.com** and → (Go) keys. Press and hold the **.com** key to display additional options (**.org**, **.net**, and region-specific suffixes)
- Includes the **:**, **-**, and **/** keys
- Spell check: off by default, can be enabled
- Auto-correction: off by default, can be enabled

- Automatic capitalization: off by default, can be enabled
- Text prediction: off by default, can be enabled

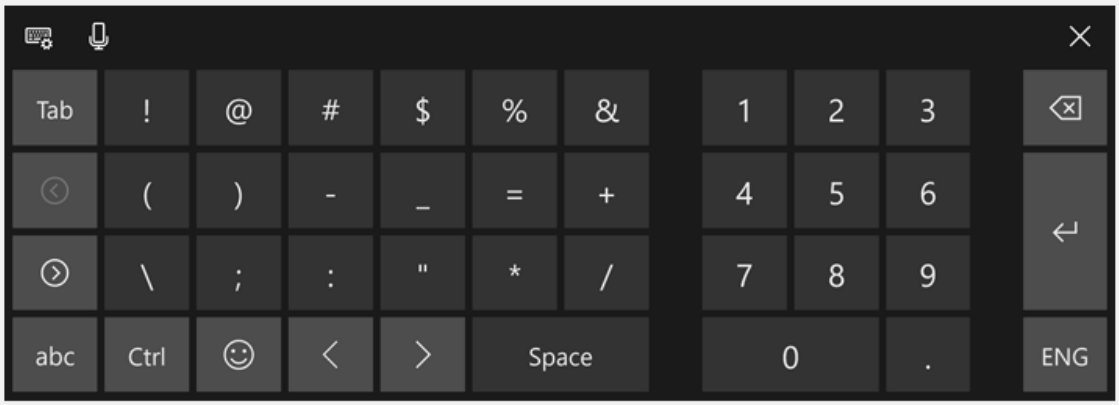
EmailSmtpAddress

```
<TextBox InputScope="EmailSmtpAddress"/>
```

- Includes the @ and **.com** keys. Press and hold the **.com** key to display additional options (**.org**, **.net**, and region-specific suffixes)
- Includes the _ and - keys
- Spell check: off by default, can be enabled
- Auto-correction: off by default, can be enabled
- Automatic capitalization: off by default, can be enabled
- Text prediction: off by default, can be enabled

Number

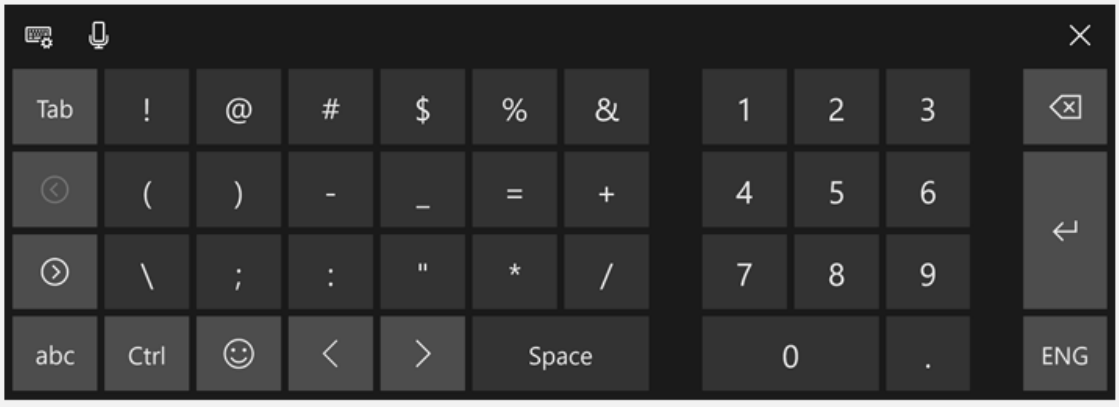
```
<TextBox InputScope="Number"/>
```



- Spell check: on by default, can be disabled
- Auto-correction: on by default, can be disabled
- Automatic capitalization: always disabled
- Text prediction: on by default, can be disabled

TelephoneNumber

`<TextBox InputScope="TelephoneNumber"/>`



- Spell check: on by default, can be disabled
- Auto-correction: on by default, can be disabled
- Automatic capitalization: always disabled
- Text prediction: on by default, can be disabled

Search

`<TextBox InputScope="Search"/>`

- Includes the **Search** key instead of the **Enter** key
- Spell check: on by default, can be disabled
- Auto-correction: on by default, can be disabled
- Auto-capitalization: always disabled
- Text prediction: on by default, can be disabled

SearchIncremental

`<TextBox InputScope="SearchIncremental"/>`

- Same layout as **Default**

- Spell check: off by default, can be enabled
- Auto-correction: always disabled
- Automatic capitalization: always disabled
- Text prediction: always disabled

Formula

```
<TextBox InputScope="Formula"/>
```

- Includes the = key
- Also includes the %, $, and + keys
- Spell check: on by default, can be disabled
- Auto-correction: on by default, can be disabled
- Automatic capitalization: always disabled
- Text prediction: on by default, can be disabled

Chat

```
<TextBox InputScope="Chat"/>
```

- Same layout as **Default**
- Spell check: on by default, can be disabled
- Auto-correction: on by default, can be disabled
- Automatic capitalization: on by default, can be disabled
- Text prediction: on by default, can be disabled

NameOrPhoneNumber

```
<TextBox InputScope="NameOrPhoneNumber"/>
```

- Same layout as **Default**
- Spell check: off by default, can be enabled
- Auto-correction: off by default, can be enabled
- Automatic capitalization: off by default, can be enabled (first letter of each word is capitalized)

- Text prediction: off by default, can be enabled

Custom text input

Article • 06/24/2021

The core text APIs in the **Windows.UI.Text.Core** namespace enable a Windows app to receive text input from any text service supported on Windows devices. The APIs are similar to the Text Services Framework APIs in that the app is not required to have detailed knowledge of the text services. This enables the app to receive text in any language and from any input type, like keyboard, speech, or pen.

> **Important APIs**: **Windows.UI.Text.Core**, **CoreTextEditContext**

Why use core text APIs?

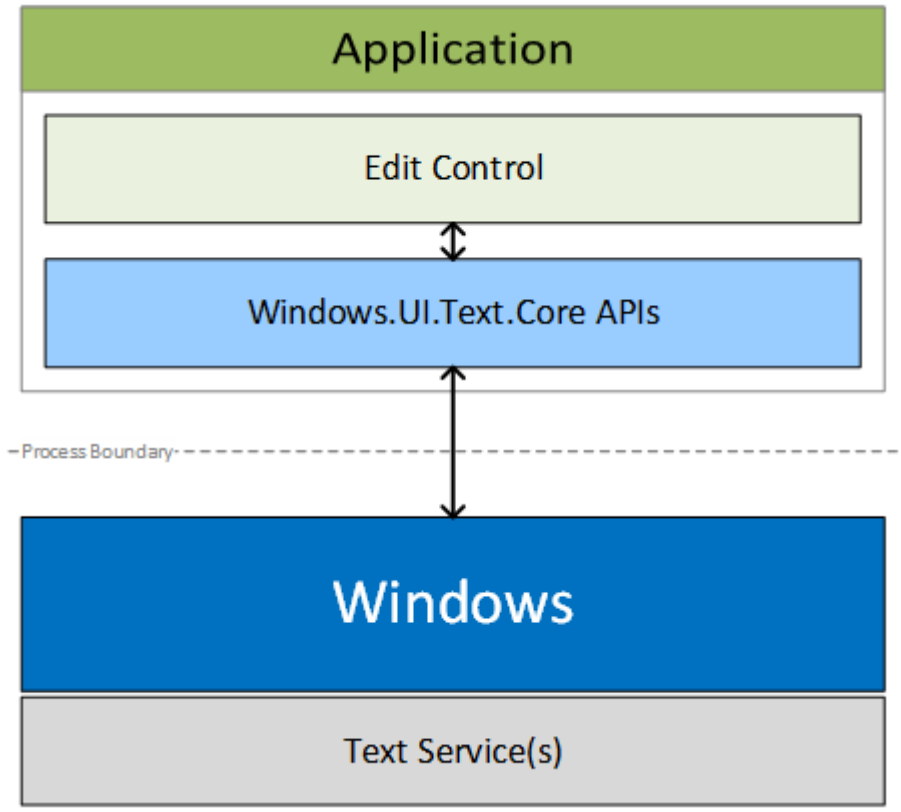
For many apps, the XAML or HTML text box controls are sufficient for text input and editing. However, if your app handles complex text scenarios, like a word processing app, you might need the flexibility of a custom text edit control. You could use the **CoreWindow** keyboard APIs to create your text edit control, but these don't provide a way to receive composition-based text input, which is required to support East Asian languages.

Instead, use the **Windows.UI.Text.Core** APIs when you need to create a custom text edit control. These APIs are designed to give you a lot of flexibility in processing text input, in any language, and let you provide the text experience best suited to your app. Text input and edit controls built with the core text APIs can receive text input from all existing text input methods on Windows devices, from Text Services Framework based Input Method Editors (IMEs) and handwriting on PCs to the WordFlow keyboard (which provides auto-correction, prediction, and dictation) on mobile devices.

Architecture

The following is a simple representation of the text input system.

- "Application" represents a Windows app hosting a custom edit control built using the core text APIs.
- The **Windows.UI.Text.Core** APIs facilitate the communication with text services through Windows. Communication between the text edit control and the text services is handled primarily through a **CoreTextEditContext** object that provides the methods and events to facilitate the communication.



Text ranges and selection

Edit controls provide space for text entry and users expect to edit text anywhere in this space. Here, we explain the text positioning system used by the core text APIs and how ranges and selections are represented in this system.

Application caret position

Text ranges used with the core text APIs are expressed in terms of caret positions. An "Application Caret Position (ACP)" is a zero-based number that indicates the count of characters from the start of the text stream immediately before the caret, as shown here.

Text Stream	H	e	l	l	o	_	W	o	r	l	d
ACP	0	1	2	3	4	5	6	7	8	9	10	11

Text ranges and selection

Text ranges and selections are represented by the CoreTextRange structure which contains two fields:

Field	Data type	Description

Field	Data type	Description
StartCaretPosition	**Number** [JavaScript] | **System.Int32** [.NET] | **int32** [C++]	The start position of a range is the ACP immediately before the first character.
EndCaretPosition	**Number** [JavaScript] | **System.Int32** [.NET] | **int32** [C++]	The end position of a range is the ACP immediately after the last character.

For example, in the text range shown previously, the range [0, 5] specifies the word "Hello". **StartCaretPosition** must always be less than or equal to the **EndCaretPosition**. The range [5, 0] is invalid.

Insertion point

The current caret position, frequently referred to as the insertion point, is represented by setting the **StartCaretPosition** to be equal to the **EndCaretPosition**.

Noncontiguous selection

Some edit controls support noncontiguous selections. For example, Microsoft Office apps support multiple arbitrary selections, and many source code editors support column selection. However, the core text APIs do not support non-contiguous selections. Edit controls must report only a single contiguous selection, most often the active sub-range of the noncontiguous selections.

For example, the following image shows a text stream with two non-contiguous selections: [0, 1] and [6, 11] for which the edit control must report only one (either [0, 1] or [6, 11]).

Working with text

The CoreTextEditContext class enables text flow between Windows and edit controls through the TextUpdating event, the TextRequested event, and the NotifyTextChanged method.

Your edit control receives text through TextUpdating events that are generated when users interact with text input methods like keyboards, speech, or IMEs.

When you change text in your edit control, for example, by pasting text into the control, you need to notify Windows by calling NotifyTextChanged.

If the text service requires the new text, then a TextRequested event is raised. You must provide the new text in the **TextRequested** event handler.

Accepting text updates

Your edit control should typically accept text update requests because they represent the text the user wants to enter. In the TextUpdating event handler, these actions are expected of your edit control:

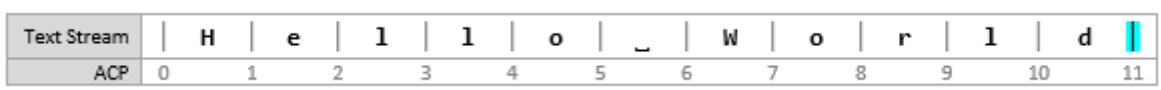
1. Insert the text specified in CoreTextTextUpdatingEventArgs.Text in the position specified in CoreTextTextUpdatingEventArgs.Range.
2. Place selection at the position specified in CoreTextTextUpdatingEventArgs.NewSelection.
3. Notify the system that the update succeeded by setting CoreTextTextUpdatingEventArgs.Result to CoreTextTextUpdatingResult.Succeeded.

For example, this is the state of an edit control before the user types "d". The insertion point is at [10, 10].

When the user types "d", a TextUpdating event is raised with the following CoreTextTextUpdatingEventArgs data:

- Range = [10, 10]
- Text = "d"
- NewSelection = [11, 11]

In your edit control, apply the specified changes and set Result to **Succeeded**. Here's the state of the control after the changes are applied.



Rejecting text updates

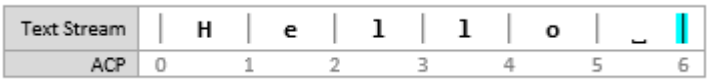
Sometimes, you cannot apply text updates because the requested range is in an area of the edit control that should not be changed. In this case, you should not apply any changes. Instead, notify the system that the update failed by setting CoreTextTextUpdatingEventArgs.Result to CoreTextTextUpdatingResult.Failed.

For example, consider an edit control that accepts only an e-mail address. Spaces should be rejected because e-mail addresses cannot contain spaces, so when TextUpdating events are raised for the space key, you should simply set Result to **Failed** in your edit control.

Notifying text changes

Sometimes, your edit control makes changes to text such as when text is pasted or auto-corrected. In these cases, you must notify the text services of these changes by calling the NotifyTextChanged method.

For example, this is the state of an edit control before the user pastes "World". The insertion point is at [6, 6].



The user performs the paste action and the edit control after the changes are applied:

When this happens, you should call NotifyTextChanged with these arguments:

- *modifiedRange* = [6, 6]
- *newLength* = 5
- *newSelection* = [11, 11]

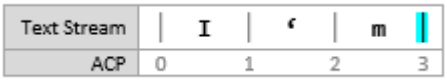
One or more TextRequested events will follow, which you handle to update the text that the text services are working with.

Overriding text updates

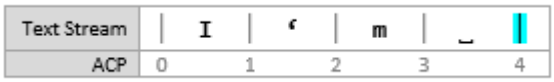
In your edit control, you might want to override a text update to provide auto-correction features.

For example, consider an edit control that provides a correction feature that formalizes contractions. This is the state of the edit control before the user types the space key to

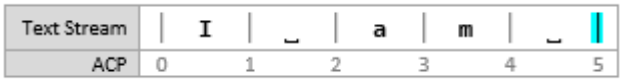
trigger the correction. The insertion point is at [3, 3].



The user presses the space key and a corresponding **TextUpdating** event is raised. The edit control accepts the text update. This is the state of the edit control for a brief moment before the correction is completed. The insertion point is at [4, 4].



Outside of the **TextUpdating** event handler, the edit control makes the following correction. This is the state of the edit control after the correction is complete. The insertion point is at [5, 5].



When this happens, you should call **NotifyTextChanged** with these arguments:

- *modifiedRange* = [1, 2]
- *newLength* = 2
- *newSelection* = [5, 5]

One or more **TextRequested** events will follow, which you handle to update the text that the text services are working with.

Providing requested text

It's important for text services to have the correct text to provide features like auto-correction or prediction, especially for text that already existed in the edit control, from loading a document, for example, or text that is inserted by the edit control as explained in previous sections. Therefore, whenever a **TextRequested** event is raised, you must provide the text currently in your edit control for the specified range.

There will be times the **Range** in **CoreTextTextRequest** specifies a range that your edit control cannot accommodate as-is. For example, the **Range** is larger than the size of the edit control at the time of the **TextRequested** event, or the end of the **Range** is out of bounds. In these cases, you should return whatever range makes sense, which is typically a subset of the requested range.

Text scaling

Article • 05/13/2022

Example of text scaling in Windows 11 (100% to 225%)

Overview

Reading text on a computer screen (from mobile device to laptop to desktop monitor to the giant screen of a Surface Hub) can be challenging for many people. Conversely, some users find the font sizes used in apps and web sites to be larger than necessary.

To ensure text is as legible as possible for the broadest range of users, Windows provides the ability for users to change relative font size across both the OS and individual applications. Instead of using a magnifier app (which typically just enlarges everything within an area of the screen and introduces its own usability issues), changing display resolution, or relying on DPI scaling (which resizes everything based on display and typical viewing distance), a user can quickly access a setting to resize just text, ranging from 100% (the default size) up to 225%.

Support

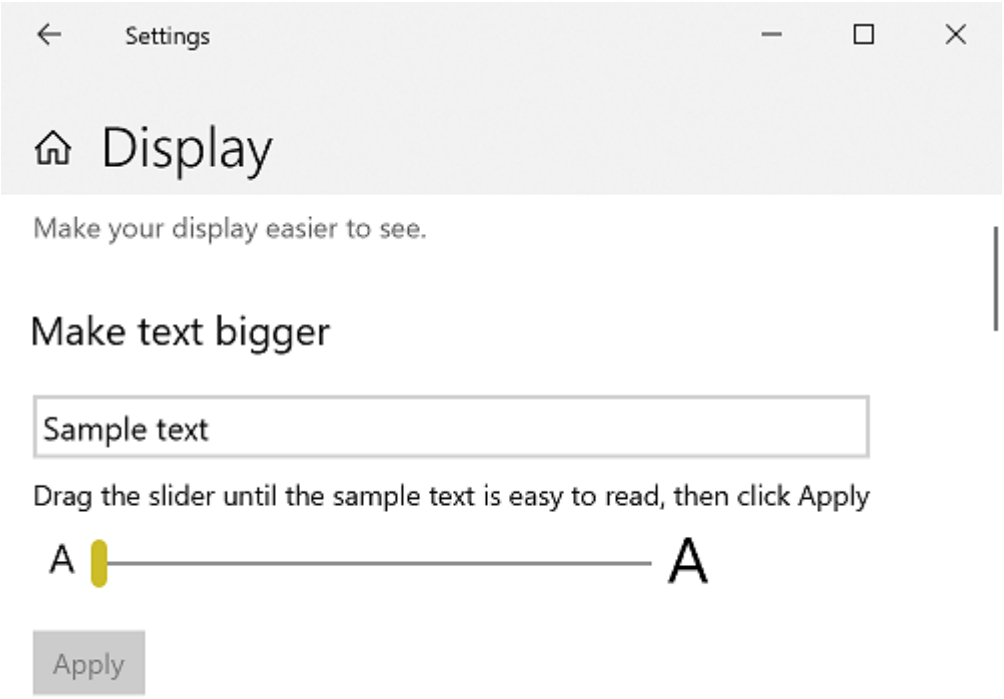
Universal Windows applications (both standard and PWA), support text scaling by default.

If your Windows application includes custom controls, custom text surfaces, hard-coded control heights, older frameworks, or 3rd party frameworks, you likely have to make some updates to ensure a consistent and useful experience for your users.

DirectWrite, GDI, and XAML SwapChainPanels do not natively support text scaling, while Win32 support is limited to menus, icons, and toolbars.

User experience

Users can adjust text scale with the Make text bigger slider on the Settings -> Ease of Access -> Vision/Display screen.



Text scale setting from Settings -> Ease of Access -> Vision/Display screen

UX guidance

As text is resized, controls and containers must also resize and reflow to accommodate the text and its new layout. As mentioned previously, depending on the app, framework, and platform, much of this work is done for you. The following UX guidance covers those cases where it's not.

Use the platform controls

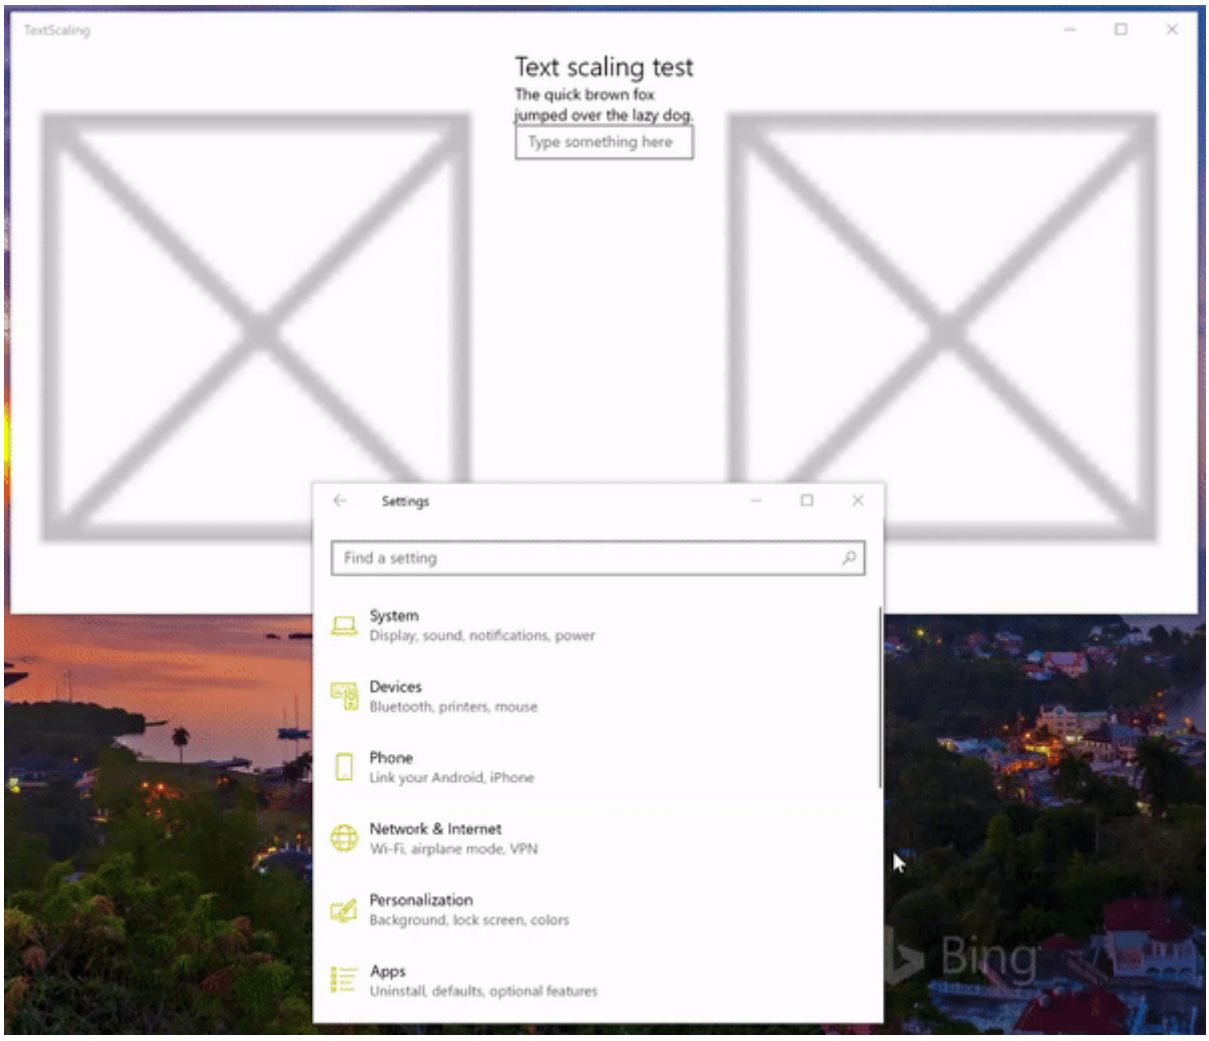
Did we say this already? It's worth repeating: When possible, always use the built-in controls provided with the various Windows app frameworks to get the most comprehensive user experience possible for the least amount of effort.

For example, all UWP text controls support the full text scaling experience without any customization or templating.

Here's a snippet from a basic UWP app that includes a couple of standard text controls:

XAML

```
<Grid>
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="Auto" />
        <RowDefinition Height="Auto"/>
    </Grid.RowDefinitions>
    <TextBlock Grid.Row="0"
               Style="{ThemeResource TitleTextBlockStyle}"
               Text="Text scaling test"
               HorizontalTextAlignment="Center" />
    <Grid Grid.Row="1">
        <Grid.ColumnDefinitions>
            <ColumnDefinition Width="Auto"/>
            <ColumnDefinition Width="*"/>
            <ColumnDefinition Width="Auto"/>
        </Grid.ColumnDefinitions>
        <Image Grid.Column="0"
               Source="Assets/StoreLogo.png"
               Width="450" Height="450"/>
        <StackPanel Grid.Column="1"
                    HorizontalAlignment="Center">
            <TextBlock TextWrapping="WrapWholeWords">
                The quick brown fox jumped over the lazy dog.
            </TextBlock>
            <TextBox PlaceholderText="Type something here" />
        </StackPanel>
        <Image Grid.Column="2"
               Source="Assets/StoreLogo.png"
               Width="450" Height="450"/>
    </Grid>
    <TextBlock Grid.Row="2"
               Style="{ThemeResource TitleTextBlockStyle}"
               Text="Text scaling test footer"
               HorizontalTextAlignment="Center" />
</Grid>
```



Animated text scaling

Use auto-sizing

Don't specify absolute sizes for your controls. Whenever possible, let the platform resize your controls automatically based on user and device settings.

In this snippet from the previous example, we use the `Auto` and `*` width values for a set of grid columns and let the platform adjust the app layout based on the size of the elements contained within the grid.

XAML

```
<Grid.ColumnDefinitions>
    <ColumnDefinition Width="Auto"/>
    <ColumnDefinition Width="*"/>
    <ColumnDefinition Width="Auto"/>
</Grid.ColumnDefinitions>
```

Use text wrapping

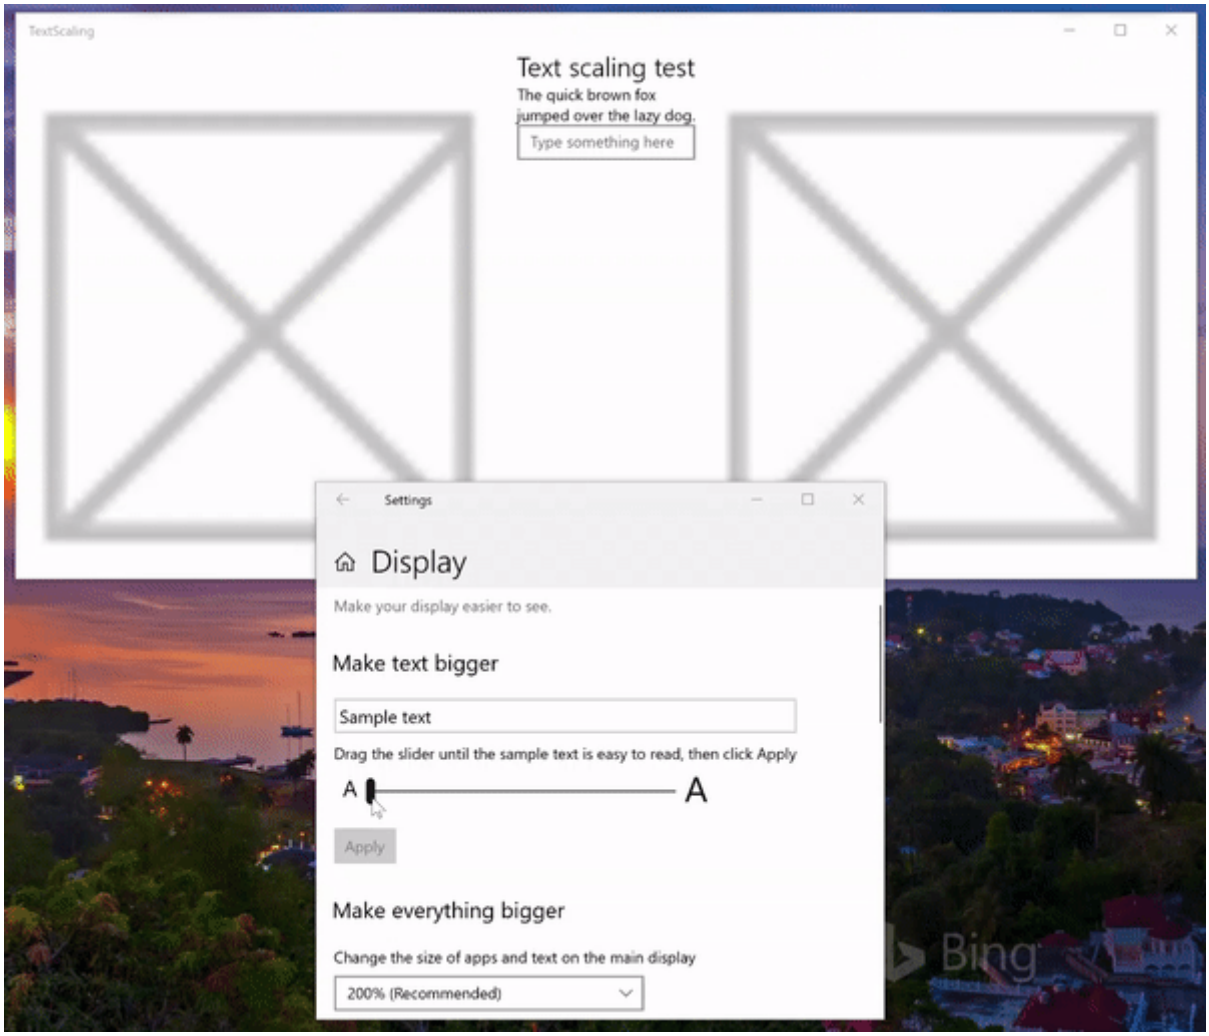
To ensure the layout of your app is as flexible and adaptable as possible, enable text wrapping in any control that contains text (many controls do not support text wrapping by default).

If you don't specify text wrapping, the platform uses other methods to adjust the layout, including clipping (see previous example).

Here, we use the `AcceptsReturn` and `TextWrapping` TextBox properties to ensure our layout is as flexible as possible.

XAML

```
<TextBox PlaceholderText="Type something here"
         AcceptsReturn="True" TextWrapping="Wrap" />
```



Animated text scaling with text wrapping

Specify text trimming behavior

If text wrapping is not the preferred behavior, most text controls let you either clip your text or specify ellipses for the text trimming behavior. Clipping is preferred to ellipses as

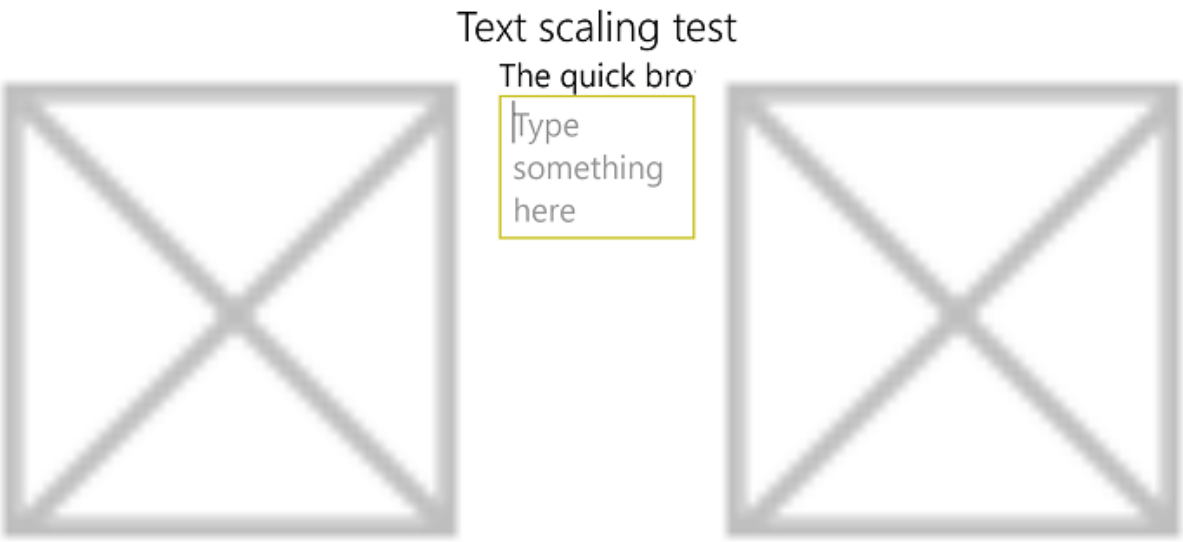
ellipses take up space themselves.

> **Note**
>
> If you need to clip your text, clip the end of the string, not the beginning.

In this example, we show how to clip text in a TextBlock using the TextTrimming property.

XAML

```
<TextBlock TextTrimming="Clip">
    The quick brown fox jumped over the lazy dog.
</TextBlock>
```



Text scaling with text clipping

Use a tooltip

If you clip text, use a tooltip to provide the full text to your users.

Here, we add a tooltip to a TextBlock that doesn't support text wrapping:

XAML

```
<TextBlock TextTrimming="Clip">
    <ToolTipService.ToolTip>
        <ToolTip Content="The quick brown fox jumped over the lazy dog."/>
    </ToolTipService.ToolTip>
    The quick brown fox jumped over the lazy dog.
</TextBlock>
```

Don’t scale font-based icons or symbols

When using font-based icons for emphasis or decoration, disable scaling on these characters.

Set the IsTextScaleFactorEnabled property to `false` for most XAML controls.

Support text scaling natively

Handle the TextScaleFactorChanged UISettings system event in your custom framework and controls. This event is raised each time the user sets the text scaling factor on their system.

Summary

This topic provides an overview of text scaling support in Windows and includes UX and developer guidance on how to customize the user experience.

Selecting text and images

Article • 06/24/2021

This article describes selecting and manipulating text, images, and controls and provides user experience guidelines that should be considered when using these mechanisms in your apps.

> **Important APIs**: Windows.UI.Xaml.Input, Windows.UI.Input

Dos and don'ts

- Use font glyphs when implementing your own gripper UI. The gripper is a combination of two Segoe UI fonts that are available system-wide. Using font resources simplifies rendering issues at different dpi and works well with the various UI scaling plateaus. When implementing your own grippers, they should share the following UI traits:
  - Circular shape
  - Visible against any background
  - Consistent size

- Provide a margin around the selectable content to accommodate the gripper UI. If your app enables text selection in a region that doesn't pan/scroll, allow a 1/2 gripper margin on the left and right sides of the text area and 1 gripper height on the top and bottom sides of the text area (as shown in the following images). This ensures that the entire gripper UI is exposed to the user and minimizes unintended interactions with other edge-based UI.

- Hide grippers UI during interaction. Eliminates occlusion by the grippers during the interaction. This is useful when a gripper isn't completely obscured by the finger or there are multiple text selection grippers. This eliminates visual artifacts when displaying child windows.

- Don't allow selection of UI elements such as controls, labels, images, proprietary content, and so on. Typically, Windows applications allow selection only within specific controls. Controls such as buttons, labels, and logos are not selectable. Assess whether selection is an issue for your app and, if so, identify the areas of the UI where selection should be prohibited.

Additional usage guidance

Text selection and manipulation is particularly susceptible to user experience challenges introduced by touch interactions. Mouse, pen/stylus, and keyboard input are highly granular: a mouse click or pen/stylus contact is typically mapped to a single pixel, and a key is pressed or not pressed. Touch input is not granular; it's difficult to map the entire surface of a fingertip to a specific x-y location on the screen to place a text caret accurately.

Considerations and recommendations

Use the built-in controls exposed through the language frameworks in Windows to build apps that provide the full platform user interaction experience, including selection and manipulation behaviors. You'll find the interaction functionality of the built-in controls sufficient for the majority of Windows apps.

When using standard Windows text controls, the selection behaviors and visuals described in this topic cannot be customized.

Text selection

If your app requires a custom UI that supports text selection, we recommend that you follow the Windows selection behaviors described here.

Editable and non-editable content

With touch, selection interactions are performed primarily through gestures such as a tap to set an insertion cursor or select a word, and a slide to modify a selection. As with other Windows touch interactions, timed interactions are limited to the press and hold gesture to display informational UI. For more information, see Guidelines for visual feedback.

Windows recognizes two possible states for selection interactions, editable and non-editable, and adjusts selection UI, feedback, and functionality accordingly.

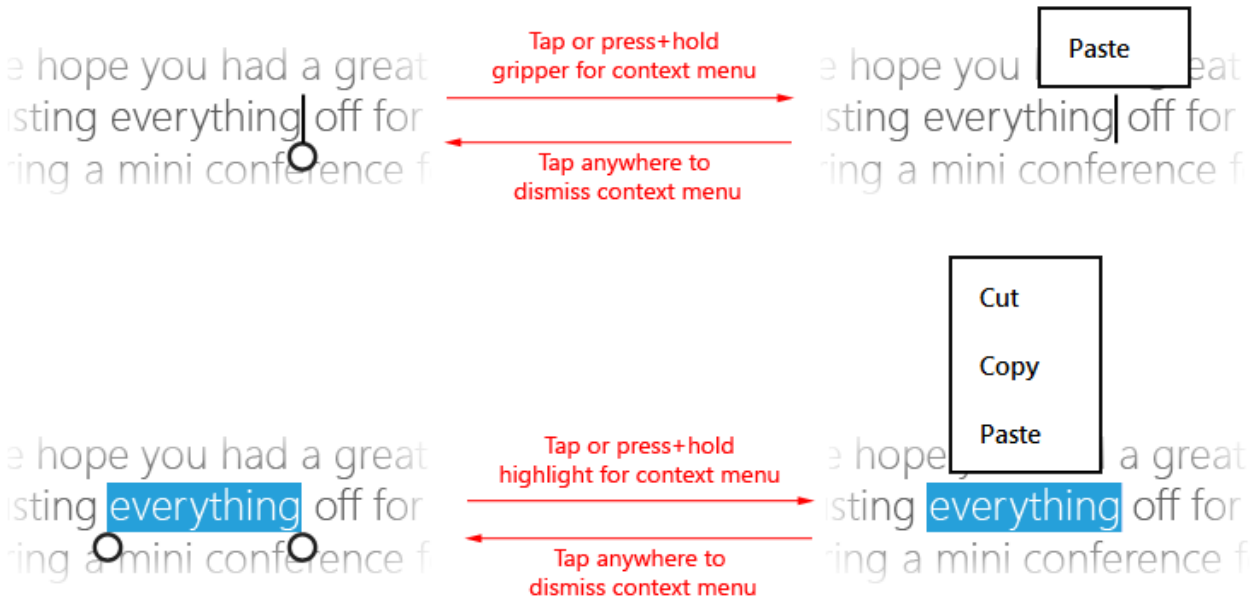
Editable content

Tapping within the left half of a word places the cursor to the immediate left of the word, while tapping within the right half places the cursor to the immediate right of the word.

The following image demonstrates how to place an initial insertion cursor with gripper by tapping near the beginning or ending of a word.

The following image demonstrates how to adjust a selection by dragging the gripper.

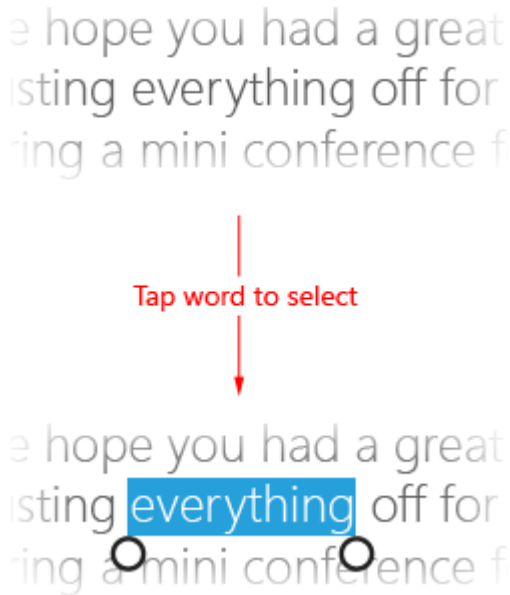
The following images demonstrate how to invoke the context menu by tapping within the selection or on a gripper (press and hold can also be used).



Note These interactions vary somewhat in the case of a misspelled word. Tapping a word that is marked as misspelled will both highlight the entire word and invoke the suggested spelling context menu.

Non-editable content

The following image demonstrates how to select a word by tapping within the word (no spaces are included in the initial selection).

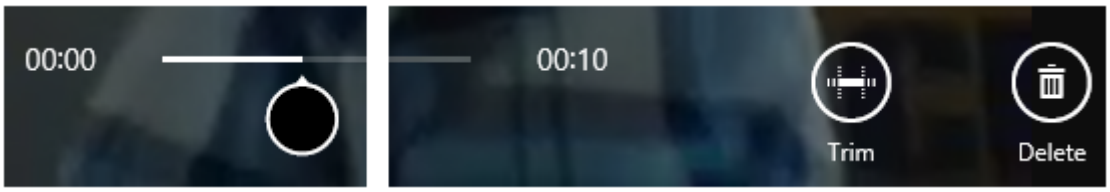


Follow the same procedures as for editable text to adjust the selection and display the context menu.

Object manipulation

Wherever possible, use the same (or similar) gripper resources as text selection when implementing custom object manipulation in a Windows app. This helps provide a consistent interaction experience across the platform.

For example, grippers can also be used in image processing apps that support resizing and cropping or media player apps that provide adjustable progress bars, as shown in the following images.



Media player with adjustable progress bar.

Image editor with cropping grippers.

Input Method Editors (IME)

Article • 06/24/2021

An Input Method Editor (IME) is a software component that enables a user to input text in a language that can't be represented easily on a standard QWERTY keyboard. This is typically due to the number of characters in the user's written language, such as the various East Asian languages.

Instead of each single character appearing on a single keyboard key, a user types combinations of keys that are interpreted by the IME. The IME generates either the character that matches the set of key strokes or a list of candidate characters to choose from. The selected character is then inserted into the edit control that the user is interacting with.

> **Note**
>
> IMEs can support both hardware keyboards and on-screen or touch keyboards.

Your app doesn't need to interact directly with the IME. The IME is built into the system, just as the touch keyboard is. If your app has text input, and you intend to support text input in languages that require an IME, you should test the end-to-end customer experience for text entry. This lets you fix any issues, such as adjusting your UI so it isn't occluded by the touch keyboard or IME candidate window.

Creating an IME

To enable a great input experience for all users, Microsoft produces IMEs that ship in-box for a variety of languages.

In addition to the in-box IMEs, you can build your own custom IMEs that users can install and use just like an in-box IME.

All IMEs run in the Windows system, which is hardened to stop malicious IMEs and to improve the security and user experience of all IMEs.

Custom IMEs can link to the default touch keyboard and use its layout so that end users can use their IME with the touch keyboard. However, you cannot provide your own independent touch keyboard and certain functions of in-box IMEs for touch keyboards are not available to custom IMEs.

Requirements for IMEs

A third-party IME must meet these requirements:

- Must be digitally signed
- Must be Text Services Framework (TSF) aware, with appropriate IME flags set correctly
- Must follow the guidelines described in Input Method Editor (IME) requirements and Design and code Windows apps

A third-party IME that doesn't meet these requirements is blocked from running.

> **Note**
>
> Legacy custom IMEs can run in desktop apps, but are blocked in Windows apps.

Also, Windows Defender removes malicious IMEs from the system. Because of this, it's important that you familiarize yourself with the IME coding requirements. For more info, see Input Method Editor (IME) requirements.

Design guidelines for IMEs

Read the Input Method Editor (IME) requirements for more details on best practices and design guidelines for IMEs. In general, all IME UIs need to:

- Follow the UX guidelines for Windows Runtime apps
- Avoid modal experiences and only show the IME window when needed
- include icons that are black and white only

Custom Input Method Editor (IME) requirements

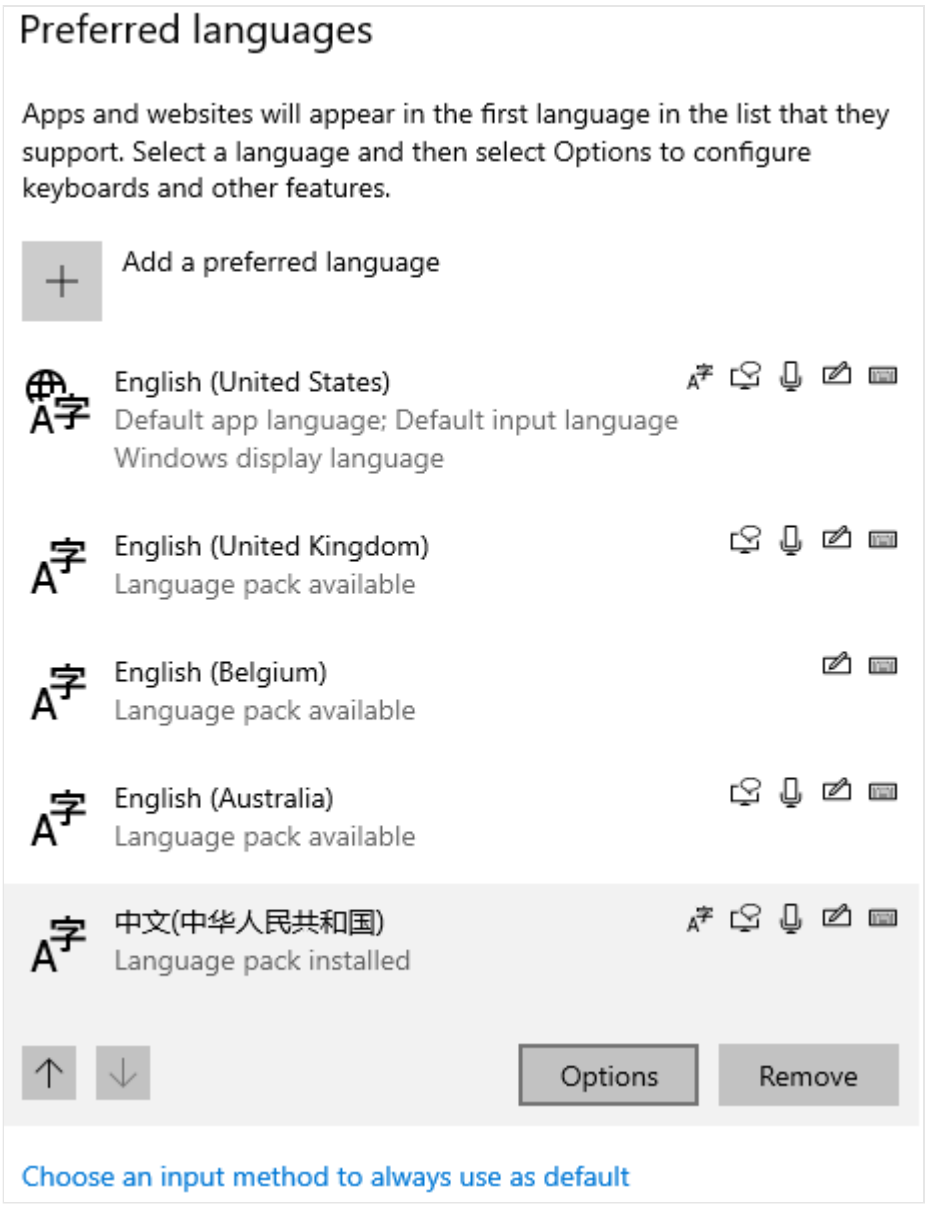
Article • 06/24/2021

These guidelines and requirements can help you to develop a custom Input Method Editor (IME) to help a user input text in a language that can't be represented easily on a standard QWERTY keyboard.

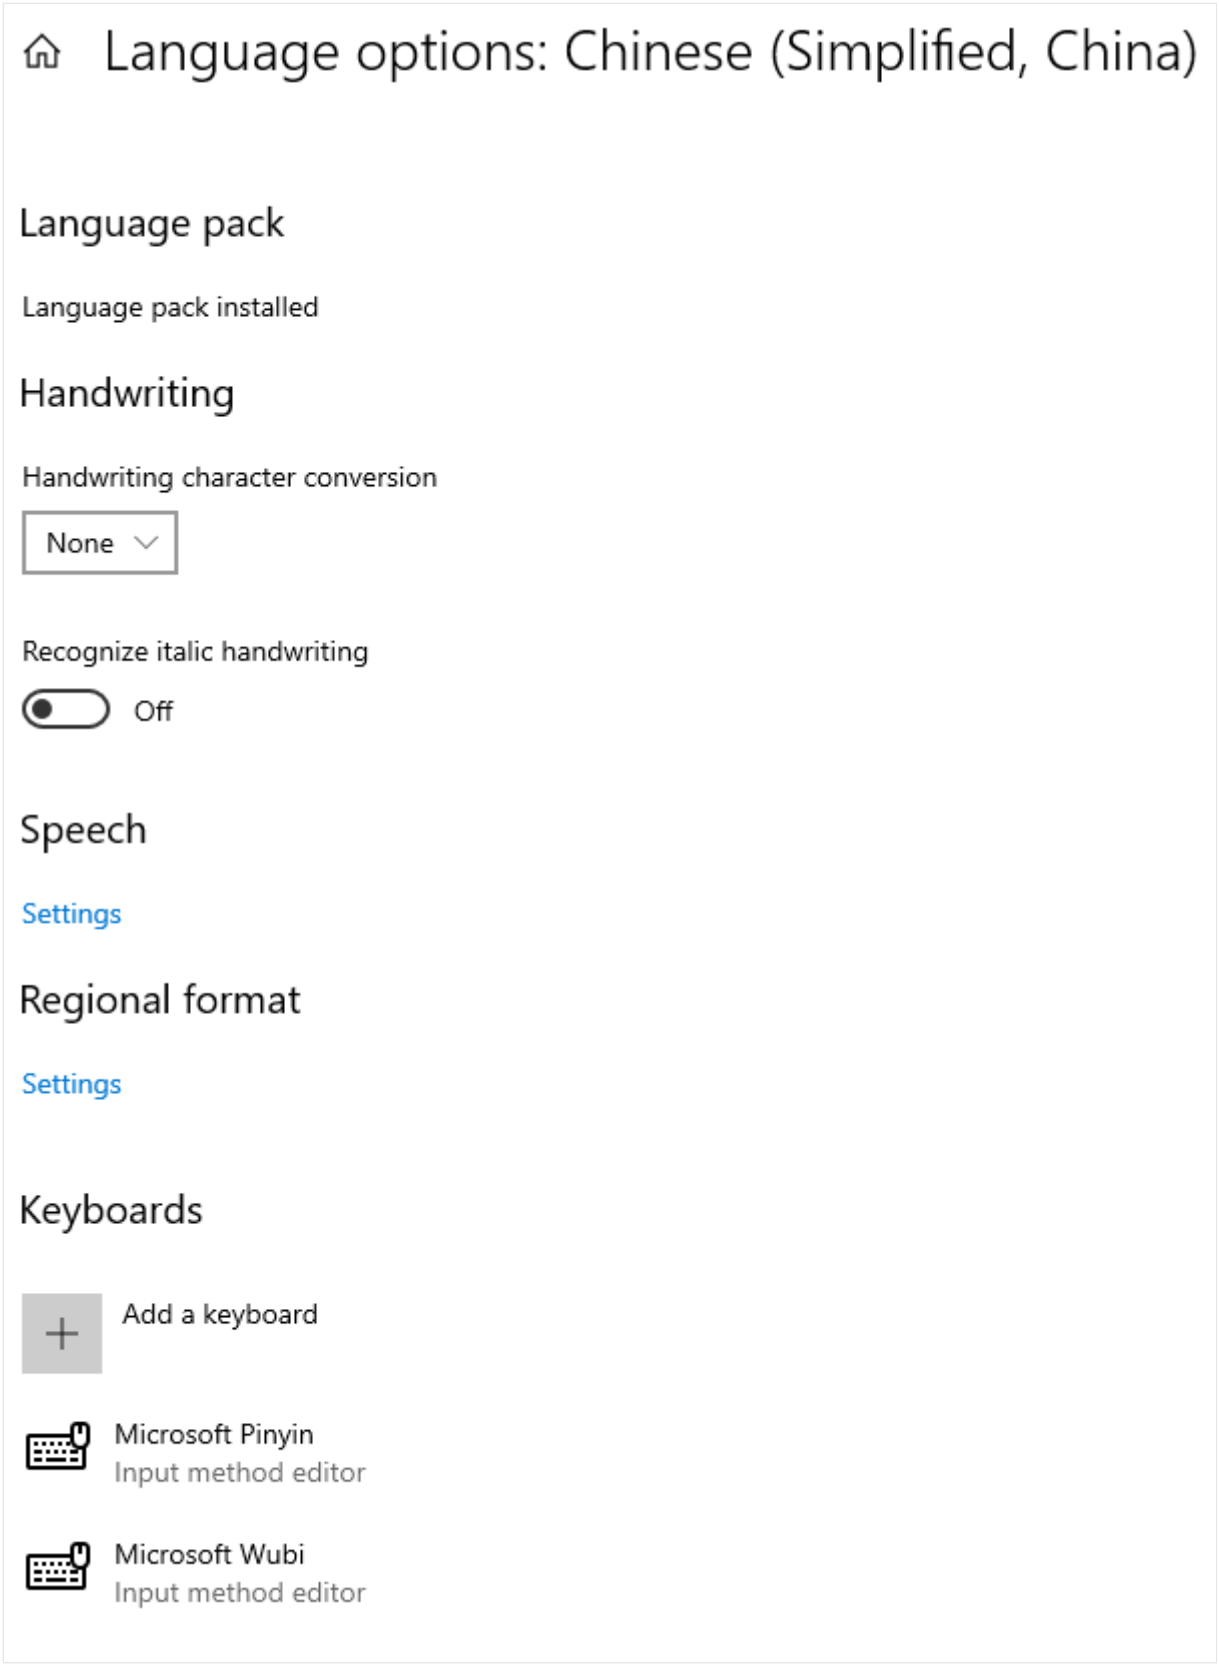
For an overview of IMEs, see Input Method Editor (IME).

Default IME

A user can select any of their active IMEs (**Settings -> Time & Language -> Language -> Preferred languages -> Language pack - Options**) to be the default IME for their preferred language.



Select the default keyboard on the Language options settings screen for the preferred language.



ⓘ Important

We do not recommend writing directly to the registry to set the default keyboard for your custom IME.

Compatibility requirements

The following are the basic compatibility requirements for a custom IME.

IME must be compatible with Windows apps

Use the Text Services Framework (TSF) to implement IMEs. Previously, you had the option of using the Input Method Manager (IMM32) for input services. Now the system blocks IMEs that are implemented by using Input Method Manager (IMM32).

When an app starts, TSF loads the IME DLL for the IME that's currently selected by the user. When an IME is loaded, it's subject to the same app container restrictions as the app. For example, an IME can't access the Internet if an app hasn't requested Internet access in its manifest. This behavior ensures that IMEs can't violate security contracts.

TSF is the intermediary between the app and your IME. TSF communicates input events to the IME and receives input characters back from the IME after the user has selected a character.

This behavior is the same as previous versions of Windows, but being loaded into a Windows app affects the potential capabilities of an IME.

If your IME needs to provide different functionality or UI between Windows apps and desktop apps, ensure that the DLL that's loaded by TSF checks which type of app it's being loaded into. Call the ITfThreadMgrEx::GetActiveFlags method in your IME and check the TF_TMF_IMMERSIVEMODE flag, so your IME triggers different application logic depending on the result.

Windows apps do not support Table Text Service (TTS) IMEs.

> **Note**
>
> Some tools for generating TTS IMEs produce IMEs that are marked as malware by Windows.

IME must be compatible with the system tray

There is no language bar to host IME icons. Instead, an Input Indicator shows on the system tray that indicates the current input option. The Input Indicator shows only the IME branding icon to indicate the currently running IME. Also, there's one IME mode icon that shows on the left of the IME branding icon for users to perform the most commonly used IME mode switch, like turning the IME on or off.

The Input Indicator shows the IME branding icon and mode icon only for compatible IMEs. IMEs that aren't compatible don't have the branding icon and mode icon displayed in the system tray. Instead, the Input Indicator shows the language abbreviation instead of the IME branding icon.

Store the IME icons in a DLL or EXE file, instead of a standalone .ico file. The design of IME icons must follow the guidelines described in the following UI design guidelines section.

IME branding icon

The Input Indicator gets the IME branding icon from the IME DLL by using the resource ID defined by the IME when it was registered on the system.

IME mode icon

Some IMEs may need to rely on the Input Indicator showing on the system tray to display the IME mode icon. In this case, the IME passes the IME mode icon to the Input Indicator by using GUID_LBI_INPUTMODE.

When passing the IME mode icons to the Input Indicator on the system tray, the default size of the IME mode icon is 16x16 pixels. The UI scaling follows DPI.

When passing the IME mode icon to the Input Indicator on UAC (User Account Control in Secure Desktop), the default size of the IME mode icon is 20x20 pixels. The UI scaling for IME mode icon on UAC follows PPI.

IME must work in app container

Some IME functions are affected in an app container.

- **Dictionary Files** - Frequently, IMEs have read-only dictionary files to map user input to specific characters. To access these files from inside an app container, your IME must place them under the Program Files or Windows directories. By default, these directories can be read from an app container, so IMEs can access dictionary files that are stored in these locations. If your IME must store the dictionary file somewhere else, it must explicitly manipulate the Access Control Lists (ACL) of the dictionary files to allow access from app containers.
- **Internet Updating** - If your IME needs to update its dictionaries using data from the Internet, it can't reliably do so inside an app container, because Internet access

isn't always permitted. Instead, your IME should run a separate desktop process that's responsible for updating the dictionary files with data from the Internet.

- **On-the-fly learning** - If an IME is running in an app container that has Internet access, there's no restriction on the endpoints that the IME can communicate with. In this case, an IME can use a cloud server to provide on-the-fly learning services. Some IMEs download and upload user input on the fly, while the user is typing. Since Internet access is not guaranteed in an app container, this may not always be allowed.
- **Sharing information between processes** - IMEs may need to share data about the user's input preferences between apps that are in different app containers. Use a web service to share data between apps.

> **Important**
>
> If you try to circumvent app container security rules, your IME may be treated as malware and blocked.

IME and touch keyboard

Your IME must ensure that its candidate pane's UI, and other UI elements, aren't drawn underneath the touch keyboard. The touch keyboard is displayed in a higher z-order band than all apps, and the IME UI is displayed in the same z-order band as the app it's active in. As a result, the touch keyboard can overlap and hide the IME UI. In most cases, the app should resize its window to account for the touch keyboard. If an app doesn't resize, the IME still can use the InputPane API to get the position of the touch keyboard. The IME queries the Location property, or it registers a handler for the touch keyboard's Show and Hide events. The Show event is raised every time the user taps in an edit field, even if the touch keyboard is displayed currently. Your IME can use this API to get the screen space used by the touch keyboard before the IME draws candidate (or other) UI, and to reflow the IMEs UI to avoid drawing beneath the touch keyboard.

Specifying the preferred touch keyboard layout

The IME can specify which touch keyboard layout to use, and the IME is enabled to work with touch-optimized layouts. This functionality is limited to IMEs for the Korean, Japanese, Chinese Simplified, and Chinese Traditional input languages.

There are seven layouts supported by the touch keyboard, three of which are classic layouts and four of which are touch-optimized layouts. The classic layouts look and behave like a physical keyboard.

All of the three classic layouts are for inputting traditional Chinese in different forms:

- Phonetic-based input
- Changjie input
- Dayi input

In addition to the classic layouts, there is one touch-optimized layout for each of the Korean, Japanese, Simplified Chinese, and Traditional Chinese input languages.

To use this functionality, your IME must implement the ITfFnGetPreferredTouchKeyboardLayout interface, which is exported by the IME by using the Text Services Framework ITfFunctionProvider API.

If your IME doesn't support the ITfFnGetPreferredTouchKeyboardLayout interface, using the IME results in the default classic layout for the language that is displayed by the touch keyboard.

If your IME needs to set one of the classic layouts as the preferred layout, no additional work is required on the IME side beyond supporting the ITfFnGetPreferredTouchKeyboardLayout and ITfFunctionProvider interfaces. But additional work is required in the IME to work with the touch-optimized layouts, and this is described in the next section.

Touch-optimized layout

The touch-optimized keyboards for the Korean, Japanese, Simplified Chinese, and Traditional Chinese input languages display a different layout for IME On and IME Off conversion modes. There's a key on the touch keyboard to set the IME conversion mode to On or Off, but the IME mode of the keyboard also may change as focus changes among edit controls.

The touch-optimized keyboards for the Japanese, Simplified Chinese, and Traditional Chinese input languages contain a key, or keys, which the IME uses to navigate through candidate pages. For Japanese and Simplified Chinese, the candidate page key displays on the touch-optimized layout. For Traditional Chinese, there are separate keys for the previous and next candidate pages.

When these keys are pressed, the touch keyboard calls the SendInput function to send the following Unicode Private Use Area characters to the focused application, which the IME can intercept and act on:

- **Next page (0xF003)** - Sent when the candidate page key is pressed on the touch-optimized keyboard for Japanese and Simplified Chinese, or when the next page

key is pressed on the touch-optimized keyboard for Traditional Chinese.

- **Previous page (0xF004)** - Sent when either the candidate page key is pressed at the same time as the Shift key on the touch-optimized keyboard for Japanese and Simplified Chinese, or when the previous page key is pressed on the touch-optimized keyboard for Traditional Chinese.

These characters are sent as Unicode input. The next paragraph details how to extract the character information during the key event sink notifications that the Text Services Framework IME will receive. These character values are not defined in any header file, so you will need to define them in your code.

To intercept keyboard input, your IME must register as a key event sink. For Unicode input that is generated by using the SendInput function, the WPARAM parameter of the ITfKeyEventSink callbacks (OnKeyDown, OnKeyUp, OnTestKeyDown, OnTestKeyUp) always contains the virtual key VK_PACKET and doesn't identify the character directly.

Implement the following call sequence to access the character:

```
C++

// Keyboard state
BYTE abKbdState[256];
if (!GetKeyboardState(abKbdState))
{
   return 0;
}

// Map virtual key to character code
WCHAR wch;
if (ToUnicode(VK_PACKET, 0, abKbdState, &wch, 1, 0) == 1)
{
   return wch;
}
```

IME search integration

Provide users with search features through the search contract and integration with the search pane.

Search pane and IME suggestions

The search pane is a central location for users to perform searches across all of their apps. For IME users, Windows provides a unique search experience that lets compatible IMEs integrate with Windows for greater efficiency and usability.

Users who type with an IME that's compatible with search get two main benefits:

- Seamless interaction between the IME and the search experience. IME candidates are shown inline under the search box without occluding search suggestions. The user can use the keyboard to navigate seamlessly between the search box, the IME conversion candidates, and the search suggestions.
- Faster access to relevant results and suggestions provided by applications. The app has access to all current conversion candidates to provide more relevant suggestions. To better prioritize search suggestions, conversions are given to apps in order of relevance. Users find and select the result they want without converting, just by typing in phonetic.

An IME is compatible with the integrated search experience if it meets the following criteria:

- Compatible with the Windows style shell.
- Implement the TSF UILess mode APIs. For more info, see UILess Mode Overview.
- Implement the TSF search integration APIs, ITfFnSearchCandidateProvider and ITfIntegratableCandidateListUIElement.

When activated in the search pane, a compatible IME is placed in UIless mode and can't show its UI. Instead, it sends conversion candidates to Windows, which displays them in the inline candidate list control, as shown in the previous screenshot.

Also, the IME sends candidates that should be used to run the current search. These candidates could be the same as the conversion candidates, or they could be tailored for search.

Good search candidates meet the following criteria:

- No prefix overlap. For example, 北京大学 and北京 are redundant because one is a prefix of the other.
- No redundant candidates. Any redundant candidate isn't useful for search because it doesn't help filter results. For example, any result that matches 北京大学 also matches 北京.
- No prediction candidate, only conversion. For example, if the user types "be", the IME can return 北 as a candidate, but not 北京大学. Usually, prediction candidates are too restrictive.

IMEs that don't meet the criteria aren't compatible with search display in the same way as other controls, and can't take advantage of UI integration and search candidates. Apps receive queries only after the user has finished composing.

When an app that supports the search contract receives a query, the query event contains a "queryTextAlternatives" array that contains all known alternatives, ranked from the most relevant (likely) to least relevant (unlikely).

When alternatives are provided, the app should treat each alternative as a query and return all results that match any of the alternatives. The app should behave as if the user had issued multiple queries at the same time, essentially issuing an "or" query to the service providing the results. For performance considerations, apps often limit matching to between 5 and 20 of the most relevant alternatives.

UI design guidelines

All IMEs must follow the user experience guidelines described in Design and code Windows apps.

Don't use sticky windows

Your IME windows should appear only when needed, and they shouldn't be visible all the time. When users don't need to type, IME windows shouldn't show. The IME window shouldn't be a full screen window. IME windows shouldn't overlap each other. The windows should be designed in a Windows style and follow UI scaling.

IME icons

There are two kinds of IME icons, branding icons and mode icons. All IME icons must be designed with black and white colors only. The new IME icons borrow from the glyphic look of the system tray icons. This style has been created so all languages can use it to complement the familial look while also differentiating from each other.

The file format for IME icons is ICO. You must provide the following icon sizes.

- 16x16 pixels
- 20x20 pixels
- 24x24 pixels
- 32x32 pixels
- 40x40 pixels
- 48x48 pixels

Ensure that 32-bit icons with alpha channel are provided in all resolutions.

IME brand icons are defined by a white box in which a typographic glyph rendered in a modern typeface is placed. Each defining glyph is chosen by each language team. The glyph is black. The box includes an outer stroke of 1 pixel in black at 50% opacity. "New" versions are defined by a rounded corner in the upper left of the box.

IME mode icons are defined by a white typographic glyph in a modern typeface which includes an outer stroke of 1 pixel in black at 50% opacity.

Icon	Description
	Example IME brand icon for Traditional Chinese ChangeJie.
	Example IME brand icon for Traditional Chinese ChangeJie.

Icon	Description
	Example IME mode icon.

Owned window

To display candidate UI, an IME must set its window to be owned-window, so it can display over the currently running app. Use the ITfContextView::GetWnd method to retrieve the window to own to. If GetWnd returns an error or a NULLHWND, call the GetFocus function.

```
if (FAILED(pView->GetWnd(&parentWndHandle)) || (parentWndHandle == nullptr)) { parentWndHandle = GetFocus(); }
```

IME candidate window interaction with light dismiss surfaces

The dismissal model for popup windows is called "light dismiss" because it's easy for a user to close such windows. For IMEs to function well in the Windows interaction model, the IME windows must participate in the light dismiss model.

In order to participate in the light dismiss model, your IME must raise three new Windows events by using the NotifyWinEvent function or a similar function. These new events are:

- **EVENT_OBJECT_IME_SHOW** - Raise this event when the IME becomes visible.
- **EVENT_OBJECT_IME_HIDE** - Raise this event when the IME is hidden.
- **EVENT_OBJECT_IME_CHANGE** - Raise this event when the IME moves or changes size.

Declaring compatibility

IMEs declare that they are compatible by registering the category GUID_TFCAT_TIPCAP_IMMERSIVESUPPORT for their IME using ITfCategoryMgr::RegisterCategory.

Set the default IME mode to on

We provide a better UX for IMEs.

DPI scaling support for desktop applications

Enhanced DPI scaling support enables querying the declared DPI awareness level of each desktop process to determine if it needs to scale the UI. In a multi-monitor scenario, Windows scales the UI appropriately for different DPI settings on each monitor.

Because your IME runs in the context of each application's process, you shouldn't declare a DPI awareness level for your IME. This ensures that your IME runs at the DPI awareness level of the current process.

To ensure that all IME UI elements have scaling parity with the UI elements of the process in which you are running, you must respond appropriately to different DPI values.

> **Note**
>
> To ensure parity with new desktop applications, your IME should support per monitor–DPI awareness, but shouldn't declare a level of awareness itself. The system determines the appropriate scaling requirements in each scenario.

For details about DPI scaling support requirements for Desktop applications, see High DPI.

IME installation

If you build your IME by using Microsoft Visual Studio, create an installation experience for your IME by using a third-party installer, like InstallShield from Flexera Software.

The following steps show how to use InstallShield to create a setup project for your IME DLL.

- Install Visual Studio.
- Start Visual Studio.
- On the **File** menu, point to **New** and select **Project**. The **New Project** dialog opens.
- In the left pane, navigate to **Templates** > **Other Project Types** > **Setup and Deployment**, click **Enable InstallShield Limited Edition**, and click **OK**. Follow the installation instructions.
- Restart Visual Studio.
- Open the IME solution (.sln) file.

- In Solution Explorer, right-click the solution, point to **Add**, and select **New Project**. The **Add New Project** dialog opens.
- In the left tree view control, navigate to **Templates** > **Other Project Types** > **InstallShield Limited Edition**.
- In the center window, click **InstallShield Limited Edition Project**.
- In the **Name** text box, type "SetupIME" and click **OK**.
- In the **Project Assistant** dialog, click **Application Information**.
- Fill in your company name and the other fields.
- Click **Application Files**.
- In the left pane, right-click the **[INSTALLDIR]** folder, and select **New Folder**. Name the folder "Plugins".
- Click **Add Files**. Navigate to your IME DLL and add it to the **Plugins** folder. Repeat this step for the IME dictionary.
- Right-click the IME DLL and select **Properties**. The **Properties** dialog opens.
- In the **Properties** dialog, click the **COM & .NET Settings** tab.
- Under **Registration Type**, select **Self-registration** and click **OK**.
- Build the solution. The IME DLL is built, and InstallShield creates a setup.exe file that enables users to install your IME on Windows.

To create your own installation experience, call the ITfInputProcessorProfileMgr::RegisterProfile method to register the IME during installation. Don't write registry entries directly.

If the IME must be usable immediately after installation, call InstallLayoutOrTip to add the IME to user-enabled input methods, using the following format for the psz parameter:

```
<LangID 1>:{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}
```

IME accessibility

Implement the following convention to make your IMEs conform to the accessibility requirements and to work with Narrator. To make candidate lists accessible, your IMEs must follow this convention.

- The candidate list must have a **UIA_AutomationIdPropertyId** equal to "IME_Candidate_Window" for lists of conversion candidates or "IME_Prediction_Window" for lists of prediction candidates.
- When the candidate list appears and disappears, it raises events of type **UIA_MenuOpenedEventId** and **UIA_MenuClosedEventId**, respectively

- When the current selected candidate changes, the candidate list raises a **UIA_SelectionItem_ElementSelectedEventId**. The selected element should have a property **UIA_SelectionItemIsSelectedPropertyId** equal to **TRUE**.
- The **UIA_NamePropertyId** for each item in the candidate list must be the name of the candidate. Optionally, you can provide additional information to disambiguate candidates through **UIA_HelpTextPropertyId**.

Gamepad and remote control interactions

Article • 05/13/2022

Many interaction experiences are shared between gamepad, remote control, and keyboard

Build interaction experiences in your Windows applications that ensure your app is usable and accessible through both the traditional input types of PCs, laptops, and tablets (mouse, keyboard, touch, and so on), as well as the input types typical of the TV and Xbox *10-foot* experience, such as the gamepad and remote control.

See Designing for Xbox and TV for general design guidance on Windows applications in the *10-foot* experience.

Overview

In this topic, we discuss what you should consider in your interaction design (or what you don't, if the platform looks after it for you), and provide guidance, recommendations, and suggestions for building Windows applications that are enjoyable to use regardless of device, input type, or user abilities and preferences.

Bottom line, your application should be as intuitive and easy to use in the *2-foot* environment as it is in the *10-foot* environment (and vice versa). Support the user's preferred devices, make the UI focus clear and unmistakable, arrange content so navigation is consistent and predictable, and give users the shortest path possible to what they want to do.

> **Note**
>
> Most of the code snippets in this topic are in XAML/C#; however, the principles and concepts apply to all Windows apps. If you're developing an HTML/JavaScript Windows app for Xbox, check out the excellent TVHelpers library on GitHub.

Optimize for both 2-foot and 10-foot experiences

At a minimum, we recommend that you test your applications to ensure they work well in both 2-foot and 10-foot scenarios, and that all functionality is discoverable and accessible to the Xbox gamepad and remote-control.

Here are some other ways you can optimize your app for use in both 2-foot and 10-foot experiences and with all input devices (each links to the appropriate section in this topic).

> **Note**
>
> Because Xbox gamepads and remote controls support many Windows keyboard behaviors and experiences, these recommendations are appropriate for both input types. See Keyboard interactions for more detailed keyboard info.

Expand table

Feature	Description
XY focus navigation and interaction	**XY focus navigation** enables the user to navigate around your app's UI. However, this limits the user to navigating up, down, left, and right. Recommendations for dealing with this and other considerations are outlined in this section.
Mouse mode	XY focus navigation isn't practical, or even possible, for some types of applications, such as maps or drawing and painting apps. In these cases,

Feature	Description
	mouse mode lets users navigate freely with a gamepad or remote control, just like a mouse on a PC.
Focus visual	The focus visual is a border that highlights the currently focused UI element. This helps the user quickly identify the UI they are navigating through or interacting with.
Focus engagement	Focus engagement requires the user to press the **A/Select** button on a gamepad or remote control when a UI element has focus in order to interact with it.
Hardware buttons	The gamepad and remote control provide very different buttons and configurations.

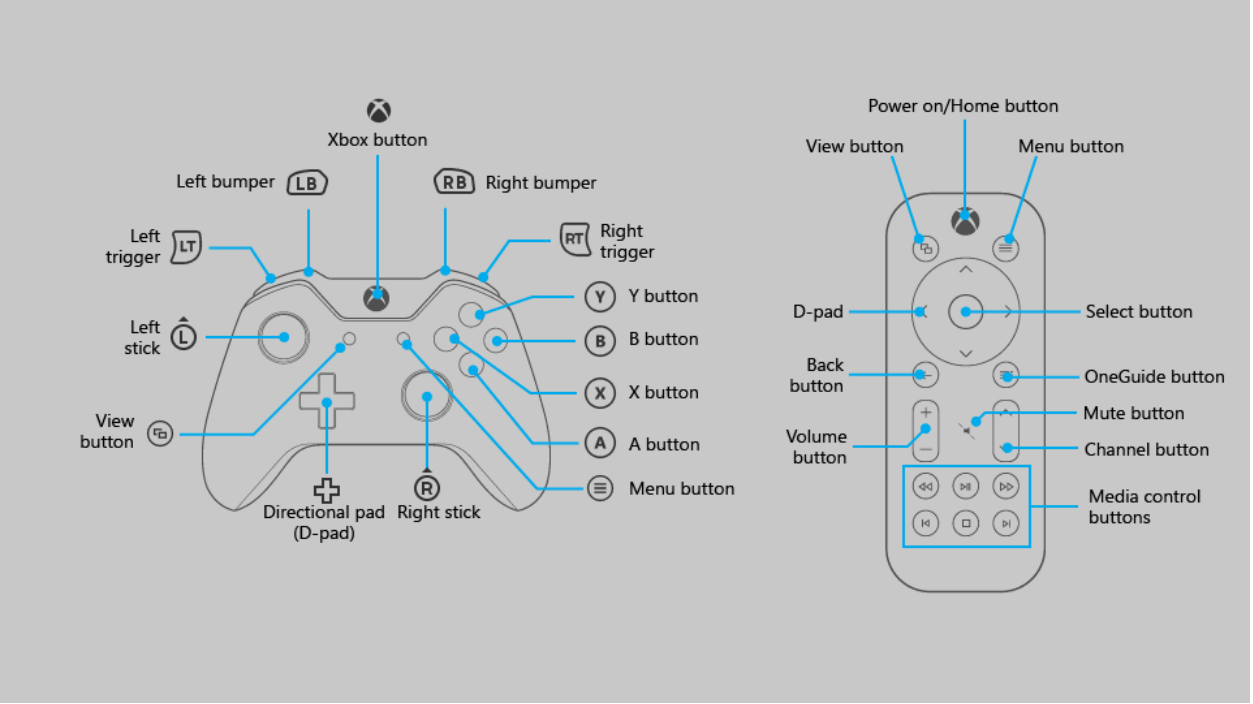
Gamepad and remote control

Just like keyboard and mouse are for PC, and touch is for phone and tablet, gamepad and remote control are the main input devices for the 10-foot experience. This section introduces what the hardware buttons are and what they do. In XY focus navigation and interaction and Mouse mode, you will learn how to optimize your app when using these input devices.

The quality of gamepad and remote behavior that you get out-of-the-box depends on how well keyboard is supported in your app. A good way to ensure that your app will work well with gamepad/remote is to make sure that it works well with keyboard on PC, and then test with gamepad/remote to find weak spots in your UI.

Hardware buttons

Throughout this document, buttons will be referred to by the names given in the following diagram.



As you can see from the diagram, there are some buttons that are supported on gamepad that are not supported on remote control, and vice versa. While you can use buttons that are only supported on one input device to make navigating the UI faster, be aware that using them for critical interactions may create a situation where the user is unable to interact with certain parts of the UI.

The following table lists all of the hardware buttons supported by Windows apps, and which input device supports them.

Expand table

Button	Gamepad	Remote control
A/Select button	Yes	Yes
B/Back button	Yes	Yes
Directional pad (D-pad)	Yes	Yes
Menu button	Yes	Yes
View button	Yes	Yes
X and Y buttons	Yes	No
Left stick	Yes	No
Right stick	Yes	No
Left and right triggers	Yes	No

Button	Gamepad	Remote control
Left and right bumpers	Yes	No
OneGuide button	No	Yes
Volume button	No	Yes
Channel button	No	Yes
Media control buttons	No	Yes
Mute button	No	Yes

Built-in button support

UWP automatically maps existing keyboard input behavior to gamepad and remote control input. The following table lists these built-in mappings.

Expand table

Keyboard	Gamepad/remote
Arrow keys	D-pad (also left stick on gamepad)
Spacebar	A/Select button
Enter	A/Select button
Escape	B/Back button*

*When neither the KeyDown nor KeyUp events for the B button are handled by the app, the SystemNavigationManager.BackRequested event will be fired, which should result in back navigation within the app. However, you have to implement this yourself, as in the following code snippet:

C#

```
// This code goes in the MainPage class

public MainPage()
{
    this.InitializeComponent();

    // Handling Page Back navigation behaviors
    SystemNavigationManager.GetForCurrentView().BackRequested +=
        SystemNavigationManager_BackRequested;
}
```

```
private void SystemNavigationManager_BackRequested(
    object sender,
    BackRequestedEventArgs e)
{
    if (!e.Handled)
    {
        e.Handled = this.BackRequested();
    }
}

public Frame AppFrame { get { return this.Frame; } }

private bool BackRequested()
{
    // Get a hold of the current frame so that we can inspect the app back
stack
    if (this.AppFrame == null)
        return false;

    // Check to see if this is the top-most page on the app back stack
    if (this.AppFrame.CanGoBack)
    {
        // If not, set the event to handled and go back to the previous page
in the
        // app.
        this.AppFrame.GoBack();
        return true;
    }
    return false;
}
```

> ⓘ **Note**
>
> If the B button is used to go back, then don't show a back button in the UI. If you're using a Navigation view, the back button will be hidden automatically. For more information about backwards navigation, see Navigation history and backwards navigation for Windows apps.

Windows apps on Xbox One also support pressing the **Menu** button to open context menus. For more information, see CommandBar and ContextFlyout.

Accelerator support

Accelerator buttons are buttons that can be used to speed up navigation through a UI. However, these buttons may be unique to a certain input device, so keep in mind that not all users will be able to use these functions. In fact, gamepad is currently the only input device that supports accelerator functions for Windows apps on Xbox One.

The following table lists the accelerator support built into the UWP, as well as that which you can implement on your own. Utilize these behaviors in your custom UI to provide a consistent and friendly user experience.

Expand table

Interaction	Keyboard/Mouse	Gamepad	Built-in for:	Recommended for:
Page up/down	Page up/down	Left/right triggers	CalendarView, ListBox, ListViewBase, ListView, `ScrollViewer`, Selector, LoopingSelector, ComboBox, FlipView	Views that support vertical scrolling
Page left/right	None	Left/right bumpers	ListBox, ListViewBase, ListView, `ScrollViewer`, Selector, LoopingSelector, FlipView	Views that support horizontal scrolling
Zoom in/out	Ctrl +/-	Left/right triggers	None	`ScrollViewer`, views that support zooming in and out
Open/close nav pane	None	View	None	Navigation panes
Search	None	Y button	None	Shortcut to the main search function in the app
Open context menu	Right-click	Menu button	ContextFlyout	Context menus

XY focus navigation and interaction

If your app supports proper focus navigation for keyboard, this will translate well to gamepad and remote control. Navigation with the arrow keys is mapped to the **D-pad** (as well as the **left stick** on gamepad), and interaction with UI elements is mapped to the **Enter/Select** key (see Gamepad and remote control).

Many events and properties are used by both keyboard and gamepad—they both fire `KeyDown` and `KeyUp` events, and they both will only navigate to controls that have the properties `IsTabStop="True"` and `Visibility="Visible"`. For keyboard design guidance, see Keyboard interactions.

If keyboard support is implemented properly, your app will work reasonably well; however, there may be some extra work required to support every scenario. Think about your app's specific needs to provide the best user experience possible.

> **ⓘ Important**
>
> Mouse mode is enabled by default for Windows apps running on Xbox One. To disable mouse mode and enable XY focus navigation, set `Application.RequiresPointerMode=WhenRequested`.

Debugging focus issues

The FocusManager.GetFocusedElement method will tell you which element currently has focus. This is useful for situations where the location of the focus visual may not be obvious. You can log this information to the Visual Studio output window like so:

C#

```
page.GotFocus += (object sender, RoutedEventArgs e) =>
{
    FrameworkElement focus = FocusManager.GetFocusedElement() as
FrameworkElement;
    if (focus != null)
    {
        Debug.WriteLine("got focus: " + focus.Name + " (" +
            focus.GetType().ToString() + ")");
    }
};
```

There are three common reasons why XY navigation might not work the way you expect:

- The IsTabStop or Visibility property is set wrong.
- The control getting focus is actually bigger than you think—XY navigation looks at the total size of the control (ActualWidth and ActualHeight), not just the portion of the control that renders something interesting.
- One focusable control is on top of another—XY navigation doesn't support controls that are overlapped.

If XY navigation is still not working the way you expect after fixing these issues, you can manually point to the element that you want to get focus using the method described in Overriding the default navigation.

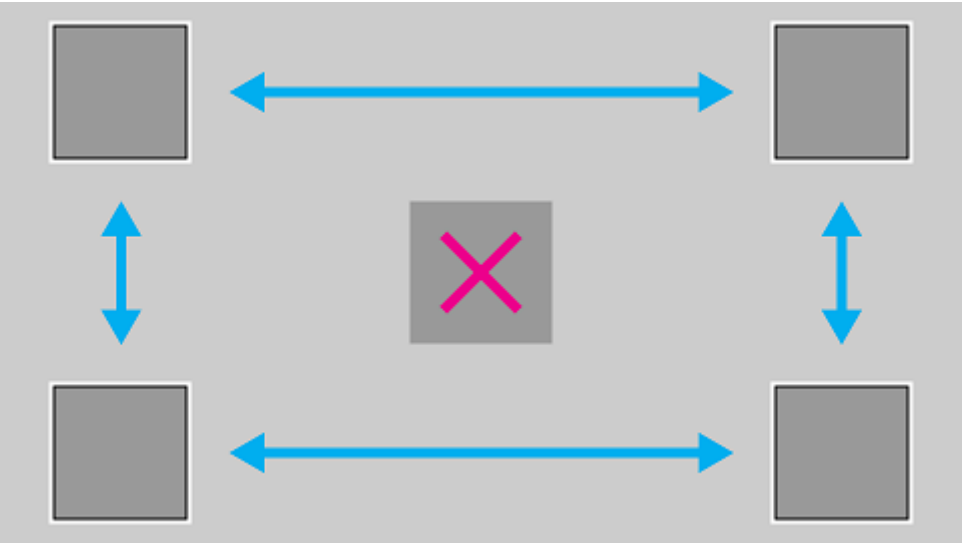
If XY navigation is working as intended but no focus visual is displayed, one of the following issues may be the cause:

- You re-templated the control and didn't include a focus visual. Set `UseSystemFocusVisuals="True"` or add a focus visual manually.
- You moved the focus by calling `Focus(FocusState.Pointer)`. The FocusState parameter controls what happens to the focus visual. Generally you should set this to `FocusState.Programmatic`, which keeps the focus visual visible if it was visible before, and hidden if it was hidden before.

The rest of this section goes into detail about common design challenges when using XY navigation, and offers several ways to solve them.

Inaccessible UI

Because XY focus navigation limits the user to moving up, down, left, and right, you may end up with scenarios where parts of the UI are inaccessible. The following diagram illustrates an example of the kind of UI layout that XY focus navigation doesn't support. Note that the element in the middle is not accessible by using gamepad/remote because the vertical and horizontal navigation will be prioritized and the middle element will never be high enough priority to get focus.



If for some reason rearranging the UI is not possible, use one of the techniques discussed in the next section to override the default focus behavior.

Overriding the default navigation

While the Universal Windows Platform tries to ensure that D-pad/left stick navigation makes sense to the user, it cannot guarantee behavior that is optimized for your app's intentions. The best way to ensure that navigation is optimized for your app is to test it with a gamepad and confirm that every UI element can be accessed by the user in a manner that makes sense for your app's scenarios. In case your app's scenarios call for a

behavior not achieved through the XY focus navigation provided, consider following the recommendations in the following sections and/or overriding the behavior to place the focus on a logical item.

The following code snippet shows how you might override the XY focus navigation behavior:

XML

```
<StackPanel>
    <Button x:Name="MyBtnLeft"
            Content="Search" />
    <Button x:Name="MyBtnRight"
            Content="Delete"/>
    <Button x:Name="MyBtnTop"
            Content="Update" />
    <Button x:Name="MyBtnDown"
            Content="Undo" />
    <Button Content="Home"
            XYFocusLeft="{x:Bind MyBtnLeft}"
            XYFocusRight="{x:Bind MyBtnRight}"
            XYFocusDown="{x:Bind MyBtnDown}"
            XYFocusUp="{x:Bind MyBtnTop}" />
</StackPanel>
```

In this case, when focus is on the `Home` button and the user navigates to the left, focus will move to the `MyBtnLeft` button; if the user navigates to the right, focus will move to the `MyBtnRight` button; and so on.

To prevent the focus from moving from a control in a certain direction, use the `XYFocus*` property to point it at the same control:

XML

```
<Button Name="HomeButton"
        Content="Home"
        XYFocusLeft ="{x:Bind HomeButton}" />
```

Using these `XYFocus` properties, a control parent can also force the navigation of its children when the next focus candidate is out of its visual tree, unless the child who has the focus uses the same `XYFocus` property.

XML

```
<StackPanel Orientation="Horizontal" Margin="300,300">
    <UserControl XYFocusRight="{x:Bind ButtonThree}">
        <StackPanel>
```

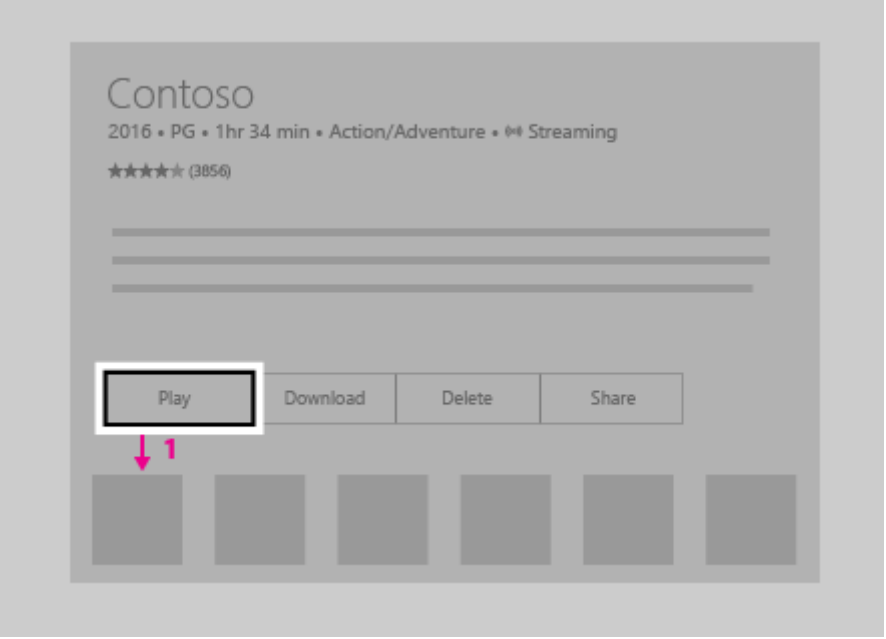
```
            <Button Content="One"/>
            <Button Content="Two"/>
        </StackPanel>
    </UserControl>
    <StackPanel>
        <Button x:Name="ButtonThree" Content="Three"/>
        <Button Content="Four"/>
    </StackPanel>
</StackPanel>
```

In the sample above, if the focus is on `Button` Two and the user navigates to the right, the best focus candidate is `Button` Four; however, the focus is moved to `Button` Three because the parent `UserControl` forces it to navigate there when it is out of its visual tree.

Path of least clicks

Try to allow the user to perform the most common tasks in the least number of clicks. In the following example, the TextBlock is placed between the **Play** button (which initially gets focus) and a commonly used element, so that an unnecessary element is placed in between priority tasks.

In the following example, the TextBlock is placed above the **Play** button instead. Simply rearranging the UI so that unnecessary elements are not placed in between priority tasks will greatly improve your app's usability.



CommandBar and ContextFlyout

When using a CommandBar, keep in mind the issue of scrolling through a list as mentioned in Problem: UI elements located after long scrolling list/grid. The following image shows a UI layout with the `CommandBar` on the bottom of a list/grid. The user would need to scroll all the way down through the list/grid to reach the `CommandBar`.

What if you put the `CommandBar` *above* the list/grid? While a user who scrolled down the list/grid would have to scroll back up to reach the `CommandBar`, it is slightly less navigation than the previous configuration. Note that this is assuming that your app's initial focus is placed next to or above the `CommandBar`; this approach won't work as well if the initial focus is below the list/grid. If these `CommandBar` items are global action items

that don't have to be accessed very often (such as a **Sync** button), it may be acceptable to have them above the list/grid.

While you can't stack a `CommandBar`'s items vertically, placing them against the scroll direction (for example, to the left or right of a vertically scrolling list, or the top or bottom of a horizontally scrolling list) is another option you may want to consider if it works well for your UI layout.

If your app has a `CommandBar` whose items need to be readily accessible by users, you may want to consider placing these items inside a ContextFlyout and removing them from the `CommandBar`. `ContextFlyout` is a property of UIElement and is the context menu associated with that element. On PC, when you right-click on an element with a `ContextFlyout`, that context menu will pop up. On Xbox One, this will happen when you press the **Menu** button while the focus is on such an element.

UI layout challenges

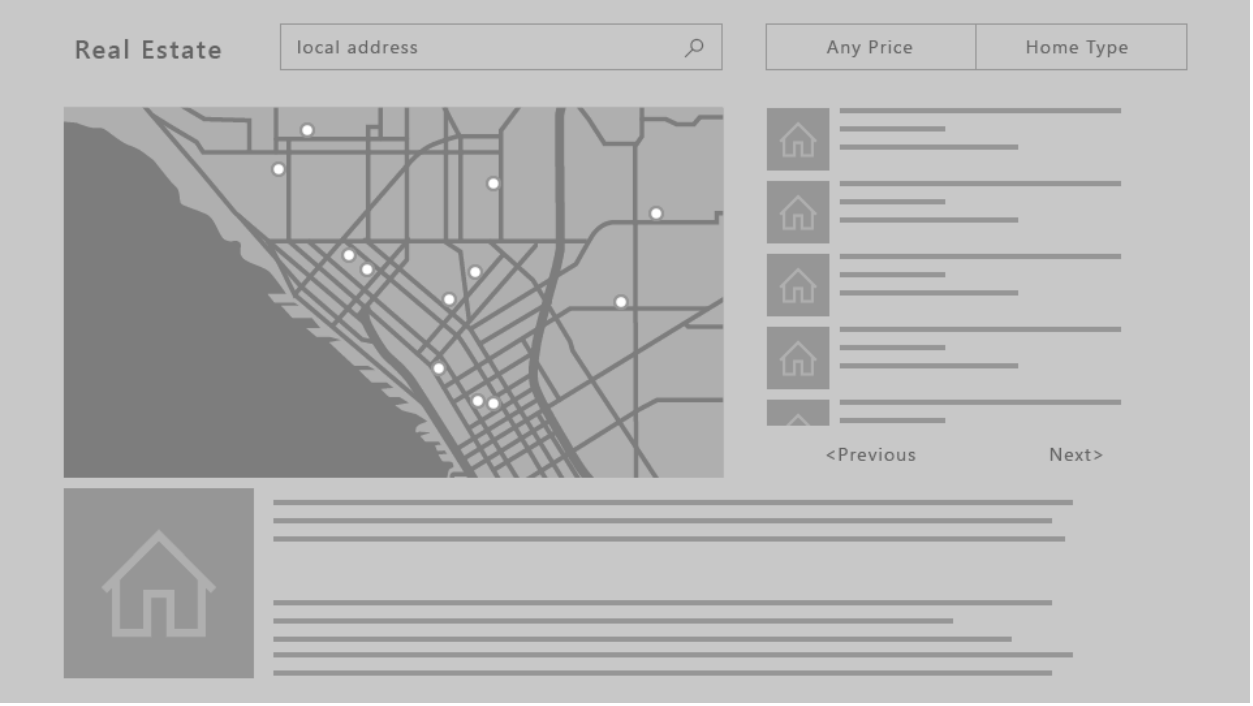
Some UI layouts are more challenging due to the nature of XY focus navigation, and should be evaluated on a case-by-case basis. While there is no single "right" way, and which solution you choose is up to your app's specific needs, there are some techniques that you can employ to make a great TV experience.

To understand this better, let's look at an imaginary app that illustrates some of these issues and techniques to overcome them.

> ⓘ **Note**
>
> This fake app is meant to illustrate UI problems and potential solutions to them, and is not intended to show the best user experience for your particular app.

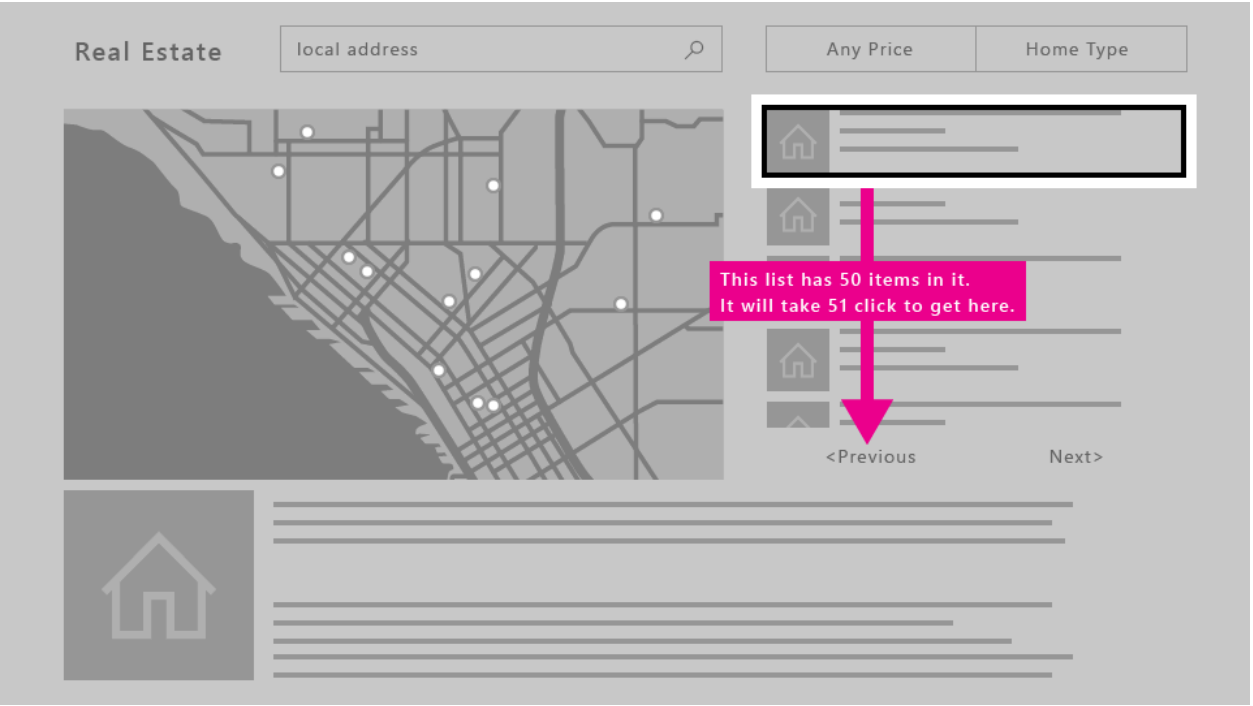
The following is an imaginary real estate app which shows a list of houses available for sale, a map, a description of a property, and other information. This app poses three challenges that you can overcome by using the following techniques:

- UI rearrange
- Focus engagement
- Mouse mode



Problem: UI elements located after long scrolling list/grid

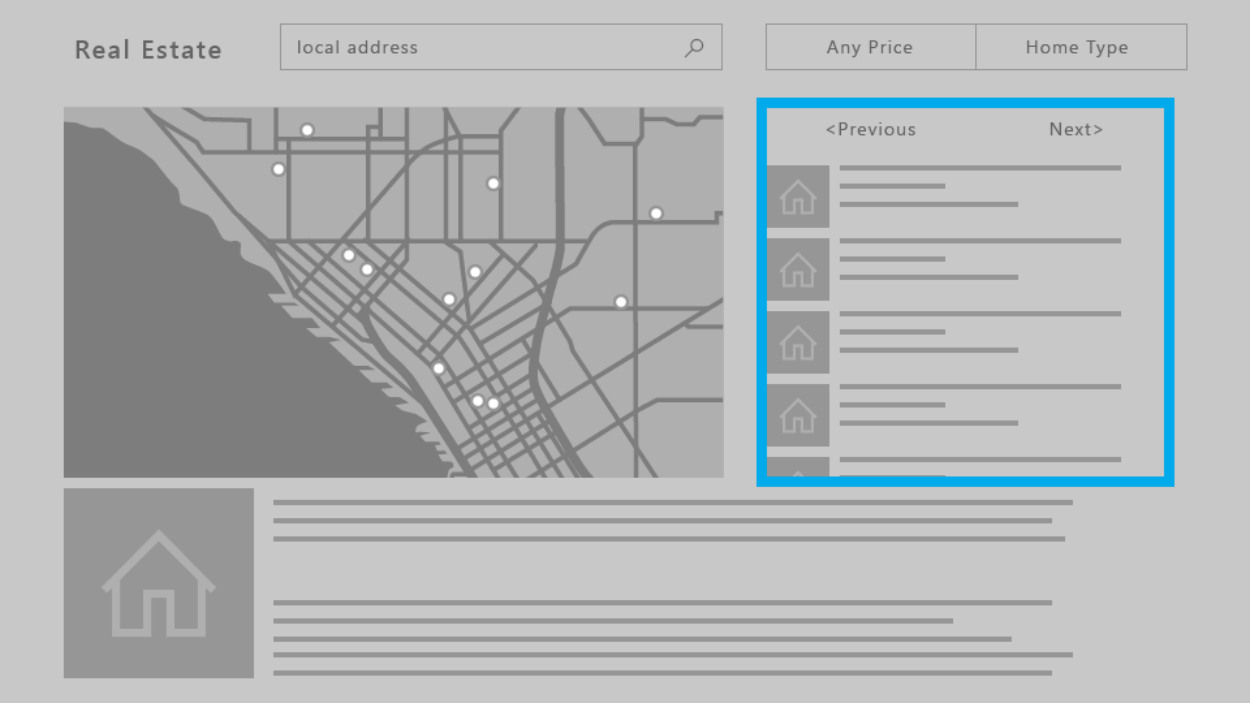
The ListView of properties shown in the following image is a very long scrolling list. If engagement is *not* required on the `ListView`, when the user navigates to the list, focus will be placed on the first item in the list. For the user to reach the **Previous** or **Next** button, they must go through all the items in the list. In cases like this where requiring the user to traverse the entire list is painful—that is, when the list is not short enough for this experience to be acceptable—you may want to consider other options.



Solutions

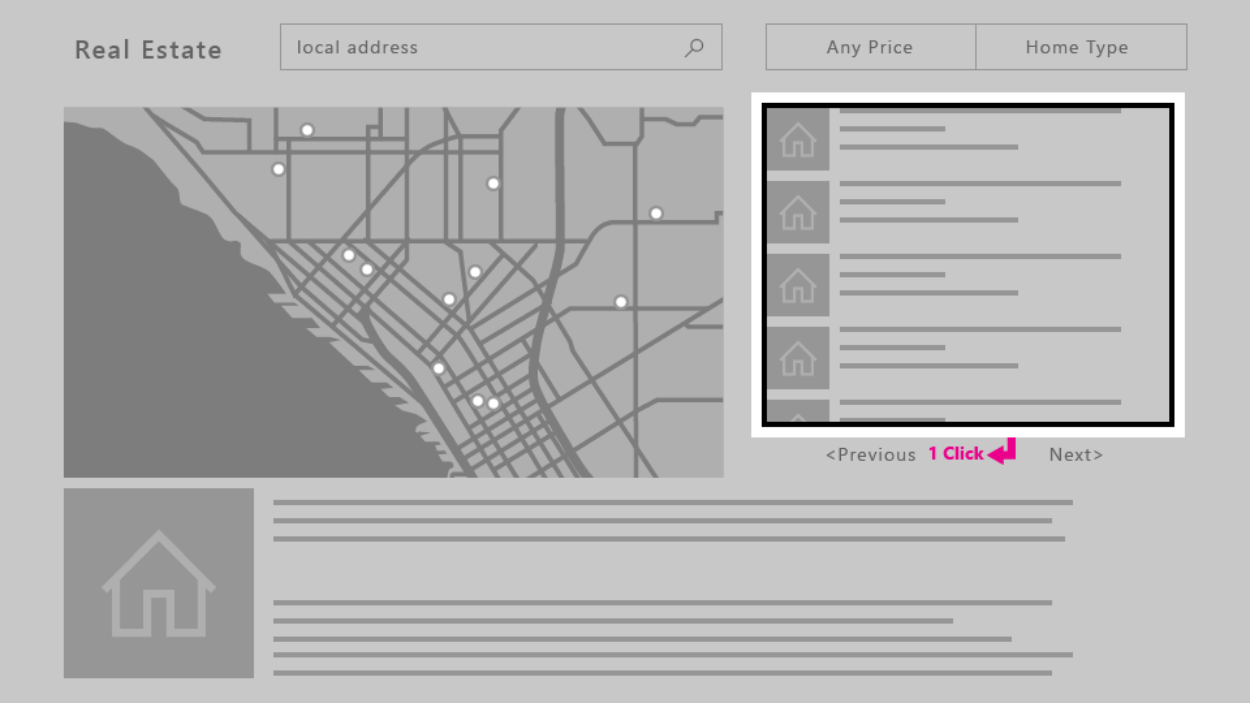
UI rearrange

Unless your initial focus is placed at the bottom of the page, UI elements placed above a long scrolling list are typically more easily accessible than if placed below. If this new layout works for other devices, changing the layout for all device families instead of doing special UI changes just for Xbox One might be a less costly approach. Additionally, placing UI elements against the scrolling direction (that is, horizontally to a vertically scrolling list, or vertically to a horizontally scrolling list) will make for even better accessibility.



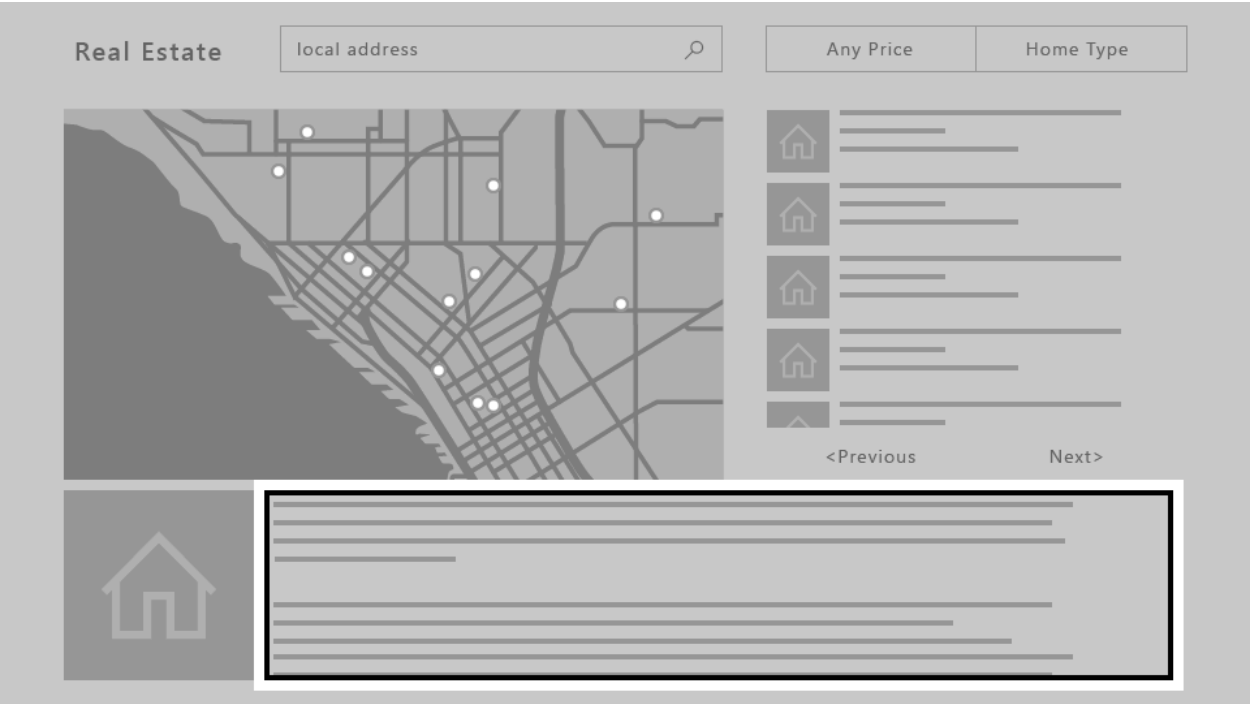
Focus engagement

When engagement is *required*, the entire `ListView` becomes a single focus target. The user will be able to bypass the contents of the list to get to the next focusable element. Read more about what controls support engagement and how to use them in Focus engagement.



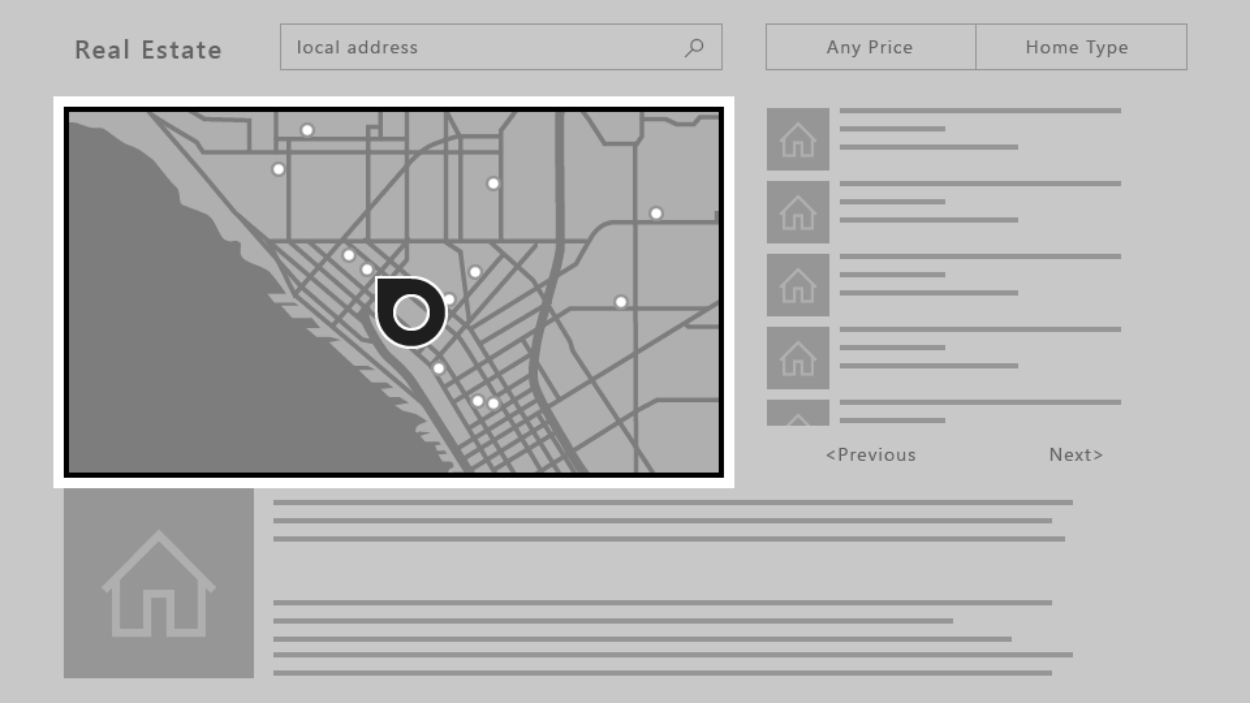
Problem: ScrollViewer without any focusable elements

Because XY focus navigation relies on navigating to one focusable UI element at a time, a ScrollViewer that doesn't contain any focusable elements (such as one with only text, as in this example) may cause a scenario where the user isn't able to view all of the content in the `ScrollViewer`. For solutions to this and other related scenarios, see Focus engagement.



Problem: Free-scrolling UI

When your app requires a freely scrolling UI, such as a drawing surface or, in this example, a map, XY focus navigation simply doesn't work. In such cases, you can turn on mouse mode to allow the user to navigate freely inside a UI element.



Mouse mode

As described in XY focus navigation and interaction, on Xbox One the focus is moved by using an XY navigation system, allowing the user to shift the focus from control to control by moving up, down, left, and right. However, some controls, such as WebView and MapControl, require a mouse-like interaction where users can freely move the pointer inside the boundaries of the control. There are also some apps where it makes sense for the user to be able to move the pointer across the entire page, having an experience with gamepad/remote similar to what users can find on a PC with a mouse.

For these scenarios, you should request a pointer (mouse mode) for the entire page, or on a control inside a page. For example, your app could have a page that has a `WebView` control that uses mouse mode only while inside the control, and XY focus navigation everywhere else. To request a pointer, you can specify whether you want it **when a control or page is engaged** or **when a page has focus**.

> **Note**
>
> Requesting a pointer when a control gets focus is not supported.

For both XAML and hosted web apps running on Xbox One, mouse mode is turned on by default for the entire app. It is highly recommended that you turn this off and

optimize your app for XY navigation. To do this, set the `Application.RequiresPointerMode` property to `WhenRequested` so that you only enable mouse mode when a control or page calls for it.

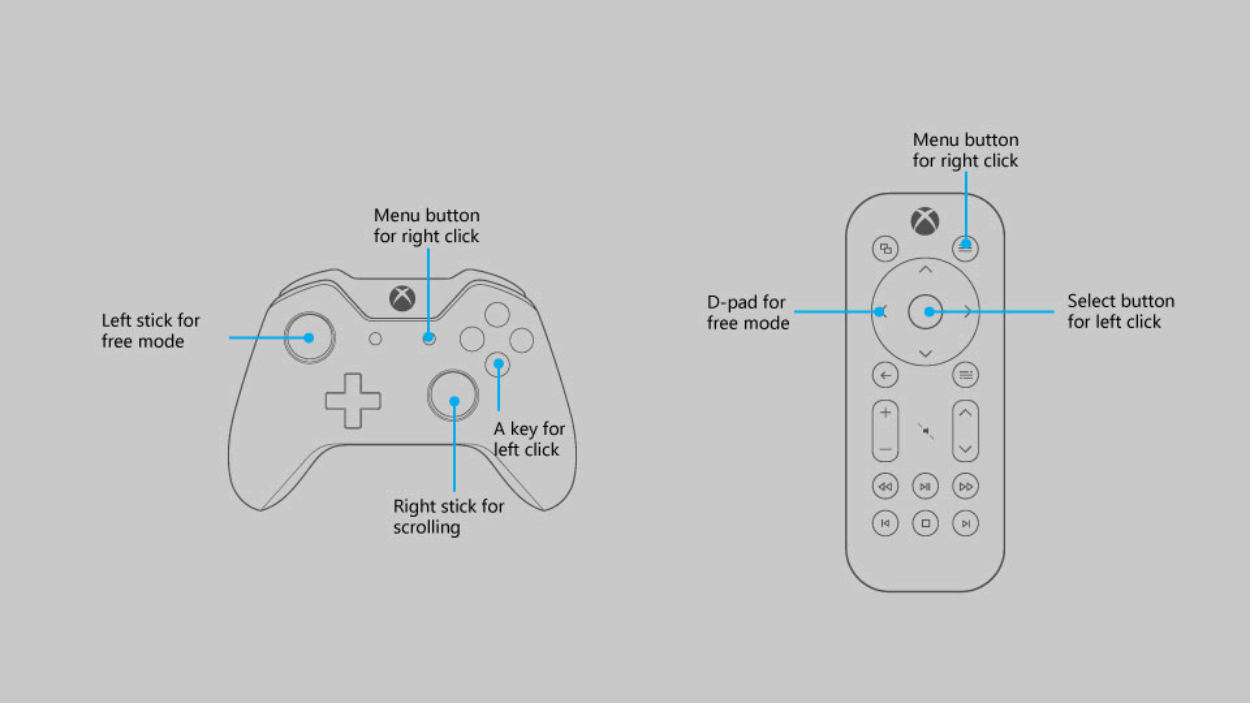
To do this in a XAML app, use the following code in your `App` class:

C#

```
public App()
{
    this.InitializeComponent();
    this.RequiresPointerMode =
        Windows.UI.Xaml.ApplicationRequiresPointerMode.WhenRequested;
    this.Suspending += OnSuspending;
}
```

For more information, including sample code for HTML/JavaScript, see How to disable mouse mode.

The following diagram shows the button mappings for gamepad/remote in mouse mode.



> **Note**
>
> Mouse mode is only supported on Xbox One with gamepad/remote. On other device families and input types it is silently ignored.

Use the RequiresPointer property on a control or page to activate mouse mode on it. This property has three possible values: `Never` (the default value), `WhenEngaged`, and `WhenFocused`.

Activating mouse mode on a control

When the user engages a control with `RequiresPointer="WhenEngaged"`, mouse mode is activated on the control until the user disengages it. The following code snippet demonstrates a simple `MapControl` that activates mouse mode when engaged:

XML

```
<Page>
    <Grid>
        <MapControl IsEngagementRequired="true"
                    RequiresPointer="WhenEngaged"/>
    </Grid>
</Page>
```

> **Note**
>
> If a control activates mouse mode when engaged, it must also require engagement with `IsEngagementRequired="true"`; otherwise, mouse mode will never be activated.

When a control is in mouse mode, its nested controls will be in mouse mode as well. The requested mode of its children will be ignored—it's impossible for a parent to be in mouse mode but a child not to be.

Additionally, the requested mode of a control is only inspected when it gets focus, so the mode won't change dynamically while it has focus.

Activating mouse mode on a page

When a page has the property `RequiresPointer="WhenFocused"`, mouse mode will be activated for the whole page when it gets focus. The following code snippet demonstrates giving a page this property:

XML

```
<Page RequiresPointer="WhenFocused">
    ...
</Page>
```

> **Note**
>
> The `WhenFocused` value is only supported on **Page** objects. If you try to set this value on a control, an exception will be thrown.

Disabling mouse mode for full screen content

Usually when displaying video or other types of content in full screen, you will want to hide the cursor because it can distract the user. This scenario occurs when the rest of the app uses mouse mode, but you want to turn it off when showing full screen content. To accomplish this, put the full screen content on its own `Page`, and follow the steps below.

1. In the `App` object, set `RequiresPointerMode="WhenRequested"`.
2. In every `Page` object *except* for the full screen `Page`, set `RequiresPointer="WhenFocused"`.
3. For the full screen `Page`, set `RequiresPointer="Never"`.

This way, the cursor will never appear when showing full screen content.

Focus visual

The focus visual is the border around the UI element that currently has focus. This helps orient the user so that they can easily navigate your UI without getting lost.

With a visual update and numerous customization options added to focus visual, developers can trust that a single focus visual will work well on PCs and Xbox One, as well as on any other Windows devices that support keyboard and/or gamepad/remote.

While the same focus visual can be used across different platforms, the context in which the user encounters it is slightly different for the 10-foot experience. You should assume that the user is not paying full attention to the entire TV screen, and therefore it is important that the currently focused element is clearly visible to the user at all times to avoid the frustration of searching for the visual.

It is also important to keep in mind that the focus visual is displayed by default when using a gamepad or remote control, but *not* a keyboard. Thus, even if you don't implement it, it will appear when you run your app on Xbox One.

Initial focus visual placement

When launching an app or navigating to a page, place the focus on a UI element that makes sense as the first element on which the user would take action. For example, a photo app may place focus on the first item in the gallery, and a music app navigated to a detailed view of a song might place focus on the play button for ease of playing music.

Try to put initial focus in the top left region of your app (or top right for a right-to-left flow). Most users tend to focus on that corner first because that's where app content flow generally begins.

Making focus clearly visible

One focus visual should always be visible on the screen so that the user can pick up where they left off without searching for the focus. Similarly, there should be a focusable item onscreen at all times—for example, don't use pop-ups with only text and no focusable elements.

An exception to this rule would be for full-screen experiences, such as watching videos or viewing images, in which cases it would not be appropriate to show the focus visual.

Reveal focus

Reveal focus is a lighting effect that animates the border of focusable elements, such as a button, when the user moves gamepad or keyboard focus to them. By animating the glow around the border of the focused elements, Reveal focus gives users a better understanding of where focus is and where focus is going.

Reveal focus is off by default. For 10 foot experiences you should opt-in to reveal focus by setting the Application.FocusVisualKind property in your app constructor.

C#

```
    if(AnalyticsInfo.VersionInfo.DeviceFamily == "Windows.Xbox")
    {
        this.FocusVisualKind = FocusVisualKind.Reveal;
    }
```

For more information see the guidance for Reveal focus.

Customizing the focus visual

If you'd like to customize the focus visual, you can do so by modifying the properties related to the focus visual for each control. There are several such properties that you

can take advantage of to personalize your app.

You can even opt out of the system-provided focus visuals by drawing your own using visual states. To learn more, see VisualState.

Light dismiss overlay

To call the user's attention to the UI elements that the user is currently manipulating with the game controller or remote control, UWP automatically adds a "smoke" layer that covers areas outside of the popup UI when the app is running on Xbox One. This requires no extra work, but is something to keep in mind when designing your UI. You can set the `LightDismissOverlayMode` property on any `FlyoutBase` to enable or disable the smoke layer; it defaults to `Auto`, meaning that it is enabled on Xbox and disabled elsewhere. For more information, see Modal vs light dismiss.

Focus engagement

Focus engagement is intended to make it easier to use a gamepad or remote to interact with an app.

> ⓘ **Note**
>
> Setting focus engagement does not impact keyboard or other input devices.

When the property `IsFocusEngagementEnabled` on a FrameworkElement object is set to `True`, it marks the control as requiring focus engagement. This means that the user must press the **A/Select** button to "engage" the control and interact with it. When they are finished, they can press the **B/Back** button to disengage the control and navigate out of it.

> ⓘ **Note**
>
> `IsFocusEngagementEnabled` is a new API and not yet documented.

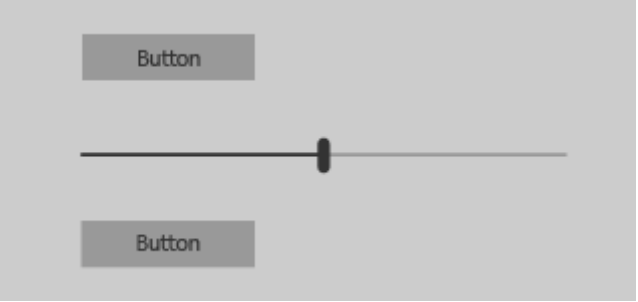
Focus trapping

Focus trapping is what happens when a user attempts to navigate an app's UI but becomes "trapped" within a control, making it difficult or even impossible to move outside of that control.

The following example shows UI that creates focus trapping.

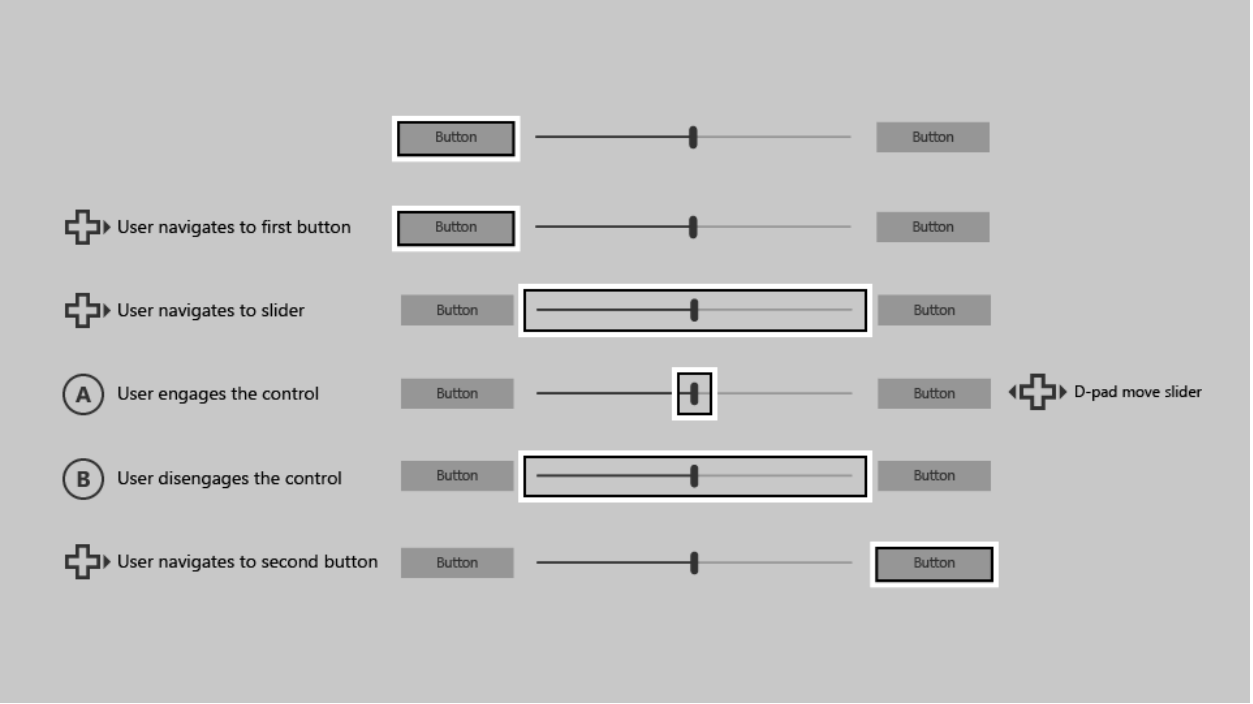
If the user wants to navigate from the left button to the right button, it would be logical to assume that all they'd have to do is press right on the D-pad/left stick twice. However, if the Slider doesn't require engagement, the following behavior would occur: when the user presses right the first time, focus would shift to the `Slider`, and when they press right again, the `Slider`'s handle would move to the right. The user would keep moving the handle to the right and wouldn't be able to get to the button.

There are several approaches to getting around this issue. One is to design a different layout, similar to the real estate app example in XY focus navigation and interaction where we relocated the **Previous** and **Next** buttons above the `ListView`. Stacking the controls vertically instead of horizontally as in the following image would solve the problem.



Now the user can navigate to each of the controls by pressing up and down on the D-pad/left stick, and when the `Slider` has focus, they can press left and right to move the `Slider` handle, as expected.

Another approach to solving this problem is to require engagement on the `Slider`. If you set `IsFocusEngagementEnabled="True"`, this will result in the following behavior.



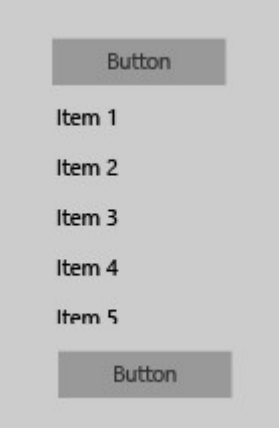
When the `Slider` requires focus engagement, the user can get to the button on the right simply by pressing right on the D-pad/left stick twice. This solution is great because it requires no UI adjustment and produces the expected behavior.

Items controls

Aside from the Slider control, there are other controls which you may want to require engagement, such as:

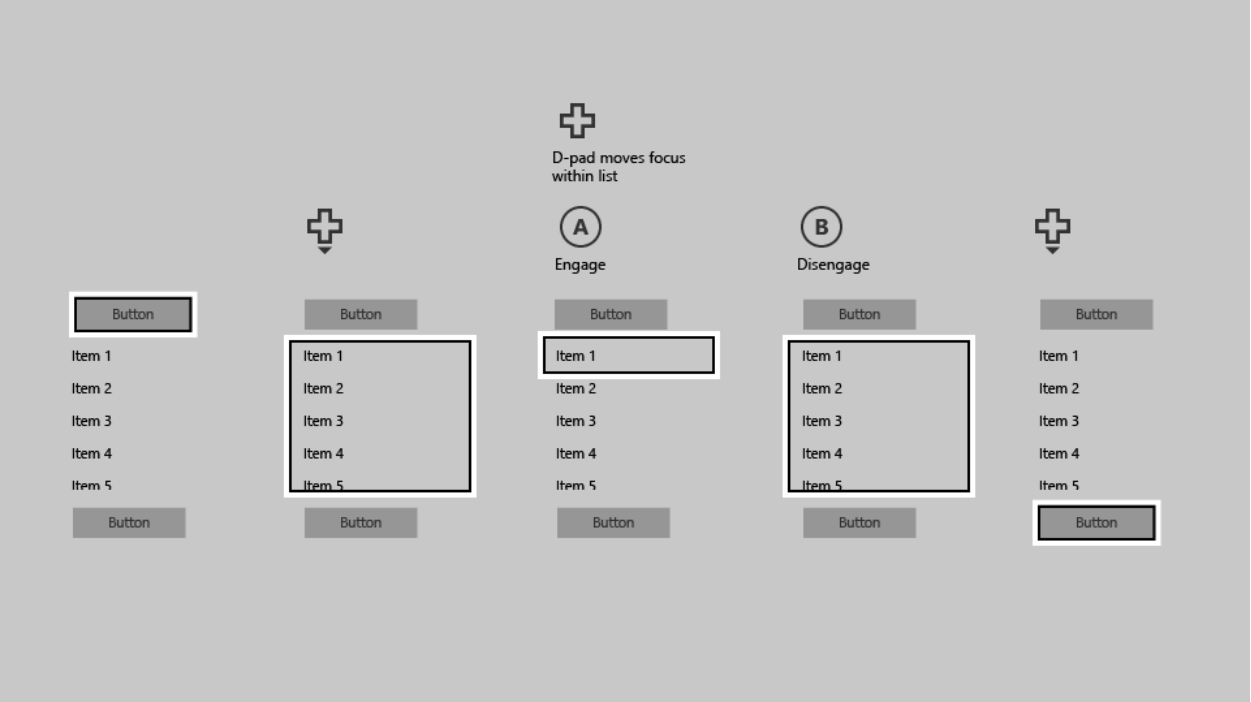
- ListBox
- ListView
- GridView
- FlipView

Unlike the `Slider` control, these controls don't trap focus within themselves; however, they can cause usability issues when they contain large amounts of data. The following is an example of a `ListView` that contains a large amount of data.



Similar to the `Slider` example, let's try to navigate from the button at the top to the button at the bottom with a gamepad/remote. Starting with focus on the top button, pressing down on the D-pad/stick will place the focus on the first item in the `ListView` ("Item 1"). When the user presses down again, the next item in the list gets focus, not the button on the bottom. To get to the button, the user must navigate through every item in the `ListView` first. If the `ListView` contains a large amount of data, this could be inconvenient and not an optimal user experience.

To solve this problem, set the property `IsFocusEngagementEnabled="True"` on the `ListView` to require engagement on it. This will allow the user to quickly skip over the `ListView` by simply pressing down. However, they will not be able to scroll through the list or choose an item from it unless they engage it by pressing the **A/Select** button when it has focus, and then pressing the **B/Back** button to disengage.



ScrollViewer

Slightly different from these controls is the ScrollViewer, which has its own quirks to consider. If you have a `ScrollViewer` with focusable content, by default navigating to the `ScrollViewer` will allow you to move through its focusable elements. Like in a `ListView`, you must scroll through each item to navigate outside of the `ScrollViewer`.

If the `ScrollViewer` has *no* focusable content—for example, if it only contains text—you can set `IsFocusEngagementEnabled="True"` so the user can engage the `ScrollViewer` by using the **A/Select** button. After they have engaged, they can scroll through the text by using the **D-pad/left stick**, and then press the **B/Back** button to disengage when they're finished.

Another approach would be to set `IsTabStop="True"` on the `ScrollViewer` so that the user doesn't have to engage the control—they can simply place focus on it and then scroll by using the **D-pad/left stick** when there are no focusable elements within the `ScrollViewer`.

Focus engagement defaults

Some controls cause focus trapping commonly enough to warrant their default settings to require focus engagement, while others have focus engagement turned off by default but can benefit from turning it on. The following table lists these controls and their default focus engagement behaviors.

Expand table

Control	Focus engagement default
CalendarDatePicker	On
FlipView	Off
GridView	Off
ListBox	Off
ListView	Off
ScrollViewer	Off
SemanticZoom	Off
Slider	On

All other Windows controls will result in no behavioral or visual changes when `IsFocusEngagementEnabled="True"`.

Summary

You can build Windows applications that are optimized for a specific device or experience, but the Universal Windows Platform also enables you to build apps that can be used successfully across devices, in both 2-foot and 10-foot experiences, and regardless of input device or user ability. Using the recommendations in this article can ensure that your app is as good as it can be on both the TV and a PC.

Touchpad design guidelines

Article • 06/24/2021

Design your app so that users can interact with it through a touchpad. A touchpad combines both indirect multi-touch input with the precision input of a pointing device, such as a mouse. This combination makes the touchpad suited to both a touch-optimized UI and the smaller targets of productivity apps.

Touchpad interactions require three things:

- A standard touchpad or a Windows Precision Touchpad.

  Precision touchpads are optimized for Windows app devices. They enable the system to handle certain aspects of the touchpad experience natively, such as finger tracking and palm detection, for a more consistent experience across devices.

- The direct contact of one or more fingers on the touchpad.

- Movement of the touch contacts (or lack thereof, based on a time threshold).

The input data provided by the touchpad sensor can be:

- Interpreted as a physical gesture for direct manipulation of one or more UI elements (such as panning, rotating, resizing, or moving). In contrast, interacting with an element through its properties window or other dialog box is considered indirect manipulation.
- Recognized as an alternative input method, such as mouse or pen.
- Used to complement or modify aspects of other input methods, such as smudging an ink stroke drawn with a pen.

A touchpad combines indirect multi-touch input with the precision input of a pointing device, such as a mouse. This combination makes the touchpad suited to both touch-optimized UI and the typically smaller targets of productivity apps and the desktop environment. Optimize your Windows app design for touch input and get touchpad support by default.

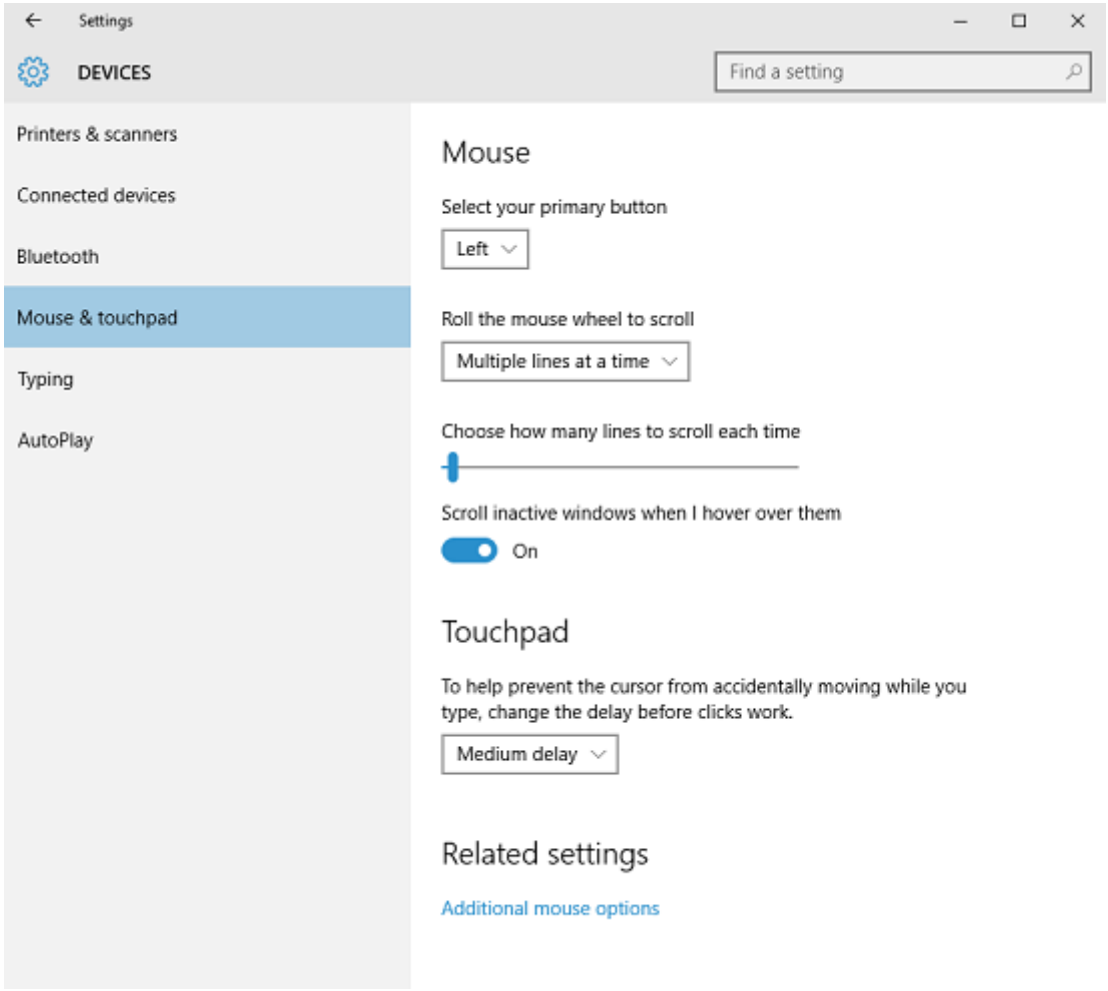
Because of the convergence of interaction experiences supported by touchpads, we recommend using the **PointerEntered** event to provide mouse-style UI commands in addition to the built-in support for touch input. For example, use previous and next buttons to let users flip through pages of content as well as pan through the content.

The gestures and guidelines discussed in this topic can help to ensure that your app supports touchpad input seamlessly and with minimal code.

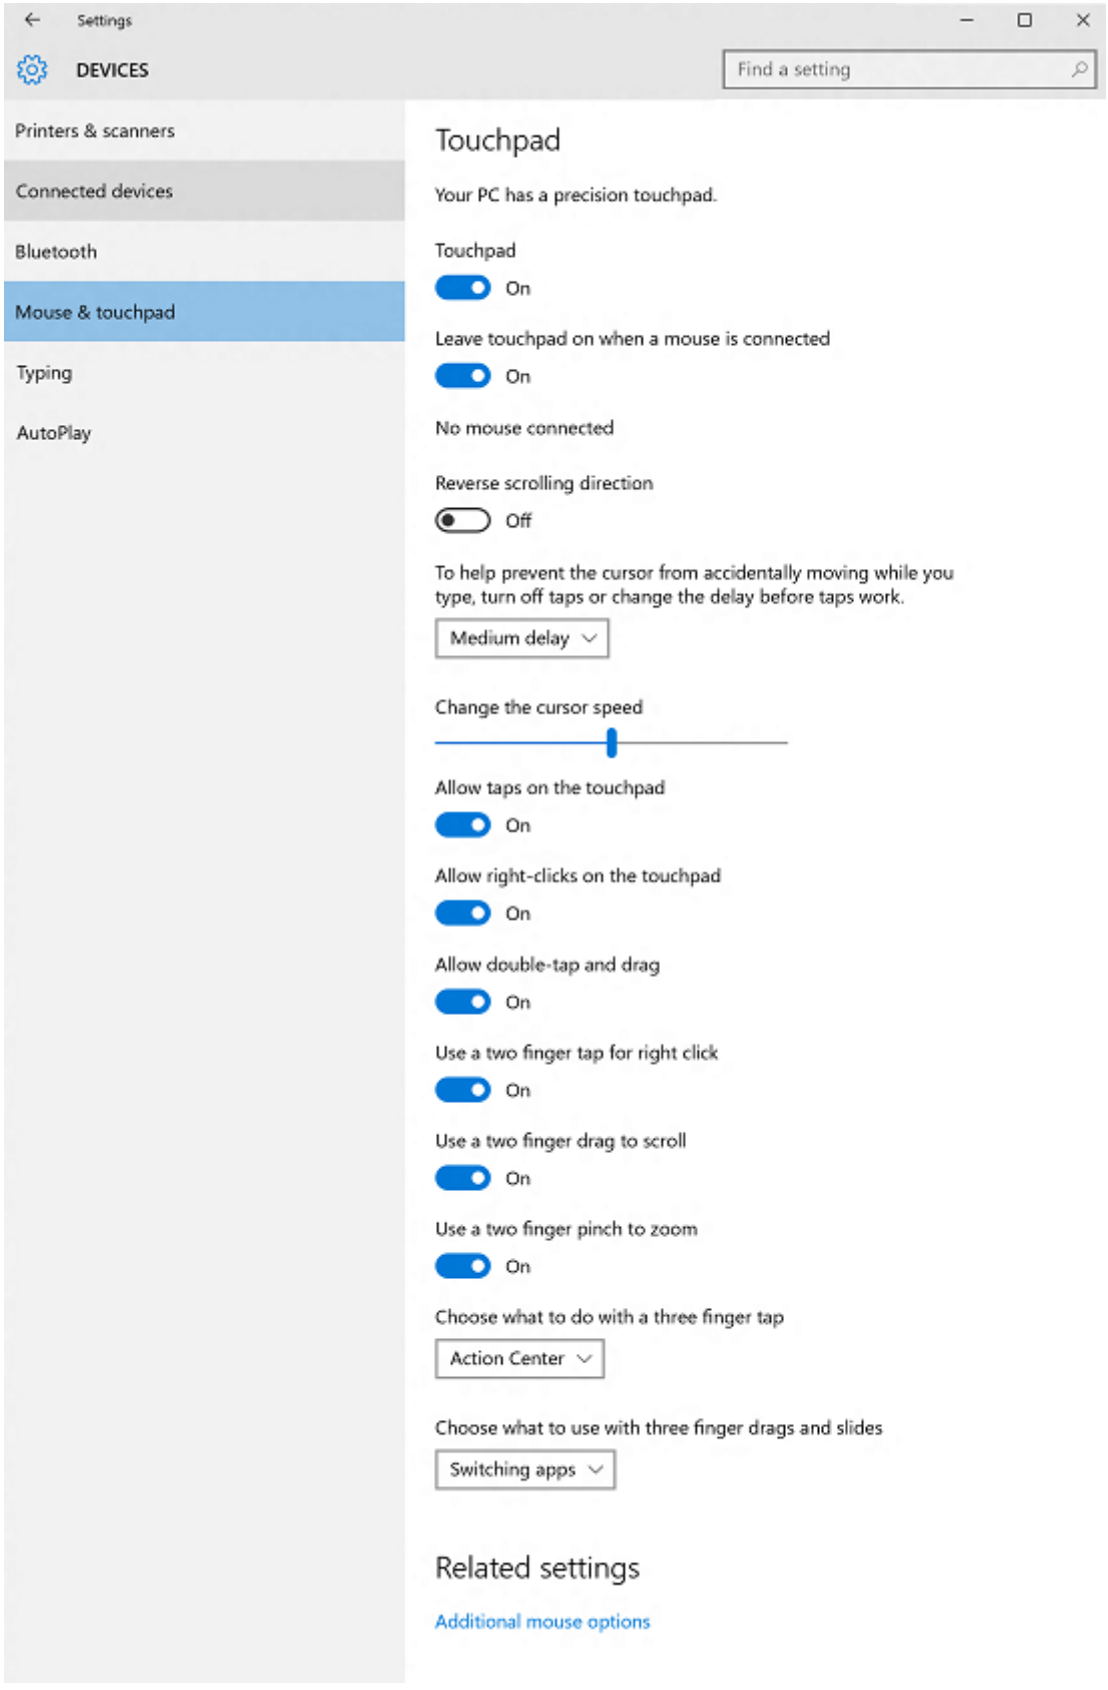
The touchpad language

A concise set of touchpad interactions are used consistently throughout the system. Optimize your app for touch and mouse input and this language makes your app feel instantly familiar for your users, increasing their confidence and making your app easier to learn and use.

Users can set far more Precision Touchpad gestures and interaction behaviors than they can for a standard touchpad. These two images show the different touchpad settings pages from Settings > Devices > Mouse & touchpad for a standard touchpad and a Precision Touchpad, respectively.



Standard\ touchpad\ settings



Windows\ Precision\ Touchpad\ settings

Here are some examples of touchpad-optimized gestures for performing common tasks.

Term	Description
Three-finger tap	User preference to search with **Cortana** or show **Action Center**.

Term	Description
Three finger slide	User preference to open the virtual desktop Task View, show Desktop, or switch between open apps.
Single finger tap for primary action	Use a single finger to tap an element and invoke its primary action (such as launching an app or executing a command).
Two finger tap to right-click	Tap with two fingers simultaneously on an element to select it and display contextual commands.
Two finger slide to pan	Slide is used primarily for panning interactions but can also be used for moving, drawing, or writing.
Pinch and stretch to zoom	The pinch and stretch gestures are commonly used for resizing and Semantic Zoom.
Single finger press and slide to rearrange	Drag an element.
Single finger press and slide to select text	Press within selectable text and slide to select it. Double-tap to select a word.
Left and right click zone	Emulate the left and right button functionality of a mouse device.

Hardware

Query the mouse device capabilities (**MouseCapabilities**) to identify what aspects of your app UI the touchpad hardware can access directly. We recommend providing UI for both touch and mouse input.

For more info about querying device capabilities, see Identify input devices.

Visual feedback

- When a touchpad cursor is detected (through move or hover events), show mouse-specific UI to indicate functionality exposed by the element. If the touchpad cursor doesn't move for a certain amount of time, or if the user initiates a touch interaction, make the touchpad UI gradually fade away. This keeps the UI clean and uncluttered.

- Don't use the cursor for hover feedback, the feedback provided by the element is sufficient (see the Cursors section below).
- Don't display visual feedback if an element doesn't support interaction (such as static text).
- Don't use focus rectangles with touchpad interactions. Reserve these for keyboard interactions.
- Display visual feedback concurrently for all elements that represent the same input target.

For more general guidance about visual feedback, see Guidelines for visual feedback.

Cursors

A set of standard cursors is available for a touchpad pointer. These are used to indicate the primary action of an element.

Each standard cursor has a corresponding default image associated with it. The user or an app can replace the default image associated with any standard cursor at any time. UWP apps specify a cursor image through the **PointerCursor** function.

If you need to customize the mouse cursor:

- Always use the arrow cursor ( ) for clickable elements. don't use the pointing hand cursor ( ) for links or other interactive elements. Instead, use hover effects (described earlier).
- Use the text cursor ( ) for selectable text.
- Use the move cursor ( ) when moving is the primary action (such as dragging or cropping). Don't use the move cursor for elements where the primary action is navigation (such as Start tiles).
- Use the horizontal, vertical and diagonal resize cursors (), when an object is resizable.
- Use the grasping hand cursors ( ) when panning content within a fixed canvas (such as a map).

Surface Dial interactions

Article • 10/06/2022

Surface Dial with Surface Studio and Pen (available for purchase at the Microsoft Store).

Overview

Windows wheel devices, such as the Surface Dial, are a new category of input device that enable a host of compelling and unique user interaction experiences for Windows and Windows apps.

> **Important**
>
> In this topic, we refer specifically to Surface Dial interactions, but the info is applicable to all Windows wheel devices.

With a form factor based on a *rotate* action (or gesture), the Surface Dial is intended as a secondary, multi-modal input device that complements input from a primary device. In most cases, the device is manipulated by a user's non-dominant hand while performing a task with their dominant hand (such as inking with a pen). It is not designed for precision pointer input (like touch, pen, or mouse).

The Surface Dial also supports both a *press and hold* action and a *click* action. Press and hold has a single function: display a menu of commands. If the menu is active, the rotate and click input is processed by the menu. Otherwise, the input is passed to your app for processing.

As with all Windows input devices, you can customize and tailor the Surface Dial interaction experience to suit the functionality in your apps.

Tip

Used together, the Surface Dial and the new Surface Studio can provide an even more distinctive user experience.

In addition to the default press and hold menu experience described, the Surface Dial can also be placed directly on the screen of the Surface Studio. This enables a special "on-screen" menu.

By detecting both the contact location and bounds of the Surface Dial, the system uses this info to handle occlusion by the device and display a larger version of the menu that wraps around the outside of the Dial. This same info can also be used by your app to adapt the UI for both the presence of the device and its anticipated usage, such as the placement of the user's hand and arm.

Surface Dial off-screen menu

Surface Dial on-screen menu

System integration

The Surface Dial is tightly integrated with Windows and supports a set of built-in tools on the menu: system volume, scroll, zoom in/out, and undo/redo.

This collection of built-in tools adapts to the current system context to include:

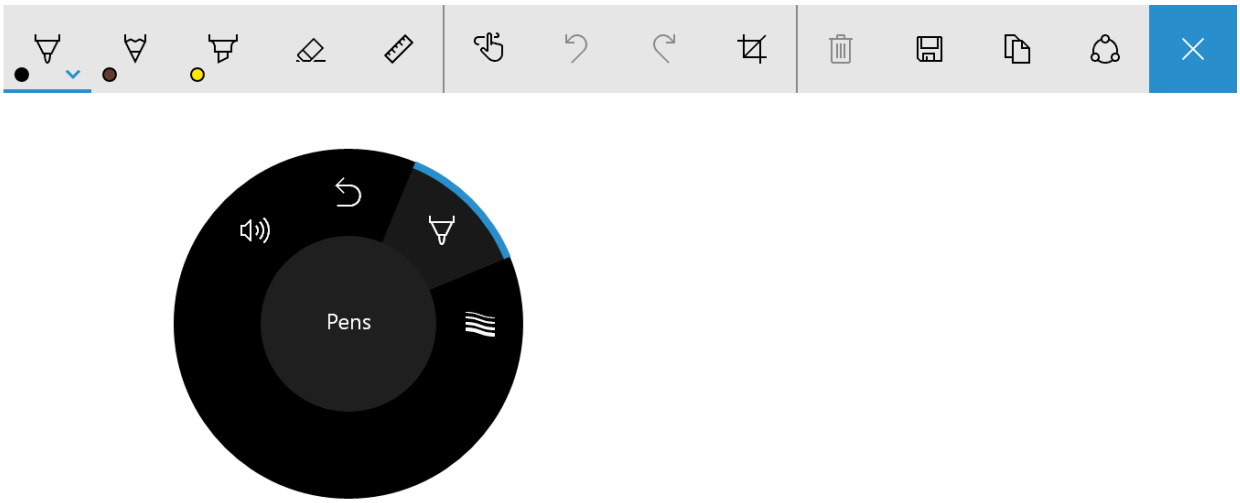
- A system brightness tool when the user is on the Windows Desktop
- A previous/next track tool when media is playing

In addition to this general platform support, the Surface Dial is also tightly integrated with the Windows Ink platform controls (**InkCanvas** and **InkToolbar**).

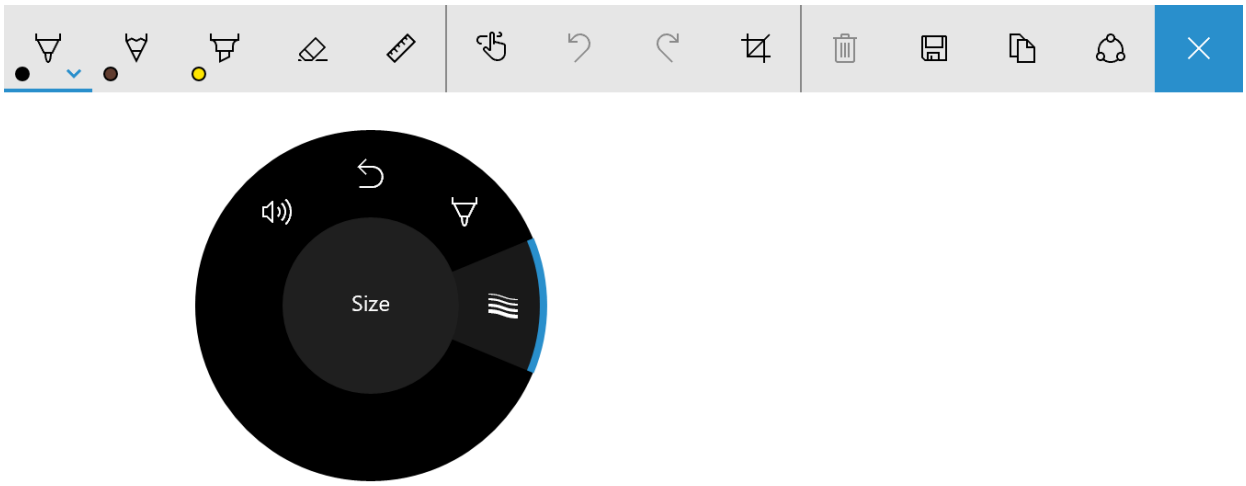
Surface Dial with Surface Pen

When used with the Surface Dial, these controls enable additional functionality for modifying ink attributes and controlling the ink toolbar's ruler stencil.

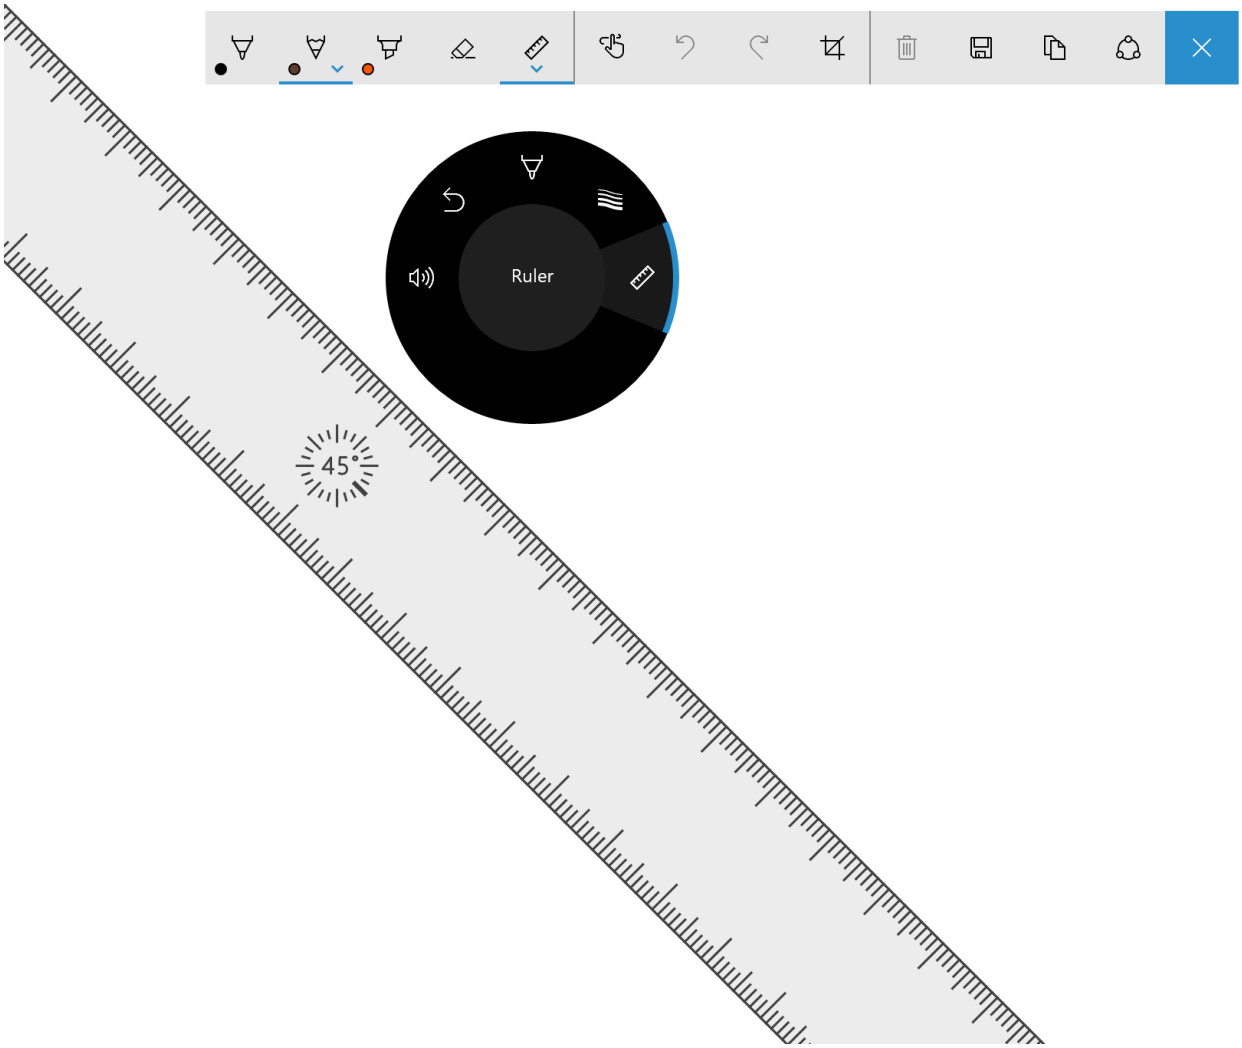
When you open the Surface Dial Menu in an inking application that uses the ink toolbar, the menu now includes tools for controlling pen type and brush thickness. When the ruler is enabled, a corresponding tool is added to the menu that lets the device control the position and angle of the ruler.



Surface Dial menu with pen selection tool for the Windows Ink toolbar



Surface Dial menu with stroke size tool for the Windows Ink toolbar



Surface Dial menu with ruler tool for the Windows Ink toolbar

User customization

Users can customize some aspects of their Dial experience through the **Windows Settings** -> **Devices** -> **Wheel** page, including default tools, vibration (or haptic feedback), and writing (or dominant) hand.

When customizing the Surface Dial user experience, you should always ensure that a particular function or behavior is available and enabled by the user.

Custom tools

Here we discuss both UX and developer guidance for customizing the tools exposed on the Surface Dial menu.

UX guidance for custom tools

Ensure your tools correspond to the current context When you make it clear and intuitive what a tool does and how the Surface Dial interaction works, you help users learn quickly and stay focused on their task.

Minimize the number of app tools as much as possible
The Surface Dial menu has room for seven items. If there are eight or more items, the user needs to turn the Dial to see which tools are available in an overflow flyout, making the menu difficult to navigate and tools difficult to discover and select.

We recommend providing a single custom tool for your app or app context. Doing so enables you to set that tool based on what the user is doing without requiring them to activate the Surface Dial menu and select a tool.

Dynamically update the collection of tools
Because Surface Dial menu items do not support a disabled state, you should dynamically add and remove tools (including built-in, default tools) based on user context (current view or focused window). If a tool is not relevant to the current activity or it's redundant, remove it.

> **ⓘ Important**
>
> When you add an item to the menu, ensure the item does not already exist.

Don't remove the built-in system volume setting tool
Volume control is typically always required by user. They might be listening to music while using your app, so volume and next track tools should always be accessible from the Surface Dial menu. (The next track tool is automatically added to the menu when media is playing.)

Be consistent with menu organization
This helps users with discovering and learning what tools are available when using your

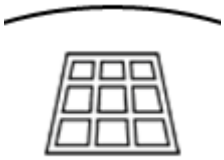
app, and helps improve their efficiency when switching tools.

Provide high-quality icons consistent with the built-in icons
Icons can convey professionalism and excellence, and inspire trust in users.

- Provide a high-quality 64 x 64 pixel PNG image (44 x 44 is the smallest supported)
- Ensure the background is transparent
- The icon should fill most of the image
- A white icon should have a black outline to be visible in high contrast mode

Icon with alpha background

Icon displayed on wheel menu with default theme



Icon displayed on wheel menu with High Contrast White theme

Use concise and descriptive names
The tool name is displayed in the tool menu along with the tool icon and is also used by screen readers.

- Names should be short to fit inside the central circle of the wheel menu
- Names should clearly identify the primary action (a complementary action can be implied):
  - Scroll indicates the effect of both rotation directions
  - Undo specifies a primary action, but redo (the complementary action) can be inferred and easily discovered by the user

Developer guidance

You can customize the Surface Dial experience to complement the functionality in your apps through a comprehensive set of Windows Runtime APIs.

As previously mentioned, the default Surface Dial menu is pre-populated with a set of built-in tools covering a broad range of basic system features (system volume, system brightness, scroll, zoom, undo, and media control when the system detects ongoing audio or video playback). However, these default tools might not provide the functionality required by your app.

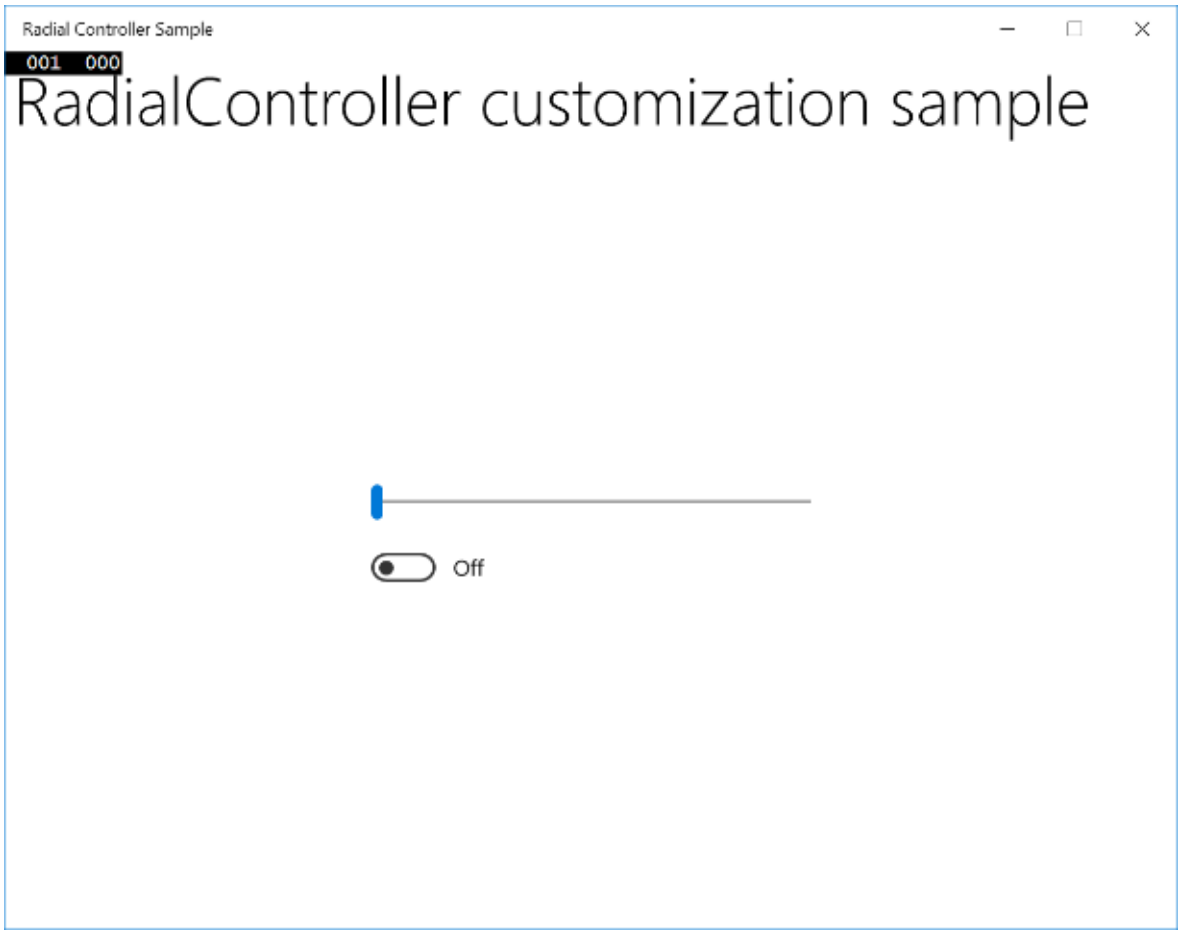
In the following sections, we describe how to add a custom tool to the Surface Dial menu and specify which built-in tools are exposed.

Download a more robust version of this sample from RadialController customization.

Add a custom tool

In this example, we add a basic custom tool that passes the input data from both the rotation and click events to some XAML UI controls.

1. First, we declare our UI (just a slider and toggle button) in XAML.



The sample app UI

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
  <Grid.RowDefinitions>
    <RowDefinition Height="Auto"/>
    <RowDefinition Height="*"/>
  </Grid.RowDefinitions>
  <StackPanel x:Name="HeaderPanel"
    Orientation="Horizontal"
    Grid.Row="0">
      <TextBlock x:Name="Header"
        Text="RadialController customization sample"
        VerticalAlignment="Center"
        Style="{ThemeResource HeaderTextBlockStyle}"
        Margin="10,0,0,0" />
  </StackPanel>
  <StackPanel Orientation="Vertical"
    VerticalAlignment="Center"
    HorizontalAlignment="Center"
    Grid.Row="1">
      <!-- Slider for rotation input -->
      <Slider x:Name="RotationSlider"
        Width="300"
        HorizontalAlignment="Left"/>
      <!-- Switch for click input -->
      <ToggleSwitch x:Name="ButtonToggle"
        HorizontalAlignment="Left"/>
  </StackPanel>
</Grid>
```

2. Then, in code-behind, we add a custom tool to the Surface Dial menu and declare the **RadialController** input handlers.

   We get a reference to the **RadialController** object for the Surface Dial (myController) by calling **CreateForCurrentView**.

   We then create an instance of a **RadialControllerMenuItem** (myItem) by calling **RadialControllerMenuItem.CreateFromIcon**.

   Next, we append that item to the collection of menu items.

   We declare the input event handlers (**ButtonClicked** and **RotationChanged**) for the **RadialController** object.

   Finally, we define the event handlers.

```
C#

public sealed partial class MainPage : Page
{
    RadialController myController;
```

```
    public MainPage()
    {
        this.InitializeComponent();
        // Create a reference to the RadialController.
        myController = RadialController.CreateForCurrentView();

        // Create an icon for the custom tool.
        RandomAccessStreamReference icon =
          RandomAccessStreamReference.CreateFromUri(
            new Uri("ms-appx:///Assets/StoreLogo.png"));

        // Create a menu item for the custom tool.
        RadialControllerMenuItem myItem =
          RadialControllerMenuItem.CreateFromIcon("Sample", icon);

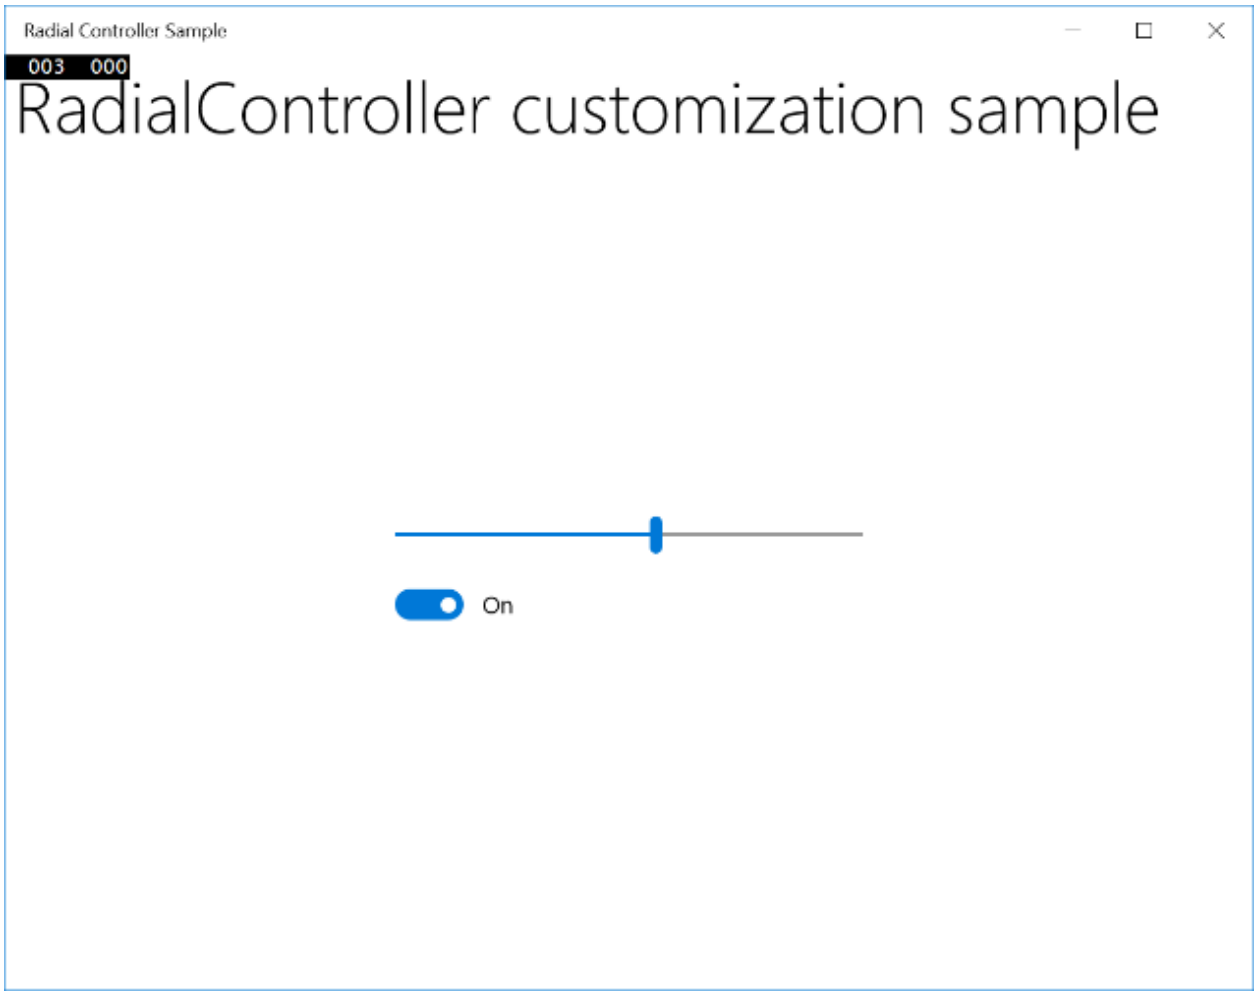
        // Add the custom tool to the RadialController menu.
        myController.Menu.Items.Add(myItem);

        // Declare input handlers for the RadialController.
        myController.ButtonClicked += MyController_ButtonClicked;
        myController.RotationChanged += MyController_RotationChanged;
    }

    // Handler for rotation input from the RadialController.
    private void MyController_RotationChanged(RadialController sender,
      RadialControllerRotationChangedEventArgs args)
    {
        if (RotationSlider.Value + args.RotationDeltaInDegrees > 100)
        {
            RotationSlider.Value = 100;
            return;
        }
        else if (RotationSlider.Value + args.RotationDeltaInDegrees <
0)
        {
            RotationSlider.Value = 0;
            return;
        }
        RotationSlider.Value += args.RotationDeltaInDegrees;
    }

    // Handler for click input from the RadialController.
    private void MyController_ButtonClicked(RadialController sender,
      RadialControllerButtonClickedEventArgs args)
    {
        ButtonToggle.IsOn = !ButtonToggle.IsOn;
    }
}
```

When we run the app, we use the Surface Dial to interact with it. First, we press and hold to open the menu and select our custom tool. Once the custom tool is activated, the slider control can be adjusted by rotating the Dial and the switch can be toggled by clicking the Dial.



The sample app UI activated using the Surface Dial custom tool

Specify the built-in tools

You can use the **RadialControllerConfiguration** class to customize the collection of built-in menu items for your app.

For example, if your app doesn't have any scrolling or zooming regions and doesn't require undo/redo functionality, these tools can be removed from the menu. This opens space on the menu to add custom tools for your app.

> **ⓘ Important**
>
> The Surface Dial menu must have at least one menu item. If all default tools are removed before you add one of your custom tools, the default tools are restored and your tool is appended to the default collection.

Per the design guidelines, we do not recommend removing the media control tools (volume and previous/next track) as users often have background music playing while they perform other tasks.

Here, we show how to configure the Surface Dial menu to include only media controls for volume and next/previous track.

```C#
public MainPage()
{
  ...
  //Remove a subset of the default system tools
  RadialControllerConfiguration myConfiguration =
  RadialControllerConfiguration.GetForCurrentView();
  myConfiguration.SetDefaultMenuItems(new[]
  {
    RadialControllerSystemMenuItemKind.Volume,
      RadialControllerSystemMenuItemKind.NextPreviousTrack
  });
}
```

Custom interactions

As mentioned, the Surface Dial supports three gestures (press and hold, rotate, click) with corresponding default interactions.

Ensure any custom interactions based on these gestures make sense for the selected action or tool.

> ⓘ **Note**
>
> The interaction experience is dependent on the state of the Surface Dial menu. If the menu is active, it processes the input; otherwise, your app does.

Press and hold

This gesture activates and shows the Surface Dial menu, there is no app functionality associated with this gesture.

By default, the menu is displayed at the center of the user's screen. However, the user can grab it and move it anywhere they choose.

> ⓘ **Note**
>
> When the Surface Dial is placed on the screen of the Surface Studio, the menu is centered at the on-screen location of the Surface Dial.

Rotate

The Surface Dial is primarily designed to support rotation for interactions that involve smooth, incremental adjustments to analog values or controls.

The device can be rotated both clockwise and counter-clockwise, and can also provide haptic feedback to indicate discrete distances.

> ⓘ **Note**
>
> Haptic feedback can be disabled by the user in the **Windows Settings -> Devices -> Wheel** page.

UX guidance for custom interactions

Tools with continuous or high rotational sensitivity should disable haptic feedback

Haptic feedback matches the rotational sensitivity of the active tool. We recommend disabling haptic feedback for tools with continuous or high rotational sensitivity as the user experience can get uncomfortable.

Dominant hand should not affect rotation-based interactions

The Surface Dial cannot detect which hand is being used, but the user can set the writing (or dominant hand) in **Windows Settings -> Device -> Pen & Windows Ink**.

Locale should be considered for all rotation interactions

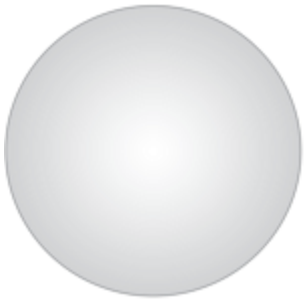
Maximize customer satisfaction by accomodating and adapting your interactions to locale and right-to-left layouts.

The built-in tools and commands on the Dial menu follow these guidelines for rotation-based interactions:

Left

Up

Out



Right

Down

In

Conceptual direction	Mapping to Surface Dial	Clockwise rotation	Counter-clockwise rotation
Horizontal	Left and right mapping based on the top of the Surface Dial	Right	Left
Vertical	Up and down mapping based on the left side of the Surface Dial	Down	Up
Z-axis	In (or nearer) mapped to up/right Out (or further) mapped to down/left	In	Out

Developer guidance

As the user rotates the device, RadialController.RotationChanged events are fired based on a delta (RadialControllerRotationChangedEventArgs.RotationDeltaInDegrees) relative to the direction of rotation. The sensitivity (or resolution) of the data can be set with the RadialController.RotationResolutionInDegrees property.

> **Note**
>
> By default, a rotational input event is delivered to a RadialController object only when the device is rotated a minimum of 10 degrees. Each input event causes the device to vibrate.

In general, we recommend disabling haptic feedback when the rotation resolution is set to less than 5 degrees. This provides a smoother experience for continuous interactions.

You can enable and disable haptic feedback for custom tools by setting the RadialController.UseAutomaticHapticFeedback property.

> **Note**
>
> You cannot override the haptic behavior for system tools such as the volume control. For these tools, haptic feedback can be disabled only by the user from the wheel settings page.

Here's an example of how to customize the resolution of the rotation data and enable or disable haptic feedback.

C#

```
private void MyController_ButtonClicked(RadialController sender,
  RadialControllerButtonClickedEventArgs args)
{
  ButtonToggle.IsOn = !ButtonToggle.IsOn;

  if(ButtonToggle.IsOn)
  {
    //high resolution mode
    RotationSlider.LargeChange = 1;
    myController.UseAutomaticHapticFeedback = false;
    myController.RotationResolutionInDegrees = 1;
  }
  else
  {
    //low resolution mode
    RotationSlider.LargeChange = 10;
    myController.UseAutomaticHapticFeedback = true;
    myController.RotationResolutionInDegrees = 10;
  }
}
```

Click

Clicking the Surface Dial is similar to clicking the left mouse button (the rotation state of the device has no effect on this action).

UX guidance

Do not map an action or command to this gesture if the user cannot easily recover from the result

Any action taken by your app based on the user clicking the Surface Dial must be reversible. Always enable the user to easily traverse the app back stack and restore a previous app state.

Binary operations such as mute/unmute or show/hide provide good user experiences with the click gesture.

Modal tools should not be enabled or disabled by clicking the Surface Dial

Some app/tool modes can conflict with, or disable, interactions that rely on rotation. Tools such as the ruler in the Windows Ink toolbar, should be toggled on or off through other UI affordances (the Ink Toolbar provides a built-in **ToggleButton** control).

For modal tools, map the active Surface Dial menu item to the target tool or to the previously selected menu item.

Developer guidance

When the Surface Dial is clicked, a **RadialController.ButtonClicked** event is fired. The **RadialControllerButtonClickedEventArgs** include a **Contact** property that contains the location and bounding area of the Surface Dial contact on the Surface Studio screen. If the Surface Dial is not in contact with the screen, this property is null.

On-screen

As described earlier, the Surface Dial can be used in conjunction with the Surface Studio to display the Surface Dial menu in a special on-screen mode.

When in this mode, you can integrate and customize your Dial interaction experiences with your apps even further. Examples of unique experiences only possible with the Surface Dial and Surface Studio include:

- Displaying contextual tools (such as a color palette) based on the position of the Surface Dial, which makes them easier to find and use
- Setting the active tool based on the UI the Surface Dial is placed on
- Magnifying a screen area based on location of the Surface Dial
- Unique game interactions based on screen location

UX guidance for on-screen interactions

Apps should respond when the Surface Dial is detected on-screen

Visual feedback helps indicate to users that your app has detected the device on the screen of the Surface Studio.

Adjust Surface Dial-related UI based on device location

The device (and the user's body) can occlude critical UI depending on where the user places it.

Adjust Surface Dial-related UI based on user interaction

In addition to hardware occlusion, a user's hand and arm can occlude part of the screen when using the device.

The occluded area depends on which hand is being used with the device. As the device is designed to be used primarily with the non-dominant hand, Surface Dial-related UI should adjust for the opposite hand specified by the user (**Windows Settings** > **Devices** > **Pen & Windows Ink** > **Choose which hand you write with** setting).

Interactions should respond to Surface Dial position rather than movement

The foot of the device is designed to stick to the screen rather than slide, as it is not a precision pointing device. Therefore, we expect it to be more common for users to lift and place the Surface Dial rather than drag it across the screen.

Use screen position to determine user intent

Setting the active tool based on UI context, such as proximity to a control, canvas, or window, can improve the user experience by reducing the steps required to perform a task.

Developer guidance

When the Surface Dial is placed onto the digitizer surface of the Surface Studio, a **RadialController.ScreenContactStarted** event is fired and the contact info (**RadialControllerScreenContactStartedEventArgs.Contact**) is provided to your app.

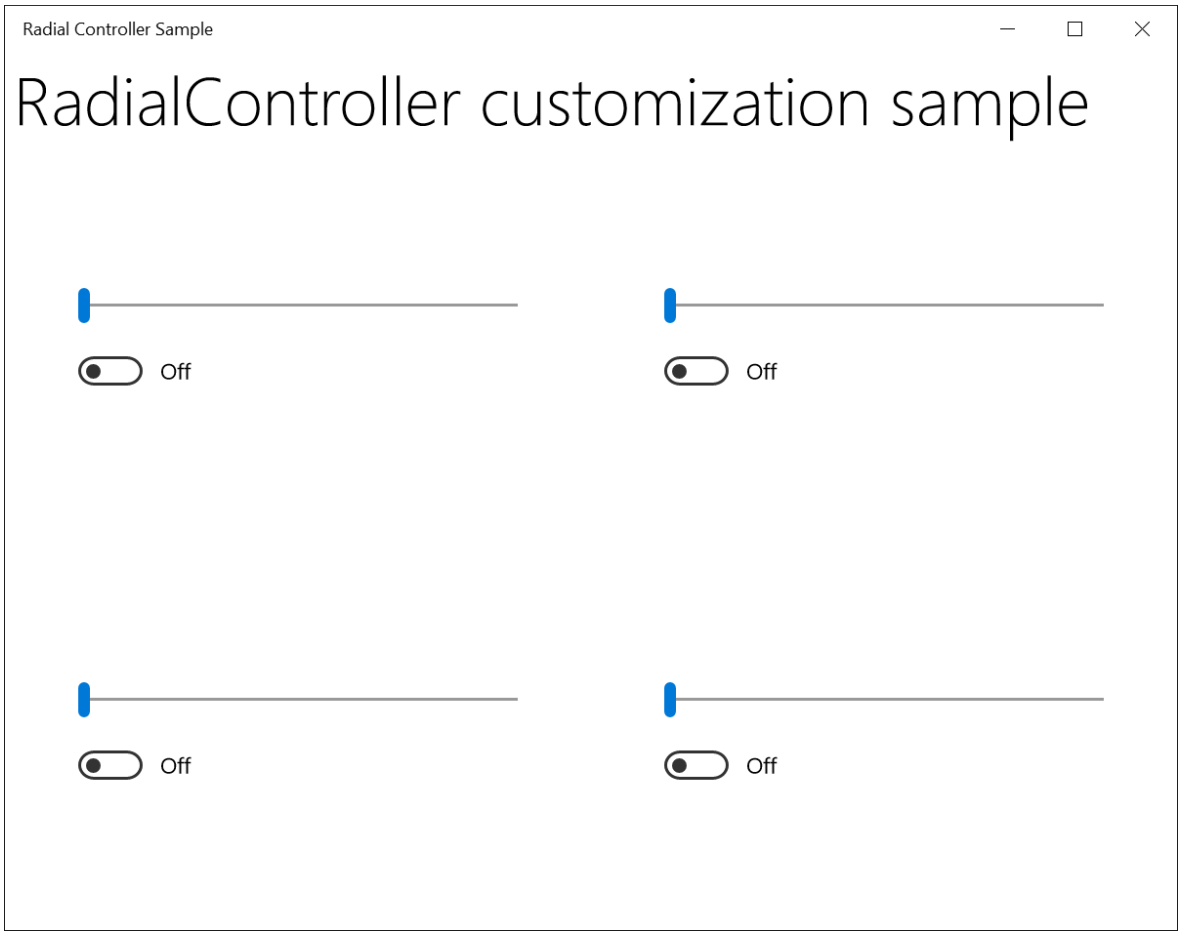
Similarly, if the Surface Dial is clicked when in contact with the digitizer surface of the Surface Studio, a **RadialController.ButtonClicked** event is fired and the contact info (**RadialControllerButtonClickedEventArgs.Contact**) is provided to your app.

The contact info (**RadialControllerScreenContact**) includes the X/Y coordinate of the center of the Surface Dial in the coordinate space of the app (**RadialControllerScreenContact.Position**), as well as the bounding rectangle (**RadialControllerScreenContact.Bounds**) in Device Independent Pixels (DIPs). This info is very useful for providing context to the active tool and providing device-related visual feedback to the user.

In the following example, we've created a basic app with four different sections, each of which includes one slider and one toggle. We then use the onscreen position of the

Surface Dial to dictate which set of sliders and toggles are controlled by the Surface Dial.

1. First, we declare our UI (four sections, each with a slider and toggle button) in XAML.



The sample app UI

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
  <Grid.RowDefinitions>
    <RowDefinition Height="Auto"/>
    <RowDefinition Height="*"/>
  </Grid.RowDefinitions>
  <StackPanel x:Name="HeaderPanel"
        Orientation="Horizontal"
        Grid.Row="0">
    <TextBlock x:Name="Header"
      Text="RadialController customization sample"
      VerticalAlignment="Center"
      Style="{ThemeResource HeaderTextBlockStyle}"
      Margin="10,0,0,0" />
  </StackPanel>
  <Grid Grid.Row="1" x:Name="RootGrid">
    <Grid.RowDefinitions>
      <RowDefinition Height="*"/>
      <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <Grid.ColumnDefinitions>
```

```
      <ColumnDefinition Width="*"/>
      <ColumnDefinition Width="*"/>
    </Grid.ColumnDefinitions>
    <Grid x:Name="Grid0"
      Grid.Row="0"
      Grid.Column="0">
      <StackPanel Orientation="Vertical"
        VerticalAlignment="Center"
        HorizontalAlignment="Center">
        <!-- Slider for rotational input -->
        <Slider x:Name="RotationSlider0"
          Width="300"
          HorizontalAlignment="Left"/>
        <!-- Switch for button input -->
        <ToggleSwitch x:Name="ButtonToggle0"
            HorizontalAlignment="Left"/>
      </StackPanel>
    </Grid>
    <Grid x:Name="Grid1"
      Grid.Row="0"
      Grid.Column="1">
      <StackPanel Orientation="Vertical"
        VerticalAlignment="Center"
        HorizontalAlignment="Center">
        <!-- Slider for rotational input -->
        <Slider x:Name="RotationSlider1"
          Width="300"
          HorizontalAlignment="Left"/>
        <!-- Switch for button input -->
        <ToggleSwitch x:Name="ButtonToggle1"
            HorizontalAlignment="Left"/>
      </StackPanel>
    </Grid>
    <Grid x:Name="Grid2"
      Grid.Row="1"
      Grid.Column="0">
      <StackPanel Orientation="Vertical"
        VerticalAlignment="Center"
        HorizontalAlignment="Center">
        <!-- Slider for rotational input -->
        <Slider x:Name="RotationSlider2"
          Width="300"
          HorizontalAlignment="Left"/>
        <!-- Switch for button input -->
        <ToggleSwitch x:Name="ButtonToggle2"
            HorizontalAlignment="Left"/>
      </StackPanel>
    </Grid>
    <Grid x:Name="Grid3"
      Grid.Row="1"
      Grid.Column="1">
      <StackPanel Orientation="Vertical"
        VerticalAlignment="Center"
        HorizontalAlignment="Center">
        <!-- Slider for rotational input -->
```

```
        <Slider x:Name="RotationSlider3"
          Width="300"
          HorizontalAlignment="Left"/>
        <!-- Switch for button input -->
        <ToggleSwitch x:Name="ButtonToggle3"
            HorizontalAlignment="Left"/>
      </StackPanel>
    </Grid>
  </Grid>
</Grid>
```

2. Here's the code-behind with handlers defined for Surface Dial screen position.

C#

```
Slider ActiveSlider;
ToggleSwitch ActiveSwitch;
Grid ActiveGrid;

public MainPage()
{
  ...

  myController.ScreenContactStarted +=
    MyController_ScreenContactStarted;
  myController.ScreenContactContinued +=
    MyController_ScreenContactContinued;
  myController.ScreenContactEnded +=
    MyController_ScreenContactEnded;
  myController.ControlLost += MyController_ControlLost;

  //Set initial grid for Surface Dial input.
  ActiveGrid = Grid0;
  ActiveSlider = RotationSlider0;
  ActiveSwitch = ButtonToggle0;
}

private void MyController_ScreenContactStarted(RadialController sender,
  RadialControllerScreenContactStartedEventArgs args)
{
  //find grid at contact location, update visuals, selection
  ActivateGridAtLocation(args.Contact.Position);
}

private void MyController_ScreenContactContinued(RadialController
sender,
  RadialControllerScreenContactContinuedEventArgs args)
{
  //if a new grid is under contact location, update visuals, selection
  if (!VisualTreeHelper.FindElementsInHostCoordinates(
    args.Contact.Position, RootGrid).Contains(ActiveGrid))
  {
    ActiveGrid.Background = new
```

```
      SolidColorBrush(Windows.UI.Colors.White);
    ActivateGridAtLocation(args.Contact.Position);
  }
}

private void MyController_ScreenContactEnded(RadialController sender,
object args)
{
  //return grid color to normal when contact leaves screen
  ActiveGrid.Background = new
  SolidColorBrush(Windows.UI.Colors.White);
}

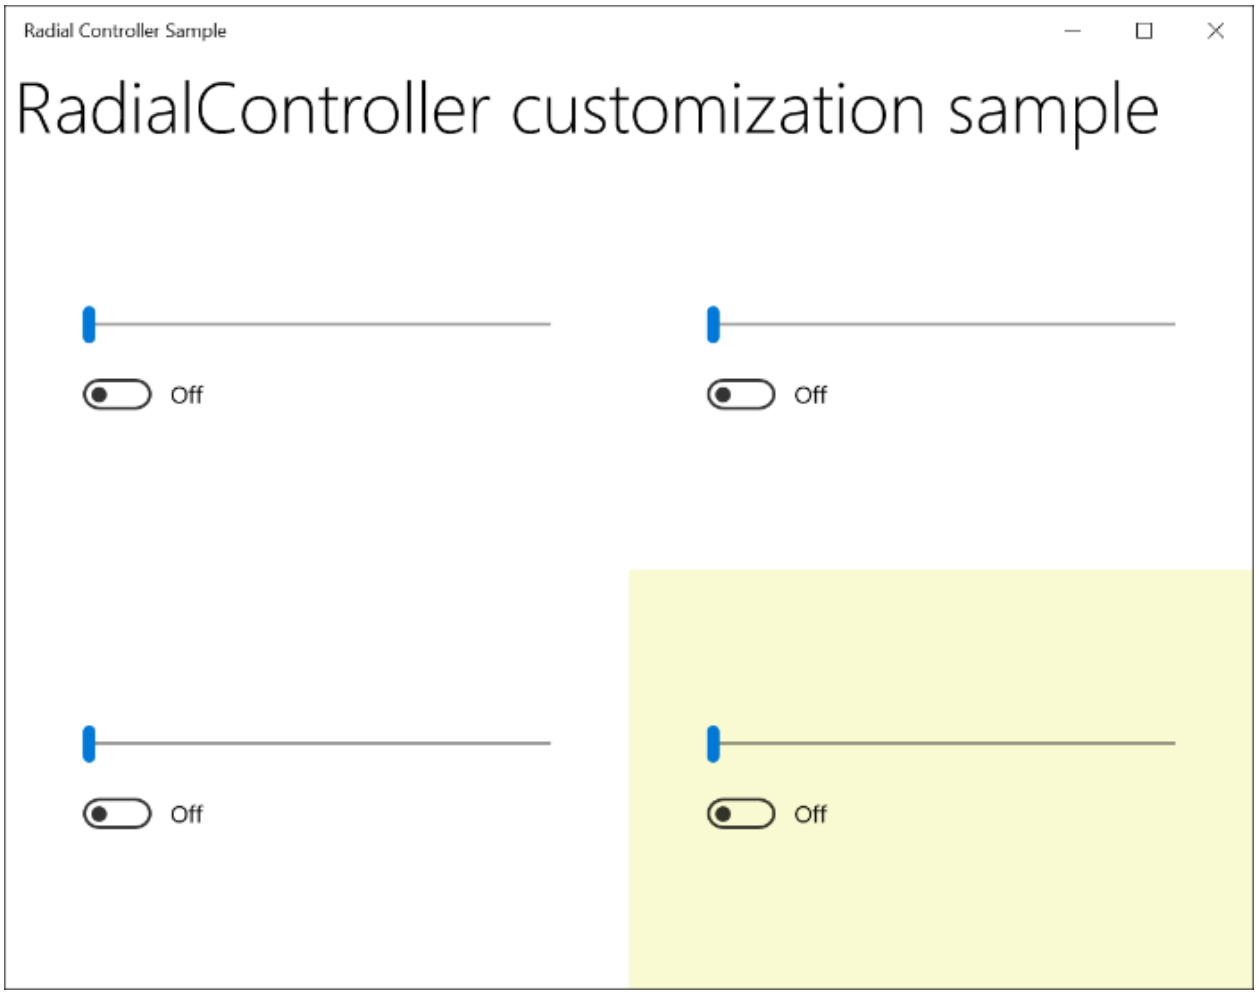
private void MyController_ControlLost(RadialController sender, object
args)
{
  //return grid color to normal when focus lost
  ActiveGrid.Background = new
    SolidColorBrush(Windows.UI.Colors.White);
}

private void ActivateGridAtLocation(Point Location)
{
  var elementsAtContactLocation =
    VisualTreeHelper.FindElementsInHostCoordinates(Location,
      RootGrid);

  foreach (UIElement element in elementsAtContactLocation)
  {
    if (element as Grid == Grid0)
    {
      ActiveSlider = RotationSlider0;
      ActiveSwitch = ButtonToggle0;
      ActiveGrid = Grid0;
      ActiveGrid.Background = new SolidColorBrush(
        Windows.UI.Colors.LightGoldenrodYellow);
      return;
    }
    else if (element as Grid == Grid1)
    {
      ActiveSlider = RotationSlider1;
      ActiveSwitch = ButtonToggle1;
      ActiveGrid = Grid1;
      ActiveGrid.Background = new SolidColorBrush(
        Windows.UI.Colors.LightGoldenrodYellow);
      return;
    }
    else if (element as Grid == Grid2)
    {
      ActiveSlider = RotationSlider2;
      ActiveSwitch = ButtonToggle2;
      ActiveGrid = Grid2;
      ActiveGrid.Background = new SolidColorBrush(
        Windows.UI.Colors.LightGoldenrodYellow);
      return;
```

```
    }
    else if (element as Grid == Grid3)
    {
      ActiveSlider = RotationSlider3;
      ActiveSwitch = ButtonToggle3;
      ActiveGrid = Grid3;
      ActiveGrid.Background = new SolidColorBrush(
        Windows.UI.Colors.LightGoldenrodYellow);
      return;
    }
  }
}
```

When we run the app, we use the Surface Dial to interact with it. First, we place the device on the Surface Studio screen, which the app detects and associates with the lower right section (see image). We then press and hold the Surface Dial to open the menu and select our custom tool. Once the custom tool is activated, the slider control can be adjusted by rotating the Surface Dial and the switch can be toggled by clicking the Surface Dial.



The sample app UI activated using the Surface Dial custom tool

Summary

This topic provides an overview of the Surface Dial input device with UX and developer guidance on how to customize the user experience for off-screen scenarios as well as on-screen scenarios when used with Surface Studio.

Please send your questions, suggestions, and feedback to radialcontroller@microsoft.com.

Tutorial: Support the Surface Dial (and other wheel devices) in your Windows app

Article • 10/06/2022

Surface Dial with Surface Studio and Surface Pen (available for purchase at the Microsoft Store).

This tutorial steps through how to customize the user interaction experiences supported by wheel devices such as the Surface Dial. We use snippets from a sample app, which you can download from GitHub (see Sample code), to demonstrate the various features and associated **RadialController** APIs discussed in each step.

We focus on the following:

- Specifying which built-in tools are displayed on the **RadialController** menu
- Adding a custom tool to the menu
- Controlling haptic feedback
- Customizing click interactions
- Customizing rotation interactions

For more about implementing these and other features, see Surface Dial interactions in Windows apps.

Introduction

The Surface Dial is a secondary input device that helps users to be more productive when used together with a primary input device such as pen, touch, or mouse. As a secondary input device, the Dial is typically used with the non-dominant hand to provide access both to system commands and to other, more contextual, tools and functionality.

The Dial supports three basic gestures:

- Press and hold to display the built-in menu of commands.
- Rotate to highlight a menu item (if the menu is active) or to modify the current action in the app (if the menu is not active).
- Click to select the highlighted menu item (if the menu is active) or to invoke a command in the app (if the menu is not active).

Prerequisites

- A computer (or a virtual machine) running Windows 10 Creators Update or later
- Visual Studio 2019
- Windows 10 SDK (10.0.15063.0)
- A wheel device (only the Surface Dial at this time)
- If you're new to Windows app development with Visual Studio, have a look through these topics before you start this tutorial:
  - Install tools for the Windows App SDK
  - Create a "Hello, world" app (XAML)

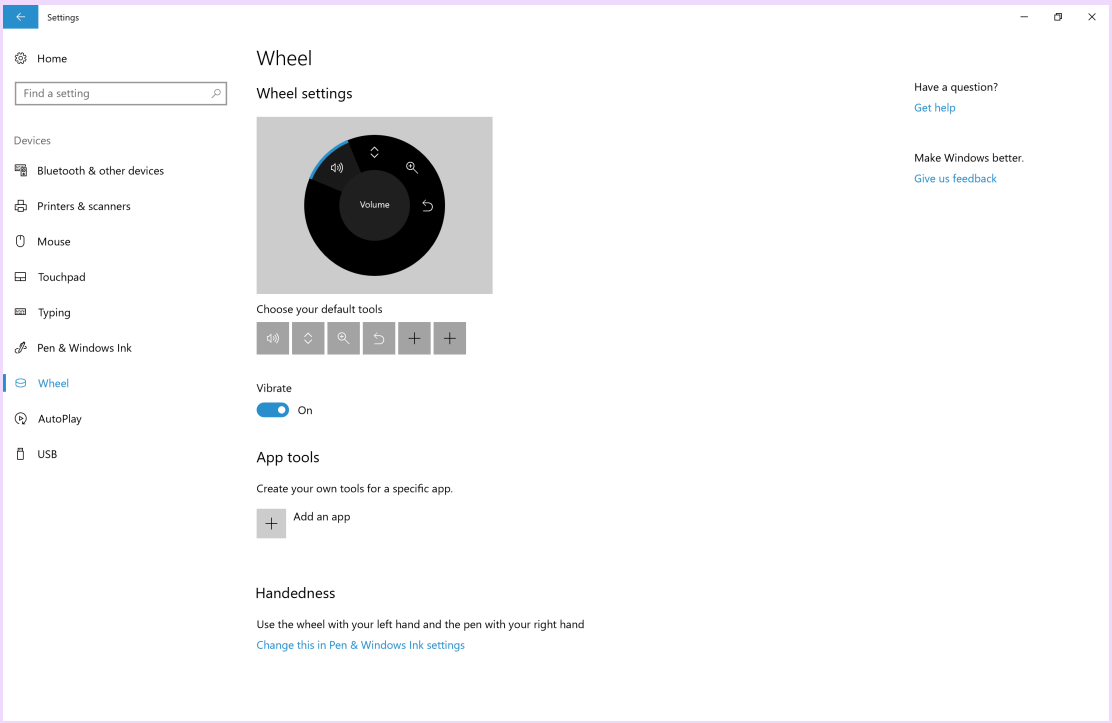
Set up your devices

1. Make sure your Windows device is on.
2. Go to **Start**, select **Settings** > **Devices** > **Bluetooth & other devices**, and then turn **Bluetooth** on.
3. Remove the bottom of the Surface Dial to open the battery compartment, and make sure that there are two AAA batteries inside.
4. If the battery tab is present on the underside of the Dial, remove it.
5. Press and hold the small, inset button next to the batteries until the Bluetooth light flashes.
6. Go back to your Windows device and select **Add Bluetooth or other device**.
7. In the **Add a device** dialog, select **Bluetooth** > **Surface Dial**. Your Surface Dial should now connect and be added to the list of devices under **Mouse, keyboard, & pen** on the **Bluetooth & other devices** settings page.
8. Test the Dial by pressing and holding it down for a few seconds to display the built-in menu.
9. If the menu isn't displayed on your screen (the Dial should also vibrate), go back to the Bluetooth settings, remove the device, and try connecting the device again.

> **Note**

Wheel devices can be configured through the **Wheel** settings:

1. On the **Start** menu, select **Settings**.
2. Select **Devices** > **Wheel**.



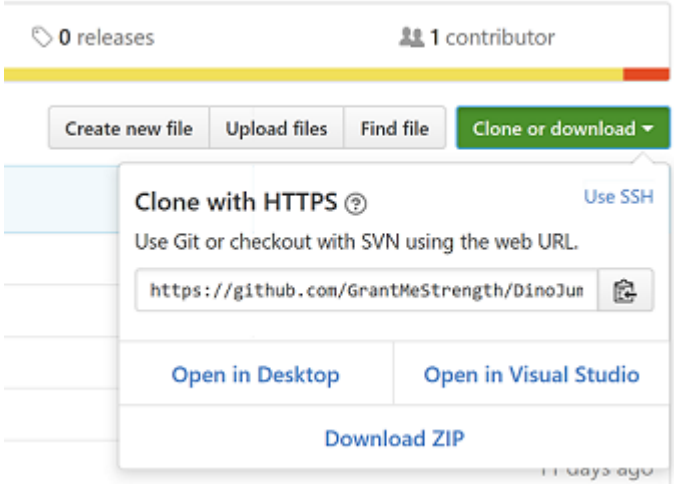
Now you're ready to start this tutorial.

Sample code

Throughout this tutorial, we use a sample app to demonstrate the concepts and functionality discussed.

Download this Visual Studio sample and source code from GitHub at windows-appsample-get-started-radialcontroller sample:

1. Select the green **Clone or download** button.



2. If you have a GitHub account, you can clone the repo to your local machine by choosing **Open in Visual Studio**.
3. If you don't have a GitHub account, or you just want a local copy of the project, choose **Download ZIP** (you'll have to check back regularly to download the latest updates).

> **Important**
>
> Most of the code in the sample is commented out. As we go through each step in this topic, you'll be asked to uncomment various sections of the code. In Visual Studio, just highlight the lines of code, and press CTRL-K and then CTRL-U.

Components that support wheel functionality

These objects provide the bulk of the wheel device experience for Windows apps.

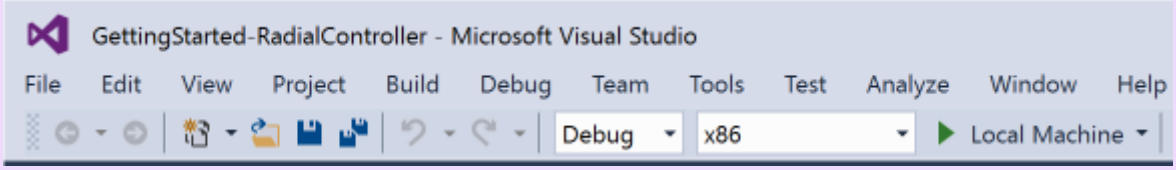
Component	Description
RadialController class and related	Represents a wheel input device or accessory such as the Surface Dial.
IRadialControllerConfigurationInterop / IRadialControllerInterop We do not cover this functionality here, for more information, see the Windows desktop sample.	Enables interoperability with a Windows app.

Step 1: Run the sample

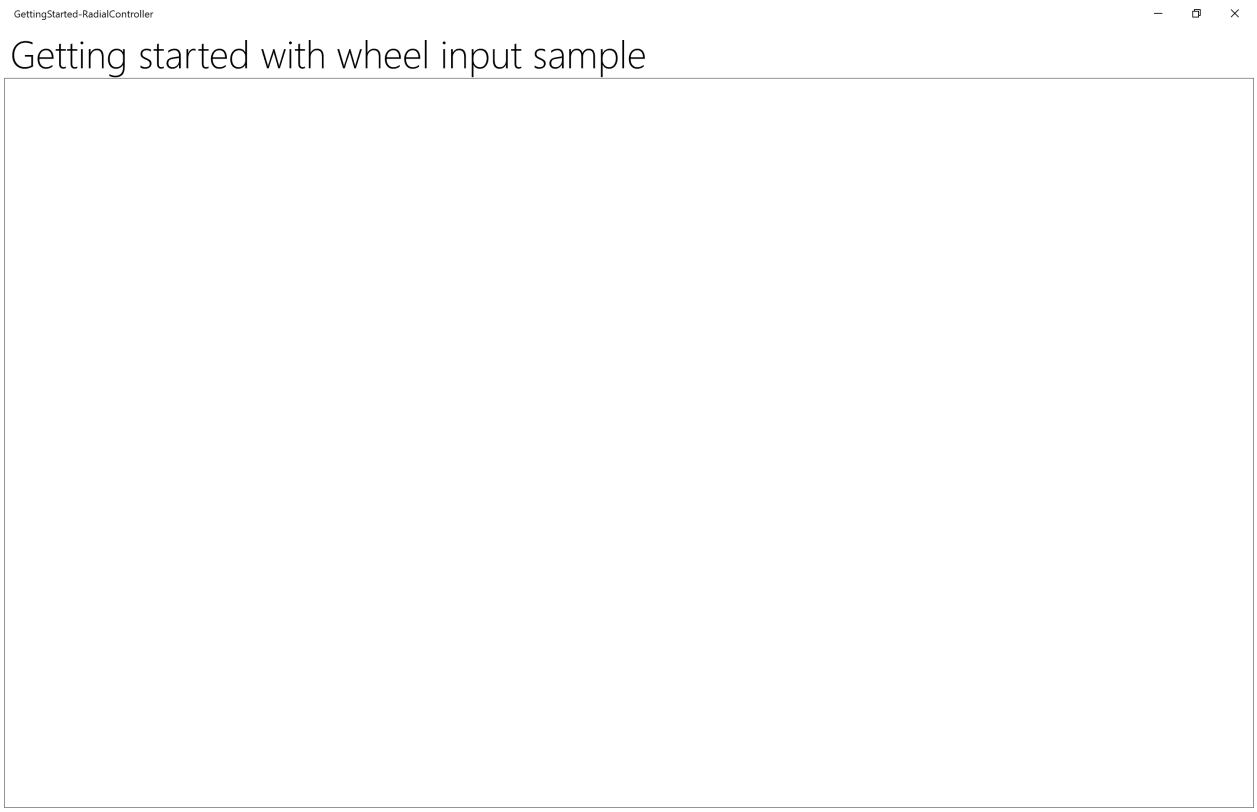
After you've downloaded the RadialController sample app, verify that it runs:

1. Open the sample project in Visual Studio .
2. Set the **Solution Platforms** dropdown to a non-Arm selection.
3. Press F5 to compile, deploy, and run.

> **Note**
>
> Alternatively, you can select **Debug** > **Start debugging** menu item, or select the **Local Machine** Run button shown here:



The app window opens, and after a splash screen appears for a few seconds, you'll see this initial screen.



Okay, we now have the basic Windows app that we'll use throughout the rest of this tutorial. In the following steps, we add our **RadialController** functionality.

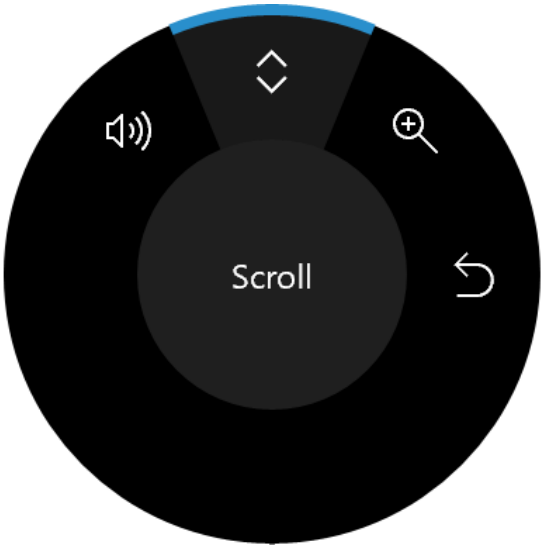
Step 2: Basic RadialController functionality

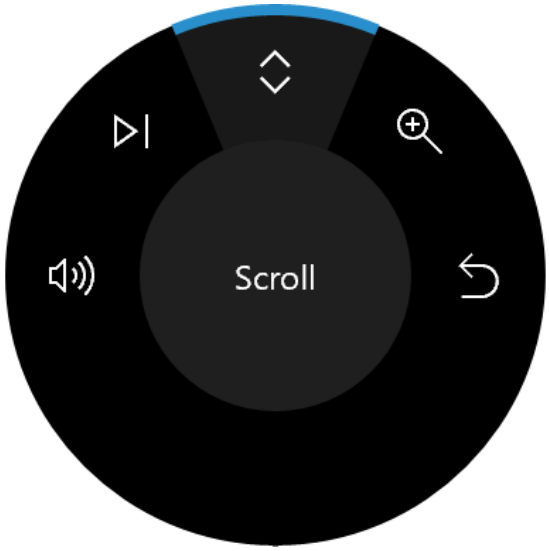
With the app running and in the foreground, press and hold the Surface Dial to display the **RadialController** menu.

We haven't done any customization for our app yet, so the menu contains a default set of contextual tools.

These images show two variations of the default menu. (There are many others, including just basic system tools when the Windows Desktop is active and no apps are in the foreground, additional inking tools when an InkToolbar is present, and mapping tools when you're using the Maps app.

RadialController menu (default)	**RadialController menu (default with media playing)**

RadialController menu (default)	RadialController menu (default with media playing)
	




Now we'll start with some basic customization.

Step 3: Add controls for wheel input

First, let's add the UI for our app:

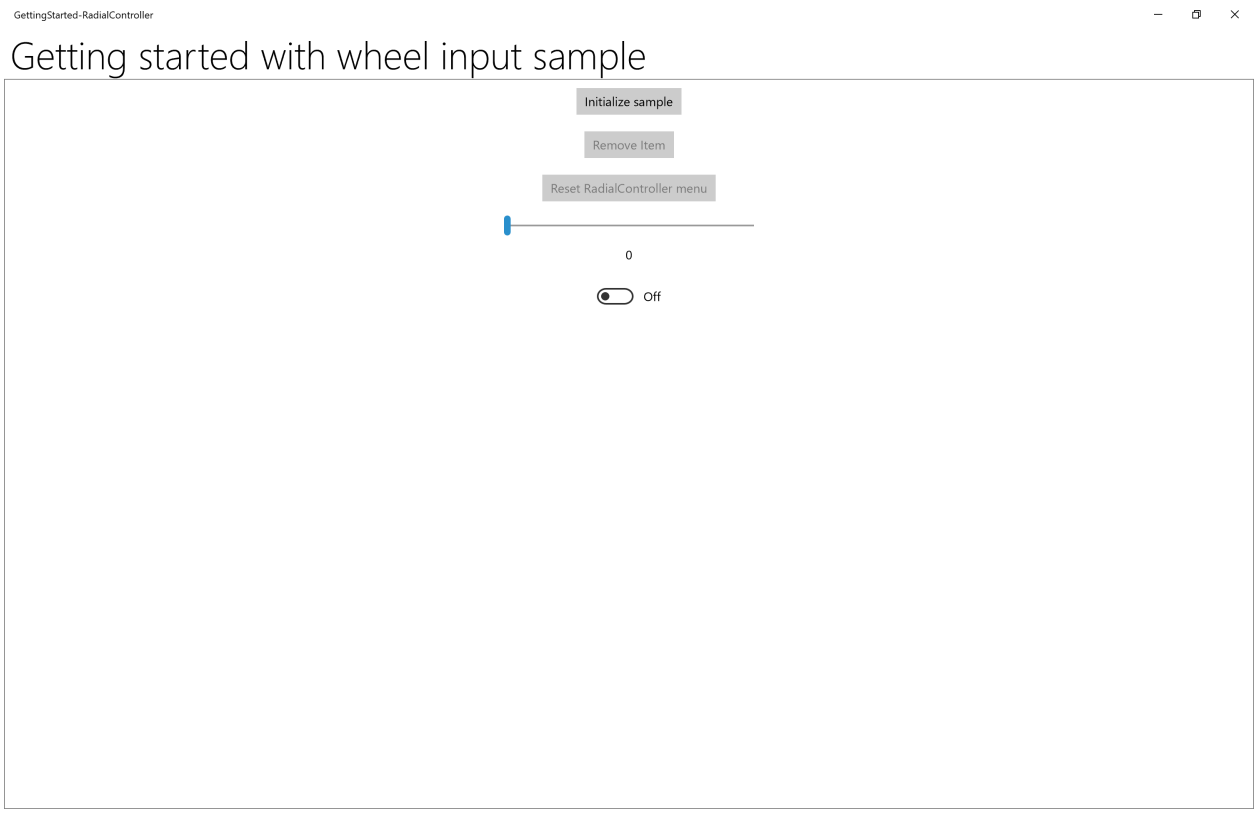
1. Open the MainPage_Basic.xaml file.
2. Find the code marked with the title of this step ("<!-- Step 3: Add controls for wheel input -->").
3. Uncomment the following lines.

XAML

```
<Button x:Name="InitializeSampleButton"
        HorizontalAlignment="Center"
        Margin="10"
        Content="Initialize sample" />
<ToggleButton x:Name="AddRemoveToggleButton"
                HorizontalAlignment="Center"
                Margin="10"
                Content="Remove Item"
                IsChecked="True"
                IsEnabled="False"/>
<Button x:Name="ResetControllerButton"
        HorizontalAlignment="Center"
        Margin="10"
        Content="Reset RadialController menu"
        IsEnabled="False"/>
<Slider x:Name="RotationSlider" Minimum="0" Maximum="10"
        Width="300"
```

```
        HorizontalAlignment="Center"/>
<TextBlock Text="{Binding ElementName=RotationSlider, Mode=OneWay,
Path=Value}"
           Margin="0,0,0,20"
           HorizontalAlignment="Center"/>
<ToggleSwitch x:Name="ClickToggle"
              MinWidth="0"
              Margin="0,0,0,20"
              HorizontalAlignment="center"/>
```

At this point, only the **Initialize sample** button, slider, and toggle switch are enabled. The other buttons are used in later steps to add and remove **RadialController** menu items that provide access to the slider and toggle switch.



Step 4: Customize the basic RadialController menu

Now let's add the code required to enable **RadialController** access to our controls.

1. Open the MainPage_Basic.xaml.cs file.
2. Find the code marked with the title of this step ("// Step 4: Basic RadialController menu customization").
3. Uncomment the following lines:

    - The Windows.UI.Input and Windows.Storage.Streams type references are used for functionality in subsequent steps:

```
C#

// Using directives for RadialController functionality.
using Windows.UI.Input;
```

- These global objects (RadialController, RadialControllerConfiguration, RadialControllerMenuItem) are used throughout our app.

```
C#

private RadialController radialController;
private RadialControllerConfiguration radialControllerConfig;
private RadialControllerMenuItem radialControllerMenuItem;
```

- Here, we specify the **Click** handler for the button that enables our controls and initializes our custom **RadialController** menu item.

```
C#

InitializeSampleButton.Click += (sender, args) =>
{ InitializeSample(sender, args); };
```

- Next, we initialize our RadialController object and set up handlers for the RotationChanged and ButtonClicked events.

```
C#

// Set up the app UI and RadialController.
private void InitializeSample(object sender, RoutedEventArgs e)
{
    ResetControllerButton.IsEnabled = true;
    AddRemoveToggleButton.IsEnabled = true;

    ResetControllerButton.Click += (resetsender, args) =>
    { ResetController(resetsender, args); };
    AddRemoveToggleButton.Click += (togglesender, args) =>
    { AddRemoveItem(togglesender, args); };

    InitializeController(sender, e);
}
```

- Here, we initialize our custom RadialController menu item. We use CreateForCurrentView to get a reference to our RadialController object, we set the rotation sensitivity to "1" by using the RotationResolutionInDegrees property, we then create our RadialControllerMenuItem by using CreateFromFontGlyph, we add the menu item to the **RadialController** menu

item collection, and finally, we use SetDefaultMenuItems to clear the default menu items and leave only our custom tool.

C#

```
// Configure RadialController menu and custom tool.
private void InitializeController(object sender, RoutedEventArgs
args)
{
    // Create a reference to the RadialController.
    radialController = RadialController.CreateForCurrentView();
    // Set rotation resolution to 1 degree of sensitivity.
    radialController.RotationResolutionInDegrees = 1;

    // Create the custom menu items.
    // Here, we use a font glyph for our custom tool.
    radialControllerMenuItem =
        RadialControllerMenuItem.CreateFromFontGlyph("SampleTool",
"\xE1E3", "Segoe MDL2 Assets");

    // Add the item to the RadialController menu.
    radialController.Menu.Items.Add(radialControllerMenuItem);

    // Remove built-in tools to declutter the menu.
    // NOTE: The Surface Dial menu must have at least one menu
item.
    // If all built-in tools are removed before you add a custom
    // tool, the default tools are restored and your tool is
appended
    // to the default collection.
    radialControllerConfig =
        RadialControllerConfiguration.GetForCurrentView();
    radialControllerConfig.SetDefaultMenuItems(
        new RadialControllerSystemMenuItemKind[] { });

    // Declare input handlers for the RadialController.
    // NOTE: These events are only fired when a custom tool is
active.
    radialController.ButtonClicked += (clicksender, clickargs) =>
    { RadialController_ButtonClicked(clicksender, clickargs); };
    radialController.RotationChanged += (rotationsender,
rotationargs) =>
    { RadialController_RotationChanged(rotationsender,
rotationargs); };
}

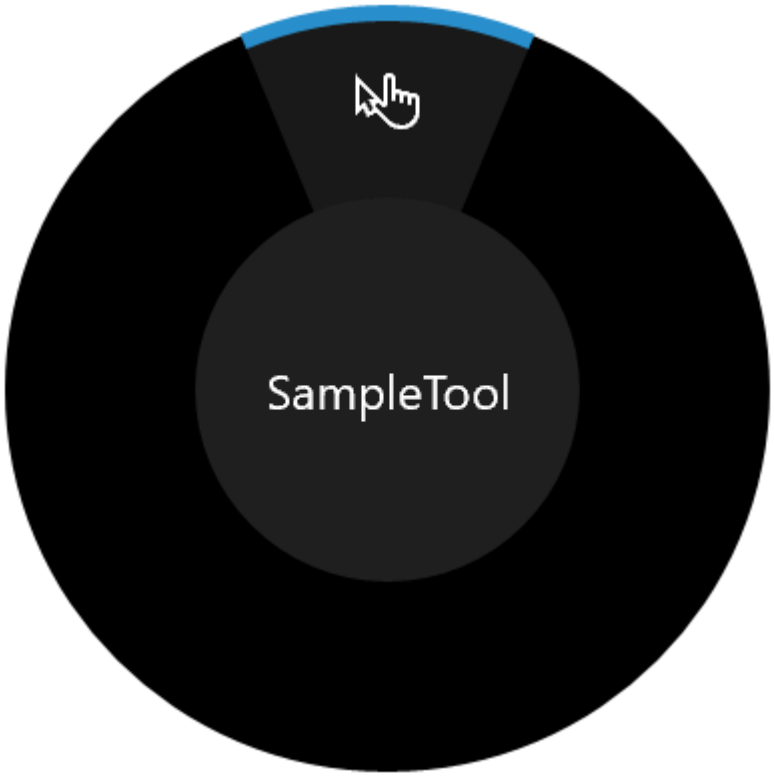
// Connect wheel device rotation to slider control.
private void RadialController_RotationChanged(
    object sender, RadialControllerRotationChangedEventArgs args)
{
    if (RotationSlider.Value + args.RotationDeltaInDegrees >=
RotationSlider.Maximum)
    {
        RotationSlider.Value = RotationSlider.Maximum;
```

```
    }
    else if (RotationSlider.Value + args.RotationDeltaInDegrees <
RotationSlider.Minimum)
    {
        RotationSlider.Value = RotationSlider.Minimum;
    }
    else
    {
        RotationSlider.Value += args.RotationDeltaInDegrees;
    }
}

// Connect wheel device click to toggle switch control.
private void RadialController_ButtonClicked(
    object sender, RadialControllerButtonClickedEventArgs args)
{
    ClickToggle.IsOn = !ClickToggle.IsOn;
}
```

4. Now, run the app again.
5. Select the **Initialize radial controller** button.
6. With the app in the foreground, press and hold the Surface Dial to display the menu. Notice that all default tools have been removed (by using the **RadialControllerConfiguration.SetDefaultMenuItems** method), leaving only the custom tool. Here's the menu with our custom tool.

RadialController menu (custom)



7. Select the custom tool and try out the interactions now supported through the Surface Dial:

    - A rotate action moves the slider.
    - A click sets the toggle to on or off.

Ok, let's hook up those buttons.

Step 5: Configure menu at runtime

In this step, we hook up the **Add/Remove item** and **Reset RadialController menu** buttons to show how you can dynamically customize the menu.

1. Open the MainPage_Basic.xaml.cs file.
2. Find the code marked with the title of this step ("// Step 5: Configure menu at runtime").
3. Uncomment the code in the following methods and run the app again, but don't select any buttons (save that for the next step).

```
C#
```

```
// Add or remove the custom tool.
private void AddRemoveItem(object sender, RoutedEventArgs args)
{
    if (AddRemoveToggleButton?.IsChecked == true)
    {
        AddRemoveToggleButton.Content = "Remove item";
        if
(!radialController.Menu.Items.Contains(radialControllerMenuItem))
        {
            radialController.Menu.Items.Add(radialControllerMenuItem);
        }
    }
    else if (AddRemoveToggleButton?.IsChecked == false)
    {
        AddRemoveToggleButton.Content = "Add item";
        if
(radialController.Menu.Items.Contains(radialControllerMenuItem))
        {

radialController.Menu.Items.Remove(radialControllerMenuItem);
            // Attempts to select and activate the previously selected
tool.
            // NOTE: Does not differentiate between built-in and custom
tools.

radialController.Menu.TrySelectPreviouslySelectedMenuItem();
```

```
        }
    }
}

// Reset the RadialController to initial state.
private void ResetController(object sender, RoutedEventArgs arg)
{
    if
(!radialController.Menu.Items.Contains(radialControllerMenuItem))
    {
        radialController.Menu.Items.Add(radialControllerMenuItem);
    }
    AddRemoveToggleButton.Content = "Remove item";
    AddRemoveToggleButton.IsChecked = true;
    radialControllerConfig.SetDefaultMenuItems(
        new RadialControllerSystemMenuItemKind[] { });
}
```

4. Select the **Remove item** button and then press and hold the Dial to display the menu again.

   Notice that the menu now contains the default collection of tools. Recall that, in Step 3, while setting up our custom menu, we removed all the default tools and added just our custom tool. We also noted that, when the menu is set to an empty collection, the default items for the current context are reinstated. (We added our custom tool before removing the default tools.)

5. Select the **Add item** button and then press and hold the Dial.

   Notice that the menu now contains both the default collection of tools and our custom tool.

6. Select the **Reset RadialController menu** button and then press and hold the Dial.

   Notice that the menu is back to its original state.

Step 6: Customize the device haptics

The Surface Dial, and other wheel devices, can provide users with haptic feedback corresponding to the current interaction (based on either click or rotation).

In this step, we show how you can customize haptic feedback by associating our slider and toggle switch controls and using them to dynamically specify haptic feedback behavior. For this example, the toggle switch must be set to on for feedback to be enabled while the slider value specifies how often the click feedback is repeated.

> **Note**
>
> Haptic feedback can be disabled by the user in the **Settings** > **Devices** > **Wheel** page.

1. Open the App.xaml.cs file.
2. Find the code marked with the title of this step ("Step 6: Customize the device haptics").
3. Comment the first and third lines ("MainPage_Basic" and "MainPage") and uncomment the second ("MainPage_Haptics").

```C#
rootFrame.Navigate(typeof(MainPage_Basic), e.Arguments);
rootFrame.Navigate(typeof(MainPage_Haptics), e.Arguments);
rootFrame.Navigate(typeof(MainPage), e.Arguments);
```

4. Open the MainPage_Haptics.xaml file.
5. Find the code marked with the title of this step ("<!-- Step 6: Customize the device haptics -->").
6. Uncomment the following lines. (This UI code simply indicates what haptics features are supported by the current device.)

```XAML
<StackPanel x:Name="HapticsStack"
            Orientation="Vertical"
            HorizontalAlignment="Center"
            BorderBrush="Gray"
            BorderThickness="1">
    <TextBlock Padding="10"
               Text="Supported haptics properties:" />
    <CheckBox x:Name="CBDefault"
              Content="Default"
              Padding="10"
              IsEnabled="False"
              IsChecked="True" />
    <CheckBox x:Name="CBIntensity"
              Content="Intensity"
              Padding="10"
              IsEnabled="False"
              IsThreeState="True"
              IsChecked="{x:Null}" />
    <CheckBox x:Name="CBPlayCount"
```

```
                Content="Play count"
                Padding="10"
                IsEnabled="False"
                IsThreeState="True"
                IsChecked="{x:Null}" />
    <CheckBox x:Name="CBPlayDuration"
                Content="Play duration"
                Padding="10"
                IsEnabled="False"
                IsThreeState="True"
                IsChecked="{x:Null}" />
    <CheckBox x:Name="CBReplayPauseInterval"
                Content="Replay/pause interval"
                Padding="10"
                IsEnabled="False"
                IsThreeState="True"
                IsChecked="{x:Null}" />
    <CheckBox x:Name="CBBuzzContinuous"
                Content="Buzz continuous"
                Padding="10"
                IsEnabled="False"
                IsThreeState="True"
                IsChecked="{x:Null}" />
    <CheckBox x:Name="CBClick"
                Content="Click"
                Padding="10"
                IsEnabled="False"
                IsThreeState="True"
                IsChecked="{x:Null}" />
    <CheckBox x:Name="CBPress"
                Content="Press"
                Padding="10"
                IsEnabled="False"
                IsThreeState="True"
                IsChecked="{x:Null}" />
    <CheckBox x:Name="CBRelease"
                Content="Release"
                Padding="10"
                IsEnabled="False"
                IsThreeState="True"
                IsChecked="{x:Null}" />
    <CheckBox x:Name="CBRumbleContinuous"
                Content="Rumble continuous"
                Padding="10"
                IsEnabled="False"
                IsThreeState="True"
                IsChecked="{x:Null}" />
</StackPanel>
```

7. Open the MainPage_Haptics.xaml.cs file

8. Find the code marked with the title of this step ("Step 6: Haptics customization")

9. Uncomment the following lines:

- The Windows.Devices.Haptics type reference is used for functionality in subsequent steps.

```
C#

using Windows.Devices.Haptics;
```

- Here, we specify the handler for the ControlAcquired event that is triggered when our custom **RadialController** menu item is selected.

```
C#

radialController.ControlAcquired += (rc_sender, args) =>
{ RadialController_ControlAcquired(rc_sender, args); };
```

- Next, we define the ControlAcquired handler, where we disable default haptic feedback and initialize our haptics UI.

```
C#

private void RadialController_ControlAcquired(
    RadialController rc_sender,
    RadialControllerControlAcquiredEventArgs args)
{
    // Turn off default haptic feedback.
    radialController.UseAutomaticHapticFeedback = false;

    SimpleHapticsController hapticsController =
        args.SimpleHapticsController;

    // Enumerate haptic support.
    IReadOnlyCollection<SimpleHapticsControllerFeedback>
supportedFeedback =
        hapticsController.SupportedFeedback;

    foreach (SimpleHapticsControllerFeedback feedback in
supportedFeedback)
    {
        if (feedback.Waveform ==
KnownSimpleHapticsControllerWaveforms.BuzzContinuous)
        {
            CBBuzzContinuous.IsEnabled = true;
            CBBuzzContinuous.IsChecked = true;
        }
        else if (feedback.Waveform ==
KnownSimpleHapticsControllerWaveforms.Click)
        {
            CBClick.IsEnabled = true;
```

```
            CBClick.IsChecked = true;
        }
        else if (feedback.Waveform ==
KnownSimpleHapticsControllerWaveforms.Press)
        {
            CBPress.IsEnabled = true;
            CBPress.IsChecked = true;
        }
        else if (feedback.Waveform ==
KnownSimpleHapticsControllerWaveforms.Release)
        {
            CBRelease.IsEnabled = true;
            CBRelease.IsChecked = true;
        }
        else if (feedback.Waveform ==
KnownSimpleHapticsControllerWaveforms.RumbleContinuous)
        {
            CBRumbleContinuous.IsEnabled = true;
            CBRumbleContinuous.IsChecked = true;
        }
    }

    if (hapticsController?.IsIntensitySupported == true)
    {
        CBIntensity.IsEnabled = true;
        CBIntensity.IsChecked = true;
    }
    if (hapticsController?.IsPlayCountSupported == true)
    {
        CBPlayCount.IsEnabled = true;
        CBPlayCount.IsChecked = true;
    }
    if (hapticsController?.IsPlayDurationSupported == true)
    {
        CBPlayDuration.IsEnabled = true;
        CBPlayDuration.IsChecked = true;
    }
    if (hapticsController?.IsReplayPauseIntervalSupported == true)
    {
        CBReplayPauseInterval.IsEnabled = true;
        CBReplayPauseInterval.IsChecked = true;
    }
}
```

- In our RotationChanged and ButtonClicked event handlers, we connect the corresponding slider and toggle button controls to our custom haptics.

```
C#

// Connect wheel device rotation to slider control.
private void RadialController_RotationChanged(
    object sender, RadialControllerRotationChangedEventArgs args)
{
```

```
    ...
    if (ClickToggle.IsOn &&
        (RotationSlider.Value > RotationSlider.Minimum) &&
        (RotationSlider.Value < RotationSlider.Maximum))
    {
        SimpleHapticsControllerFeedback waveform =
            FindWaveform(args.SimpleHapticsController,
            KnownSimpleHapticsControllerWaveforms.BuzzContinuous);
        if (waveform != null)
        {

args.SimpleHapticsController.SendHapticFeedback(waveform);
        }
    }
}

private void RadialController_ButtonClicked(
    object sender, RadialControllerButtonClickedEventArgs args)
{
    ...

    if (RotationSlider?.Value > 0)
    {
        SimpleHapticsControllerFeedback waveform =
            FindWaveform(args.SimpleHapticsController,
            KnownSimpleHapticsControllerWaveforms.Click);

        if (waveform != null)
        {

args.SimpleHapticsController.SendHapticFeedbackForPlayCount(
                waveform, 1.0,
                (int)RotationSlider.Value,
                TimeSpan.Parse("1"));
        }
    }
}
```

- Finally, we get the requested **Waveform** (if supported) for the haptic feedback.

C#

```
// Get the requested waveform.
private SimpleHapticsControllerFeedback FindWaveform(
    SimpleHapticsController hapticsController,
    ushort waveform)
{
    foreach (var hapticInfo in
hapticsController.SupportedFeedback)
    {
        if (hapticInfo.Waveform == waveform)
        {
```

```
                return hapticInfo;
            }
        }
        return null;
    }
```

Now run the app again to try out the custom haptics by changing the slider value and toggle-switch state.

Step 7: Define on-screen interactions for Surface Studio and similar devices

Paired with the Surface Studio, the Surface Dial can provide an even more distinctive user experience.

In addition to the default press and hold menu experience described, the Surface Dial can also be placed directly on the screen of the Surface Studio. This enables a special "on-screen" menu.

By detecting both the contact location and bounds of the Surface Dial, the system handles occlusion by the device and displays a larger version of the menu that wraps around the outside of the Dial. This same info can also be used by your app to adapt the UI for both the presence of the device and its anticipated usage, such as the placement of the user's hand and arm.

The sample that accompanies this tutorial includes a slightly more complex example that demonstrates some of these capabilities.

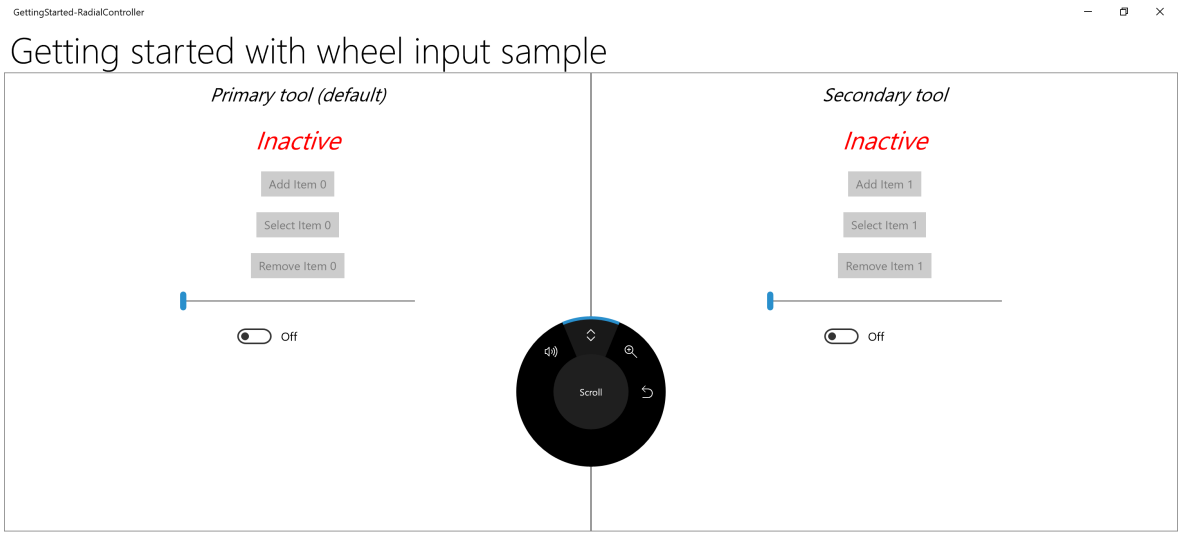
To see this in action (you'll need a Surface Studio):

1. Download the sample on a Surface Studio device (with Visual Studio installed)
2. Open the sample in Visual Studio
3. Open the App.xaml.cs file
4. Find the code marked with the title of this step ("Step 7: Define on-screen interactions for Surface Studio and similar devices")
5. Comment the first and second lines ("MainPage_Basic" and "MainPage_Haptics") and uncomment the third ("MainPage")

```
C#
```

```
rootFrame.Navigate(typeof(MainPage_Basic), e.Arguments);
rootFrame.Navigate(typeof(MainPage_Haptics), e.Arguments);
rootFrame.Navigate(typeof(MainPage), e.Arguments);
```

6. Run the app and place the Surface Dial in each of the two control regions, alternating between them.



Summary

Congratulations, you've completed the *Get Started Tutorial: Support the Surface Dial (and other wheel devices) in your Windows app*! We showed you the basic code required for supporting a wheel device in your Windows apps, and how to provide some of the richer user experiences supported by the **RadialController** APIs.

Speech interactions

Article • 06/24/2021

Integrate speech recognition and text-to-speech (also known as TTS, or speech synthesis) directly into the user experience of your app.

Speech recognition Speech recognition converts words spoken by the user into text for form input, for text dictation, to specify an action or command, and to accomplish tasks. Both pre-defined grammars for free-text dictation and web search, and custom grammars authored using Speech Recognition Grammar Specification (SRGS) Version 1.0 are supported.

TTS TTS uses a speech synthesis engine (voice) to convert a text string into spoken words. The input string can be either basic, unadorned text or more complex Speech Synthesis Markup Language (SSML). SSML provides a standard way to control characteristics of speech output, such as pronunciation, volume, pitch, rate or speed, and emphasis.

Other speech-related components: Cortana in Windows applications uses customized voice commands (spoken or typed) to launch your app to the foreground (the app takes focus, just as if it was launched from the Start menu) or activate as a background service (**Cortana** retains focus but provides results from the app). See Cortana interactions in Windows apps.

Speech interaction design

Designed and implemented thoughtfully, speech can be a robust and enjoyable way for people to interact with your app, complementing, or even replacing, keyboard, mouse, touch, and gestures.

These guidelines and recommendations describe how to best integrate both speech recognition and TTS into the interaction experience of your app.

If you are considering supporting speech interactions in your app:

- What actions can be taken through speech? Can a user navigate between pages, invoke commands, or enter data as text fields, brief notes, or long messages?
- Is speech input a good option for completing a task?
- How does a user know when speech input is available?
- Is the app always listening, or does the user need to take an action for the app to enter listening mode?

- What phrases initiate an action or behavior? Do the phrases and actions need to be enumerated on screen?
- Are prompt, confirmation, and disambiguation screens or TTS required?
- What is the interaction dialog between app and user?
- Is a custom or constrained vocabulary required (such as medicine, science, or locale) for the context of your app?
- Is network connectivity required?

Text input

Speech for text input can range from short form (single word or phrase) to long form (continuous dictation). Short form input must be less than 10 seconds in length, while long form input session can be up to two minutes in length. (Long form input can be restarted without user intervention to give the impression of continuous dictation.)

You should provide a visual cue to indicate that speech recognition is supported and available to the user and whether the user needs to turn it on. For example, a command bar button with a microphone glyph (see Command bars) can be used to show both availability and state.

Provide ongoing recognition feedback to minimize any apparent lack of response while recognition is being performed.

Let users revise recognition text using keyboard input, disambiguation prompts, suggestions, or additional speech recognition.

Stop recognition if input is detected from a device other than speech recognition, such as touch or keyboard. This probably indicates that the user has moved onto another task, such as correcting the recognition text or interacting with other form fields.

Specify the length of time for which no speech input indicates that recognition is over. Do not automatically restart recognition after this period of time as it typically indicates the user has stopped engaging with your app.

Disable all continuous recognition UI and terminate the recognition session if a network connection is not available. Continuous recognition requires a network connection.

Commanding

Speech input can initiate actions, invoke commands, and accomplish tasks.

If space permits, consider displaying the supported responses for the current app context, with examples of valid input. This reduces the potential responses your app has to process and also eliminates confusion for the user.

Try to frame your questions such that they elicit as specific a response as possible. For example, "What do you want to do today?" is very open ended and would require a very large grammar definition due to how varied the responses could be. Alternatively, "Would you like to play a game or listen to music?" constrains the response to one of two valid answers with a correspondingly small grammar definition. A small grammar is much easier to author and results in much more accurate recognition results.

Request confirmation from the user when speech recognition confidence is low. If the user's intent is unclear, it's better to get clarification than to initiate an unintended action.

You should provide a visual cue to indicate that speech recognition is supported and available to the user and whether the user needs to turn it on. For example, a command bar button with a microphone glyph (see Guidelines for command bars) can be used to show both availability and state.

If the speech recognition switch is typically out of view, consider displaying a state indicator in the content area of the app.

If recognition is initiated by the user, consider using the built-in recognition experience for consistency. The built-in experience includes customizable screens with prompts, examples, disambiguations, confirmations, and errors.

The screens vary depending on the specified constraints:

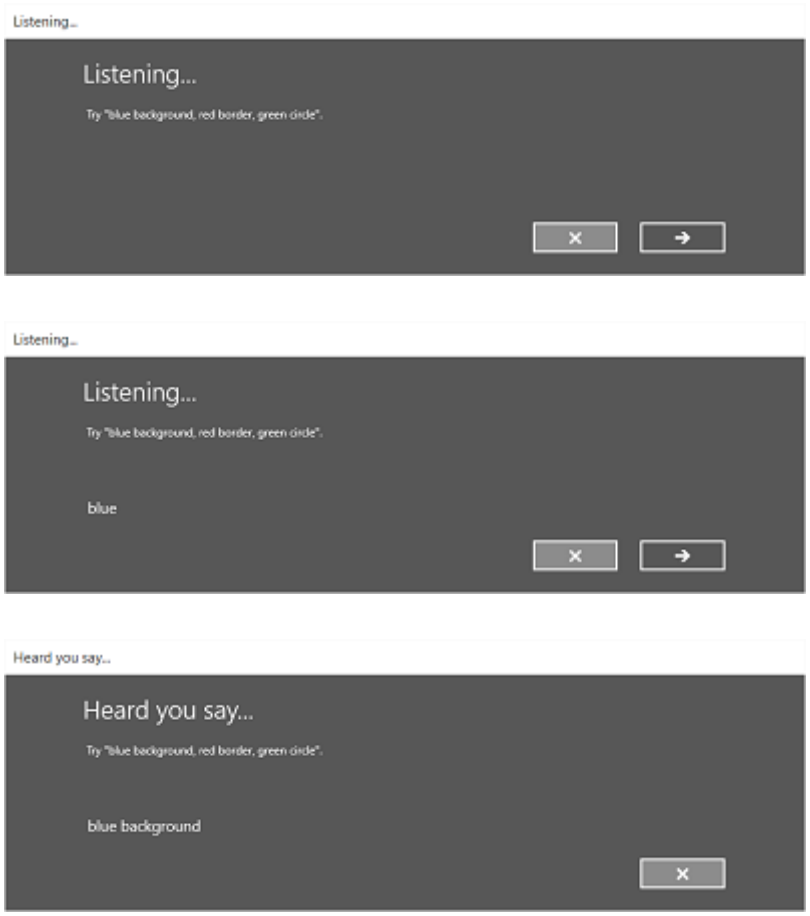
- Pre-defined grammar (dictation or web search)
  - The **Listening** screen.
  - The **Thinking** screen.
  - The **Heard you say** screen or the error screen.
- List of words or phrases, or a SRGS grammar file
  - The **Listening** screen.
  - The **Did you say** screen, if what the user said could be interpreted as more than one potential result.
  - The **Heard you say** screen or the error screen.

On the **Listening** screen you can:

- Customize the heading text.
- Provide example text of what the user can say.

- Specify whether the **Heard you say** screen is shown.
- Read the recognized string back to the user on the **Heard you say** screen.

Here is an example of the built-in recognition flow for a speech recognizer that uses a SRGS-defined constraint. In this example, speech recognition is successful.



Always listening

Your app can listen for and recognize speech input as soon as the app is launched, without user intervention.

You should customize the grammar constraints based on the app context. This keeps the speech recognition experience very targeted and relevant to the current task, and minimizes errors.

"What can I say?"

When speech input is enabled, it's important to help users discover what exactly can be understood and what actions can be performed.

If speech recognition is user enabled, consider using the command bar or a menu command to show all words and phrases supported in the current context.

If speech recognition is always on, consider adding the phrase "What can I say?" to every page. When the user says this phrase, display all words and phrases supported in the current context. Using this phrase provides a consistent way for users to discover speech capabilities across the system.

Recognition failures

Speech recognition will fail. Failures happen when audio quality is poor, when only part of a phrase is recognized, or when no input is detected at all.

Handle failure gracefully, help a user understand why recognition failed, and recover.

Your app should inform the user that they weren't understood and that they need to try again.

Consider providing examples of one or more supported phrases. The user is likely to repeat a suggested phrase, which increases recognition success.

You should display a list of potential matches for a user to select from. This can be far more efficient than going through the recognition process again.

You should always support alternative input types, which is especially helpful for handling repeated recognition failures. For example, you could suggest that the user try to use a keyboard, or use touch or a mouse to select from a list of potential matches.

Use the built-in speech recognition experience as it includes screens that inform the user that recognition was not successful and lets the user make another recognition attempt.

Listen for and try to correct issues in the audio input. The speech recognizer can detect issues with the audio quality that might adversely affect speech recognition accuracy. You can use the information provided by the speech recognizer to inform the user of the issue and let them take corrective action, if possible. For example, if the volume setting on the microphone is too low, you can prompt the user to speak louder or turn the volume up.

Constraints

Constraints, or grammars, define the spoken words and phrases that can be matched by the speech recognizer. You can specify one of the pre-defined web service grammars or you can create a custom grammar that is installed with your app.

Predefined grammars

Predefined dictation and web-search grammars provide speech recognition for your app without requiring you to author a grammar. When using these grammars, speech recognition is performed by a remote web service and the results are returned to the device

- The default free-text dictation grammar can recognize most words and phrases that a user can say in a particular language, and is optimized to recognize short phrases. Free-text dictation is useful when you don't want to limit the kinds of things a user can say. Typical uses include creating notes or dictating the content for a message.
- The web-search grammar, like a dictation grammar, contains a large number of words and phrases that a user might say. However, it is optimized to recognize terms that people typically use when searching the web.

> **Note**
>
> Because predefined dictation and web-search grammars can be large, and because they are online (not on the device), performance might not be as fast as with a custom grammar installed on the device.

These predefined grammars can be used to recognize up to 10 seconds of speech input and require no authoring effort on your part. However, they do require connection to a network.

Custom grammars

A custom grammar is designed and authored by you and is installed with your app. Speech recognition using a custom constraint is performed on the device.

- Programmatic list constraints provide a lightweight approach to creating simple grammars using a list of words or phrases. A list constraint works well for recognizing short, distinct phrases. Explicitly specifying all words in a grammar also improves recognition accuracy, as the speech recognition engine must only process speech to confirm a match. The list can also be programmatically updated.

- An SRGS grammar is a static document that, unlike a programmatic list constraint, uses the XML format defined by the SRGS Version 1.0. An SRGS grammar provides the greatest control over the speech recognition experience by letting you capture multiple semantic meanings in a single recognition.

Here are some tips for authoring SRGS grammars:

- Keep each grammar small. Grammars that contain fewer phrases tend to provide more accurate recognition than larger grammars that contain many phrases. It's better to have several smaller grammars for specific scenarios than to have a single grammar for your entire app.
- Let users know what to say for each app context and enable and disable grammars as needed.
- Design each grammar so users can speak a command in a variety of ways. For example, you can use the **GARBAGE** rule to match speech input that your grammar does not define. This lets users speak additional words that have no meaning to your app. For example, "give me", "and", "uh", "maybe", and so on.
- Use the sapi:subset element to help match speech input. This is a Microsoft extension to the SRGS specification to help match partial phrases.
- Try to avoid defining phrases in your grammar that contain only one syllable. Recognition tends to be more accurate for phrases containing two or more syllables.
- Avoid using phrases that sound similar. For example, phrases such as "hello", "bellow", and "fellow" can confuse the recognition engine and result in poor recognition accuracy.

> **Note**
>
> Which type of constraint type you use depends on the complexity of the recognition experience you want to create. Any could be the best choice for a specific recognition task, and you might find uses for all types of constraints in your app.

Custom pronunciations

If your app contains specialized vocabulary with unusual or fictional words, or words with uncommon pronunciations, you might be able to improve recognition performance for those words by defining custom pronunciations.

For a small list of words and phrases, or a list of infrequently used words and phrases, you can create custom pronunciations in a SRGS grammar. See token Element for more info.

For larger lists of words and phrases, or frequently used words and phrases, you can create separate pronunciation lexicon documents. See About Lexicons and Phonetic Alphabets for more info.

Testing

Test speech recognition accuracy and any supporting UI with your app's target audience. This is the best way to determine the effectiveness of the speech interaction experience in your app. For example, are users getting poor recognition results because your app isn't listening for a common phrase?

Either modify the grammar to support this phrase or provide users with a list of supported phrases. If you already provide the list of supported phrases, ensure it is easily discoverable.

Text-to-speech (TTS)

TTS generates speech output from plain text or SSML.

Try to design prompts that are polite and encouraging.

Consider whether you should read long strings of text. It's one thing to listen to a text message, but quite another to listen to a long list of search results that are difficult to remember.

You should provide media controls to let users pause, or stop, TTS.

You should listen to all TTS strings to ensure they are intelligible and sound natural.

- Stringing together an unusual sequence of words or speaking part numbers or punctuation might cause a phrase to become unintelligible.
- Speech can sound unnatural when the prosody or cadence is different from how a native speaker would say a phrase.

Both issues can be addressed by using SSML instead of plain text as input to the speech synthesizer. For more info about SSML, see Use SSML to Control Synthesized Speech and Speech Synthesis Markup Language Reference.

Speech recognition

Article • 06/24/2021

Use speech recognition to provide input, specify an action or command, and accomplish tasks.

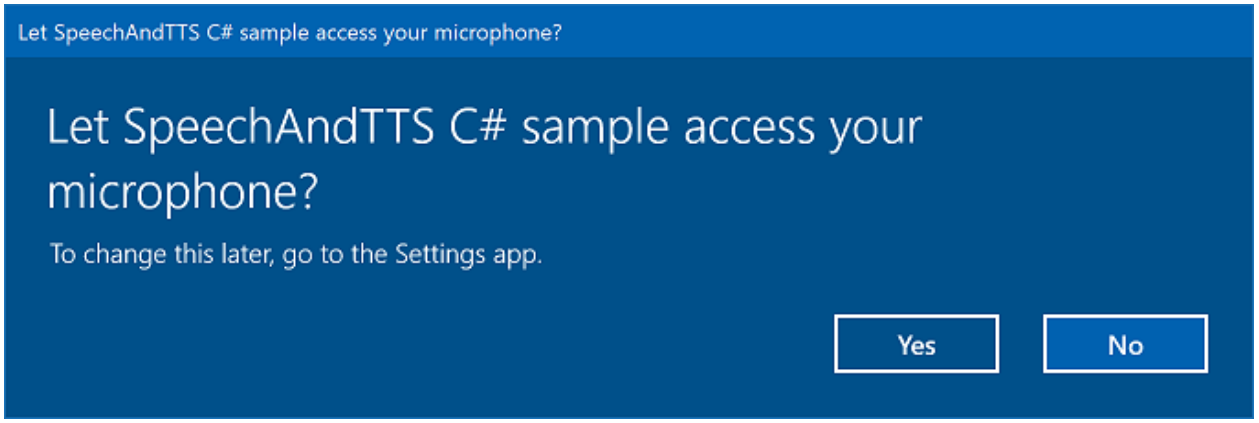
> **Important APIs**: Windows.Media.SpeechRecognition

Speech recognition is made up of a speech runtime, recognition APIs for programming the runtime, ready-to-use grammars for dictation and web search, and a default system UI that helps users discover and use speech recognition features.

Configure speech recognition

To support speech recognition with your app, the user must connect and enable a microphone on their device, and accept the Microsoft Privacy Policy granting permission for your app to use it.

To automatically prompt the user with a system dialog requesting permission to access and use the microphone's audio feed (example from the Speech recognition and speech synthesis sample shown below), just set the **Microphone** device capability in the App package manifest. For more detail, see App capability declarations.



If the user clicks Yes to grant access to the microphone, your app is added to the list of approved applications on the Settings -> Privacy -> Microphone page. However, as the user can choose to turn this setting off at any time, you should confirm that your app has access to the microphone before attempting to use it.

If you also want to support dictation, Cortana, or other speech recognition services (such as a predefined grammar defined in a topic constraint), you must also confirm that **Online speech recognition** (Settings -> Privacy -> Speech) is enabled.

This snippet shows how your app can check if a microphone is present and if it has permission to use it.

C#

```
public class AudioCapturePermissions
{
    // If no microphone is present, an exception is thrown with the
following HResult value.
    private static int NoCaptureDevicesHResult = -1072845856;

    /// <summary>
    /// Note that this method only checks the Settings->Privacy->Microphone
setting, it does not handle
    /// the Cortana/Dictation privacy check.
    ///
    /// You should perform this check every time the app gets focus, in case
the user has changed
    /// the setting while the app was suspended or not in focus.
    /// </summary>
    /// <returns>True, if the microphone is available.</returns>
    public async static Task<bool> RequestMicrophonePermission()
    {
        try
        {
            // Request access to the audio capture device.
            MediaCaptureInitializationSettings settings = new
MediaCaptureInitializationSettings();
            settings.StreamingCaptureMode = StreamingCaptureMode.Audio;
            settings.MediaCategory = MediaCategory.Speech;
            MediaCapture capture = new MediaCapture();

            await capture.InitializeAsync(settings);
        }
        catch (TypeLoadException)
        {
            // Thrown when a media player is not available.
            var messageDialog = new Windows.UI.Popups.MessageDialog("Media
player components are unavailable.");
            await messageDialog.ShowAsync();
            return false;
        }
        catch (UnauthorizedAccessException)
        {
            // Thrown when permission to use the audio capture device is
denied.
            // If this occurs, show an error or disable recognition
functionality.
            return false;
        }
        catch (Exception exception)
        {
            // Thrown when an audio capture device is not present.
            if (exception.HResult == NoCaptureDevicesHResult)
```

```
            {
                var messageDialog = new Windows.UI.Popups.MessageDialog("No
Audio Capture devices are present on this system.");
                await messageDialog.ShowAsync();
                return false;
            }
            else
            {
                throw;
            }
        }
        return true;
    }
}
```

C++

```
/// <summary>
/// Note that this method only checks the Settings->Privacy->Microphone
setting, it does not handle
/// the Cortana/Dictation privacy check.
///
/// You should perform this check every time the app gets focus, in case the
user has changed
/// the setting while the app was suspended or not in focus.
/// </summary>
/// <returns>True, if the microphone is available.</returns>

            /// </summary>
            /// <returns>True, if the microphone is available.</returns>
            return new WinJS.Promise(function (completed, error) {

                try {
                    // Request access to the audio capture device.
                    var captureSettings = new
```

```
Windows.Media.Capture.MediaCaptureInitializationSettings();
                    captureSettings.streamingCaptureMode =
Windows.Media.Capture.StreamingCaptureMode.audio;
                    captureSettings.mediaCategory =
Windows.Media.Capture.MediaCategory.speech;

                    var capture = new Windows.Media.Capture.MediaCapture();
                    capture.initializeAsync(captureSettings).then(function
() {
                        completed(true);
                    },
                    function (error) {
                        // Audio Capture can fail to initialize if there's
no audio devices on the system, or if
                        // the user has disabled permission to access the
microphone in the Privacy settings.
                        if (error.number == -2147024891) { // Access denied
(microphone disabled in settings)
                            completed(false);
                        } else if (error.number == -1072845856) { // No
recording device present.
                            var messageDialog = new
Windows.UI.Popups.MessageDialog("No Audio Capture devices are present on
this system.");
                            messageDialog.showAsync();
                            completed(false);
                        } else {
                            error(error);
                        }
                    });
                } catch (exception) {
                    if (exception.number == -2147221164) { //
REGDB_E_CLASSNOTREG
                        var messageDialog = new
Windows.UI.Popups.MessageDialog("Media Player components not available on
this system.");
                        messageDialog.showAsync();
                        return false;
                    }
                }
            });
        }
    })
```

Recognize speech input

A *constraint* defines the words and phrases (vocabulary) that an app recognizes in speech input. Constraints are at the core of speech recognition and give your app greater control over the accuracy of speech recognition.

You can use the following types of constraints for recognizing speech input.

Predefined grammars

Predefined dictation and web-search grammars provide speech recognition for your app without requiring you to author a grammar. When using these grammars, speech recognition is performed by a remote web service and the results are returned to the device.

The default free-text dictation grammar can recognize most words and phrases that a user can say in a particular language, and is optimized to recognize short phrases. The predefined dictation grammar is used if you don't specify any constraints for your SpeechRecognizer object. Free-text dictation is useful when you don't want to limit the kinds of things a user can say. Typical uses include creating notes or dictating the content for a message.

The web-search grammar, like a dictation grammar, contains a large number of words and phrases that a user might say. However, it is optimized to recognize terms that people typically use when searching the web.

> ⓘ **Note**
>
> Because predefined dictation and web-search grammars can be large, and because they are online (not on the device), performance might not be as fast as with a custom grammar installed on the device.

These predefined grammars can be used to recognize up to 10 seconds of speech input and require no authoring effort on your part. However, they do require a connection to a network.

To use web-service constraints, speech input and dictation support must be enabled in **Settings** by turning on the "Get to know me" option in **Settings -> Privacy -> Speech, inking, and typing**.

Here, we show how to test whether speech input is enabled and open the Settings -> Privacy -> Speech, inking, and typing page, if not.

First, we initialize a global variable (HResultPrivacyStatementDeclined) to the HResult value of 0x80045509. See Exception handling for in C# or Visual Basic.

C#

```
private static uint HResultPrivacyStatementDeclined = 0x80045509;
```

We then catch any standard exceptions during recognition and test if the HResult value is equal to the value of the HResultPrivacyStatementDeclined variable. If so, we display a warning and call `await Windows.System.Launcher.LaunchUriAsync(new Uri("ms-settings:privacy-accounts"));` to open the Settings page.

```
C#

catch (Exception exception)
{
  // Handle the speech privacy policy error.
  if ((uint)exception.HResult == HResultPrivacyStatementDeclined)
  {
    resultTextBlock.Visibility = Visibility.Visible;
    resultTextBlock.Text = "The privacy statement was declined." +
      "Go to Settings -> Privacy -> Speech, inking and typing, and ensure
you" +
      "have viewed the privacy policy, and 'Get To Know You' is enabled.";
    // Open the privacy/speech, inking, and typing settings page.
    await Windows.System.Launcher.LaunchUriAsync(new Uri("ms-
settings:privacy-accounts"));
  }
  else
  {
    var messageDialog = new
Windows.UI.Popups.MessageDialog(exception.Message, "Exception");
    await messageDialog.ShowAsync();
  }
}
```

See SpeechRecognitionTopicConstraint.

Programmatic list constraints

Programmatic list constraints provide a lightweight approach to creating simple grammars using a list of words or phrases. A list constraint works well for recognizing short, distinct phrases. Explicitly specifying all words in a grammar also improves recognition accuracy, as the speech recognition engine must only process speech to confirm a match. The list can also be programmatically updated.

A list constraint consists of an array of strings that represents speech input that your app will accept for a recognition operation. You can create a list constraint in your app by creating a speech-recognition list-constraint object and passing an array of strings. Then, add that object to the constraints collection of the recognizer. Recognition is successful when the speech recognizer recognizes any one of the strings in the array.

See SpeechRecognitionListConstraint.

SRGS grammars

An Speech Recognition Grammar Specification (SRGS) grammar is a static document that, unlike a programmatic list constraint, uses the XML format defined by the SRGS Version 1.0. An SRGS grammar provides the greatest control over the speech recognition experience by letting you capture multiple semantic meanings in a single recognition.

See **SpeechRecognitionGrammarFileConstraint**.

Voice command constraints

Use a Voice Command Definition (VCD) XML file to define the commands that the user can say to initiate actions when activating your app. For more detail, see Activate a foreground app with voice commands through Cortana.

See **SpeechRecognitionVoiceCommandDefinitionConstraint**/

Note The type of constraint type you use depends on the complexity of the recognition experience you want to create. Any could be the best choice for a specific recognition task, and you might find uses for all types of constraints in your app. To get started with constraints, see Define custom recognition constraints.

The predefined Universal Windows app dictation grammar recognizes most words and short phrases in a language. It is activated by default when a speech recognizer object is instantiated without custom constraints.

In this example, we show how to:

- Create a speech recognizer.
- Compile the default Universal Windows app constraints (no grammars have been added to the speech recognizer's grammar set).
- Start listening for speech by using the basic recognition UI and TTS feedback provided by the **RecognizeWithUIAsync** method. Use the **RecognizeAsync** method if the default UI is not required.

CSharp

```
private async void StartRecognizing_Click(object sender, RoutedEventArgs e)
{
    // Create an instance of SpeechRecognizer.
    var speechRecognizer = new
Windows.Media.SpeechRecognition.SpeechRecognizer();

    // Compile the dictation grammar by default.
```

```
    await speechRecognizer.CompileConstraintsAsync();

    // Start recognition.
    Windows.Media.SpeechRecognition.SpeechRecognitionResult
speechRecognitionResult = await speechRecognizer.RecognizeWithUIAsync();

    // Do something with the recognition result.
    var messageDialog = new
Windows.UI.Popups.MessageDialog(speechRecognitionResult.Text, "Text
spoken");
    await messageDialog.ShowAsync();
}
```

Customize the recognition UI

When your app attempts speech recognition by calling SpeechRecognizer.RecognizeWithUIAsync, several screens are shown in the following order.

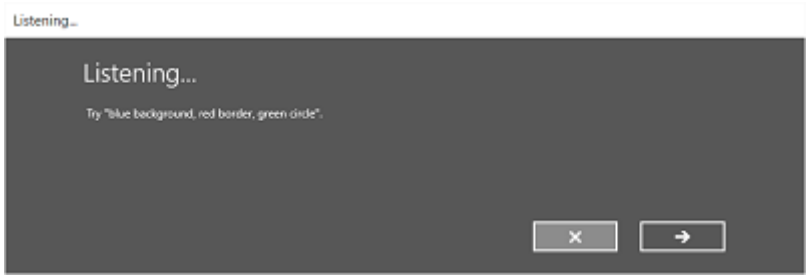
If you're using a constraint based on a predefined grammar (dictation or web search):

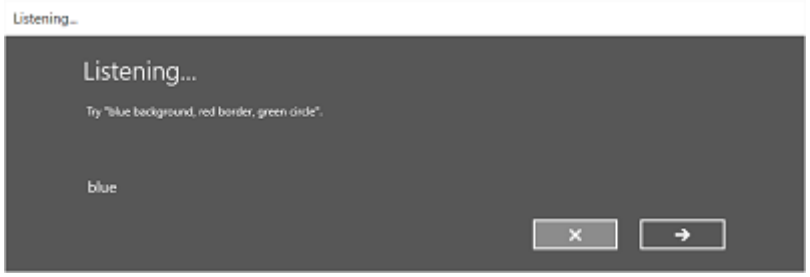
- The **Listening** screen.
- The **Thinking** screen.
- The **Heard you say** screen or the error screen.

If you're using a constraint based on a list of words or phrases, or a constraint based on a SRGS grammar file:

- The **Listening** screen.
- The **Did you say** screen, if what the user said could be interpreted as more than one potential result.
- The **Heard you say** screen or the error screen.

The following image shows an example of the flow between screens for a speech recognizer that uses a constraint based on a SRGS grammar file. In this example, speech recognition was successful.





The **Listening** screen can provide examples of words or phrases that the app can recognize. Here, we show how to use the properties of the SpeechRecognizerUIOptions class (obtained by calling the SpeechRecognizer.UIOptions property) to customize content on the **Listening** screen.

CSharp

```
private async void WeatherSearch_Click(object sender, RoutedEventArgs e)
{
    // Create an instance of SpeechRecognizer.
    var speechRecognizer = new
Windows.Media.SpeechRecognition.SpeechRecognizer();

    // Listen for audio input issues.
    speechRecognizer.RecognitionQualityDegrading +=
speechRecognizer_RecognitionQualityDegrading;

    // Add a web search grammar to the recognizer.
    var webSearchGrammar = new
Windows.Media.SpeechRecognition.SpeechRecognitionTopicConstraint(Windows.Med
ia.SpeechRecognition.SpeechRecognitionScenario.WebSearch, "webSearch");

    speechRecognizer.UIOptions.AudiblePrompt = "Say what you want to search
for...";
    speechRecognizer.UIOptions.ExampleText = @"Ex. 'weather for London'";
    speechRecognizer.Constraints.Add(webSearchGrammar);

    // Compile the constraint.
    await speechRecognizer.CompileConstraintsAsync();

    // Start recognition.
    Windows.Media.SpeechRecognition.SpeechRecognitionResult
speechRecognitionResult = await speechRecognizer.RecognizeWithUIAsync();
    //await speechRecognizer.RecognizeWithUIAsync();
```

```
    // Do something with the recognition result.
    var messageDialog = new
Windows.UI.Popups.MessageDialog(speechRecognitionResult.Text, "Text
spoken");
    await messageDialog.ShowAsync();
}
```

Specify the speech recognizer language

Article • 06/24/2021

Learn how to select an installed language to use for speech recognition.

> **Important APIs**: SupportedTopicLanguages, SupportedGrammarLanguages, Language

Here, we enumerate the languages installed on a system, identify which is the default language, and select a different language for recognition.

Prerequisites:

This topic builds on Speech recognition.

You should have a basic understanding of speech recognition and recognition constraints.

If you're new to developing Windows apps, have a look through these topics to get familiar with the technologies discussed here.

- Create your first app
- Learn about events with Events and routed events overview

User experience guidelines:

For helpful tips about designing a useful and engaging speech-enabled app, see Speech design guidelines .

Identify the default language

A speech recognizer uses the system speech language as its default recognition language. This language is set by the user on the device Settings > System > Speech > Speech Language screen.

We identify the default language by checking the **SystemSpeechLanguage** static property.

CSharp

```
var language = SpeechRecognizer.SystemSpeechLanguage;
```

Confirm an installed language

Installed languages can vary between devices. You should verify the existence of a language if you depend on it for a particular constraint.

Note A reboot is required after a new language pack is installed. An exception with error code SPERR_NOT_FOUND (0x8004503a) is raised if the specified language is not supported or has not finished installing.

Determine the supported languages on a device by checking one of two static properties of the SpeechRecognizer class:

- SupportedTopicLanguages—The collection of Language objects used with predefined dictation and web search grammars.
- SupportedGrammarLanguages—The collection of Language objects used with a list constraint or a Speech Recognition Grammar Specification (SRGS) file.

Specify a language

To specify a language, pass a Language object in the SpeechRecognizer constructor.

Here, we specify "en-US" as the recognition language.

CSharp

```
var language = new Windows.Globalization.Language("en-US");
var recognizer = new SpeechRecognizer(language);
```

Remarks

A topic constraint can be configured by adding a SpeechRecognitionTopicConstraint to the Constraints collection of the SpeechRecognizer and then calling CompileConstraintsAsync. A SpeechRecognitionResultStatus of **TopicLanguageNotSupported** is returned if the recognizer is not initialized with a supported topic language.

A list constraint is configured by adding a SpeechRecognitionListConstraint to the Constraints collection of the SpeechRecognizer and then calling CompileConstraintsAsync. You cannot specify the language of a custom list directly. Instead, the list will be processed using the language of the recognizer.

An SRGS grammar is an open-standard XML format represented by the **SpeechRecognitionGrammarFileConstraint** class. Unlike custom lists, you can specify the language of the grammar in the SRGS markup. **CompileConstraintsAsync** fails with a **SpeechRecognitionResultStatus** of **TopicLanguageNotSupported** if the recognizer is not initialized to the same language as the SRGS markup.

Define custom recognition constraints

Article • 06/24/2021

Learn how to define and use custom constraints for speech recognition.

> **Important APIs**: SpeechRecognitionTopicConstraint, SpeechRecognitionListConstraint, SpeechRecognitionGrammarFileConstraint

Speech recognition requires at least one constraint to define a recognizable vocabulary. If no constraint is specified, the predefined dictation grammar of Universal Windows apps is used. See Speech recognition.

Add constraints

Use the SpeechRecognizer.Constraints property to add constraints to a speech recognizer.

Here, we cover the three kinds of speech recognition constraints used from within an app. (For Cortana voice command constraints, see Activate a foreground app with voice commands through Cortana.)

- SpeechRecognitionTopicConstraint—A constraint based on a predefined grammar (dictation or web search).
- SpeechRecognitionListConstraint—A constraint based on a list of words or phrases.
- SpeechRecognitionGrammarFileConstraint—A constraint defined in a Speech Recognition Grammar Specification (SRGS) file.

Each speech recognizer can have one constraint collection. Only these combinations of constraints are valid:

- A single-topic constraint (dictation or web search)
- For Windows 10 Fall Creators Update (10.0.16299.15) and newer, a single topic constraint can be combined with a list constraint
- A combination of list constraints and/or grammar-file constraints.

> **ⓘ Important**
>
> Call the SpeechRecognizer.CompileConstraintsAsync method to compile the constraints before starting the recognition process.

Specify a web-search grammar (SpeechRecognitionTopicConstraint)

Topic constraints (dictation or web-search grammar) must be added to the constraints collection of a speech recognizer.

> **Note**
>
> You can use a SpeechRecognitionListConstraint in conjunction with a SpeechRecognitionTopicConstraint to increase dictation accuracy by providing a set of domain-specific keywords that you think are likely to be used during dictation.

Here, we add a web-search grammar to the constraints collection.

CSharp

```
private async void WeatherSearch_Click(object sender, RoutedEventArgs e)
{
    // Create an instance of SpeechRecognizer.
    var speechRecognizer = new
Windows.Media.SpeechRecognition.SpeechRecognizer();

    // Listen for audio input issues.
    speechRecognizer.RecognitionQualityDegrading +=
speechRecognizer_RecognitionQualityDegrading;

    // Add a web search grammar to the recognizer.
    var webSearchGrammar = new
Windows.Media.SpeechRecognition.SpeechRecognitionTopicConstraint(Windows.Med
ia.SpeechRecognition.SpeechRecognitionScenario.WebSearch, "webSearch");

    speechRecognizer.UIOptions.AudiblePrompt = "Say what you want to search
for...";
    speechRecognizer.UIOptions.ExampleText = @"Ex. 'weather for London'";
    speechRecognizer.Constraints.Add(webSearchGrammar);

    // Compile the constraint.
    await speechRecognizer.CompileConstraintsAsync();

    // Start recognition.
    Windows.Media.SpeechRecognition.SpeechRecognitionResult
speechRecognitionResult = await speechRecognizer.RecognizeWithUIAsync();
    //await speechRecognizer.RecognizeWithUIAsync();

    // Do something with the recognition result.
    var messageDialog = new
```

```
Windows.UI.Popups.MessageDialog(speechRecognitionResult.Text, "Text
spoken");
    await messageDialog.ShowAsync();
}
```

Specify a programmatic list constraint (SpeechRecognitionListConstraint)

List constraints must be added to the constraints collection of a speech recognizer.

Keep the following points in mind:

- You can add multiple list constraints to a constraints collection.
- You can use any collection that implements **IIterable<String>** for the string values.

Here, we programmatically specify an array of words as a list constraint and add it to the constraints collection of a speech recognizer.

CSharp

```
private async void YesOrNo_Click(object sender, RoutedEventArgs e)
{
    // Create an instance of SpeechRecognizer.
    var speechRecognizer = new
Windows.Media.SpeechRecognition.SpeechRecognizer();

    // You could create this array dynamically.
    string[] responses = { "Yes", "No" };

    // Add a list constraint to the recognizer.
    var listConstraint = new
Windows.Media.SpeechRecognition.SpeechRecognitionListConstraint(responses,
"yesOrNo");

    speechRecognizer.UIOptions.ExampleText = @"Ex. 'yes', 'no'";
    speechRecognizer.Constraints.Add(listConstraint);

    // Compile the constraint.
    await speechRecognizer.CompileConstraintsAsync();

    // Start recognition.
    Windows.Media.SpeechRecognition.SpeechRecognitionResult
speechRecognitionResult = await speechRecognizer.RecognizeWithUIAsync();

    // Do something with the recognition result.
    var messageDialog = new
Windows.UI.Popups.MessageDialog(speechRecognitionResult.Text, "Text
spoken");
```

```
    await messageDialog.ShowAsync();
}
```

Specify an SRGS grammar constraint (SpeechRecognitionGrammarFileConstraint)

SRGS grammar files must be added to the constraints collection of a speech recognizer.

The SRGS Version 1.0 is the industry-standard markup language for creating XML-format grammars for speech recognition. Although Universal Windows apps provide alternatives to using SRGS for creating speech-recognition grammars, you might find that using SRGS to create grammars produces the best results, particularly for more involved speech recognition scenarios.

SRGS grammars provide a full set of features to help you architect complex voice interaction for your apps. For example, with SRGS grammars you can:

- Specify the order in which words and phrases must be spoken to be recognized.
- Combine words from multiple lists and phrases to be recognized.
- Link to other grammars.
- Assign a weight to an alternative word or phrase to increase or decrease the likelihood that it will be used to match speech input.
- Include optional words or phrases.
- Use special rules that help filter out unspecified or unanticipated input, such as random speech that doesn't match the grammar, or background noise.
- Use semantics to define what speech recognition means to your app.
- Specify pronunciations, either inline in a grammar or via a link to a lexicon.

For more info about SRGS elements and attributes, see the SRGS Grammar XML Reference . To get started creating an SRGS grammar, see How to Create a Basic XML Grammar.

Keep the following points in mind:

- You can add multiple grammar-file constraints to a constraints collection.
- Use the .grxml file extension for XML-based grammar documents that conform to SRGS rules.

This example uses an SRGS grammar defined in a file named srgs.grxml (described later). In the file properties, the **Package Action** is set to **Content** with **Copy to Output Directory** set to **Copy always**:

```
```

CSharp

```
private async void Colors_Click(object sender, RoutedEventArgs e)
{
    // Create an instance of SpeechRecognizer.
    var speechRecognizer = new
Windows.Media.SpeechRecognition.SpeechRecognizer();

    // Add a grammar file constraint to the recognizer.
    var storageFile = await
Windows.Storage.StorageFile.GetFileFromApplicationUriAsync(new Uri("ms-
appx:///Colors.grxml"));
    var grammarFileConstraint = new
Windows.Media.SpeechRecognition.SpeechRecognitionGrammarFileConstraint(stora
geFile, "colors");

    speechRecognizer.UIOptions.ExampleText = @"Ex. 'blue background', 'green
text'";
    speechRecognizer.Constraints.Add(grammarFileConstraint);

    // Compile the constraint.
    await speechRecognizer.CompileConstraintsAsync();

    // Start recognition.
    Windows.Media.SpeechRecognition.SpeechRecognitionResult
speechRecognitionResult = await speechRecognizer.RecognizeWithUIAsync();

    // Do something with the recognition result.
    var messageDialog = new
Windows.UI.Popups.MessageDialog(speechRecognitionResult.Text, "Text
spoken");
    await messageDialog.ShowAsync();
}
```

This SRGS file (srgs.grxml) includes semantic interpretation tags. These tags provide a mechanism for returning grammar match data to your app. Grammars must conform to the World Wide Web Consortium (W3C) Semantic Interpretation for Speech Recognition (SISR) 1.0 specification.

Here, we listen for variants of "yes" and "no".

CSharp

```
<grammar xml:lang="en-US"
         root="yesOrNo"
         version="1.0"
         tag-format="semantics/1.0"
         xmlns="http://www.w3.org/2001/06/grammar">

    <!-- The following rules recognize variants of yes and no. -->
      <rule id="yesOrNo">
         <one-of>
```

```
            <item>
              <one-of>
                 <item>yes</item>
                 <item>yeah</item>
                 <item>yep</item>
                 <item>yup</item>
                 <item>un huh</item>
                 <item>yay yus</item>
              </one-of>
              <tag>out="yes";</tag>
            </item>
            <item>
              <one-of>
                 <item>no</item>
                 <item>nope</item>
                 <item>nah</item>
                 <item>uh uh</item>
               </one-of>
               <tag>out="no";</tag>
            </item>
         </one-of>
      </rule>
</grammar>
```

Manage constraints

After a constraint collection is loaded for recognition, your app can manage which constraints are enabled for recognition operations by setting the **IsEnabled** property of a constraint to **true** or **false**. The default setting is **true**.

It's usually more efficient to load constraints once, enabling and disabling them as needed, rather than to load, unload, and compile constraints for each recognition operation. Use the **IsEnabled** property, as required.

Restricting the number of constraints serves to limit the amount of data that the speech recognizer needs to search and match against the speech input. This can improve both the performance and the accuracy of speech recognition.

Decide which constraints are enabled based on the phrases that your app can expect in the context of the current recognition operation. For example, if the current app context is to display a color, you probably don't need to enable a constraint that recognizes the names of animals.

To prompt the user for what can be spoken, use the **SpeechRecognizerUIOptions.AudiblePrompt** and **SpeechRecognizerUIOptions.ExampleText** properties, which are set by means of the **SpeechRecognizer.UIOptions** property. Preparing users for what they can say during the

recognition operation increases the likelihood that they will speak a phrase that can be matched to an active constraint.

Continuous dictation

Article • 06/24/2021

Learn how to capture and recognize long-form, continuous dictation speech input.

> **Important APIs**: SpeechContinuousRecognitionSession, ContinuousRecognitionSession

In Speech recognition, you learned how to capture and recognize relatively short speech input using the RecognizeAsync or RecognizeWithUIAsync methods of a SpeechRecognizer object, for example, when composing a short message service (SMS) message or when asking a question.

For longer, continuous speech recognition sessions, such as dictation or email, use the ContinuousRecognitionSession property of a SpeechRecognizer to obtain a SpeechContinuousRecognitionSession object.

> **Note**
>
> Dictation language support depends on the device where your app is running. For PCs and laptops, only en-US is recognized, while Xbox and phones can recognize all languages supported by speech recognition. For more info, see Specify the speech recognizer language.

Set up

Your app needs a few objects to manage a continuous dictation session:

- An instance of a SpeechRecognizer object.
- A reference to a UI dispatcher to update the UI during dictation.
- A way to track the accumulated words spoken by the user.

Here, we declare a SpeechRecognizer instance as a private field of the code-behind class. Your app needs to store a reference elsewhere if you want continuous dictation to persist beyond a single Extensible Application Markup Language (XAML) page.

CSharp

```
private SpeechRecognizer speechRecognizer;
```

During dictation, the recognizer raises events from a background thread. Because a background thread cannot directly update the UI in XAML, your app must use a dispatcher to update the UI in response to recognition events.

Here, we declare a private field that will be initialized later with the UI dispatcher.

CSharp

```
// Speech events may originate from a thread other than the UI thread.
// Keep track of the UI thread dispatcher so that we can update the
// UI in a thread-safe manner.
private CoreDispatcher dispatcher;
```

To track what the user is saying, you need to handle recognition events raised by the speech recognizer. These events provide the recognition results for chunks of user utterances.

Here, we use a **StringBuilder** object to hold all the recognition results obtained during the session. New results are appended to the **StringBuilder** as they are processed.

CSharp

```
private StringBuilder dictatedTextBuilder;
```

Initialization

During the initialization of continuous speech recognition, you must:

- Fetch the dispatcher for the UI thread if you update the UI of your app in the continuous recognition event handlers.
- Initialize the speech recognizer.
- Compile the built-in dictation grammar. **Note** Speech recognition requires at least one constraint to define a recognizable vocabulary. If no constraint is specified, a predefined dictation grammar is used. See Speech recognition.
- Set up the event listeners for recognition events.

In this example, we initialize speech recognition in the **OnNavigatedTo** page event.

1. Because events raised by the speech recognizer occur on a background thread, create a reference to the dispatcher for updates to the UI thread. **OnNavigatedTo** is always invoked on the UI thread.

C#

```
this.dispatcher = CoreWindow.GetForCurrentThread().Dispatcher;
```

2. We then initialize the SpeechRecognizer instance.

```
C#

this.speechRecognizer = new SpeechRecognizer();
```

3. We then add and compile the grammar that defines all of the words and phrases that can be recognized by the SpeechRecognizer.

   If you don't specify a grammar explicitly, a predefined dictation grammar is used by default. Typically, the default grammar is best for general dictation.

   Here, we call CompileConstraintsAsync immediately without adding a grammar.

```
C#

SpeechRecognitionCompilationResult result =
      await speechRecognizer.CompileConstraintsAsync();
```

Handle recognition events

You can capture a single, brief utterance or phrase by calling RecognizeAsync or RecognizeWithUIAsync.

However, to capture a longer, continuous recognition session, we specify event listeners to run in the background as the user speaks and define handlers to build the dictation string.

We then use the ContinuousRecognitionSession property of our recognizer to obtain a SpeechContinuousRecognitionSession object that provides methods and events for managing a continuous recognition session.

Two events in particular are critical:

- ResultGenerated, which occurs when the recognizer has generated some results.
- Completed, which occurs when the continuous recognition session has ended.

The ResultGenerated event is raised as the user speaks. The recognizer continuously listens to the user and periodically raises an event that passes a chunk of speech input. You must examine the speech input, using the Result property of the event argument,

and take appropriate action in the event handler, such as appending the text to a StringBuilder object.

As an instance of SpeechRecognitionResult, the Result property is useful for determining whether you want to accept the speech input. A SpeechRecognitionResult provides two properties for this:

- Status indicates whether the recognition was successful. Recognition can fail for a variety of reasons.
- Confidence indicates the relative confidence that the recognizer understood the correct words.

Here are the basic steps for supporting continuous recognition:

1. Here, we register the handler for the ResultGenerated continuous recognition event in the OnNavigatedTo page event.

C#

```
speechRecognizer.ContinuousRecognitionSession.ResultGenerated +=
        ContinuousRecognitionSession_ResultGenerated;
```

2. We then check the Confidence property. If the value of Confidence is Medium or better, we append the text to the StringBuilder. We also update the UI as we collect input.

   Note the ResultGenerated event is raised on a background thread that cannot update the UI directly. If a handler needs to update the UI (as the [Speech and TTS sample] does), you must dispatch the updates to the UI thread through the RunAsync method of the dispatcher.

C#

```
private async void ContinuousRecognitionSession_ResultGenerated(
      SpeechContinuousRecognitionSession sender,
      SpeechContinuousRecognitionResultGeneratedEventArgs args)
      {

        if (args.Result.Confidence == SpeechRecognitionConfidence.Medium ||
          args.Result.Confidence == SpeechRecognitionConfidence.High)
          {
            dictatedTextBuilder.Append(args.Result.Text + " ");

            await dispatcher.RunAsync(CoreDispatcherPriority.Normal, () =>
            {
              dictationTextBox.Text = dictatedTextBuilder.ToString();
              btnClearText.IsEnabled = true;
```

```
            });
          }
        else
        {
          await dispatcher.RunAsync(CoreDispatcherPriority.Normal, () =>
            {
              dictationTextBox.Text = dictatedTextBuilder.ToString();
            });
        }
      }
```

3. We then handle the **Completed** event, which indicates the end of continuous dictation.

   The session ends when you call the **StopAsync** or **CancelAsync** methods (described the next section). The session can also end when an error occurs, or when the user has stopped speaking. Check the **Status** property of the event argument to determine why the session ended (**SpeechRecognitionResultStatus**).

   Here, we register the handler for the **Completed** continuous recognition event in the **OnNavigatedTo** page event.

```
C#

speechRecognizer.ContinuousRecognitionSession.Completed +=
      ContinuousRecognitionSession_Completed;
```

4. The event handler checks the Status property to determine whether the recognition was successful. It also handles the case where the user has stopped speaking. Often, a **TimeoutExceeded** is considered successful recognition as it means the user has finished speaking. You should handle this case in your code for a good experience.

   Note the **ResultGenerated** event is raised on a background thread that cannot update the UI directly. If a handler needs to update the UI (as the [Speech and TTS sample] does), you must dispatch the updates to the UI thread through the **RunAsync** method of the dispatcher.

```
C#

private async void ContinuousRecognitionSession_Completed(
      SpeechContinuousRecognitionSession sender,
      SpeechContinuousRecognitionCompletedEventArgs args)
      {
        if (args.Status != SpeechRecognitionResultStatus.Success)
        {
          if (args.Status == SpeechRecognitionResultStatus.TimeoutExceeded)
```

```
            {
              await dispatcher.RunAsync(CoreDispatcherPriority.Normal, () =>
              {
                rootPage.NotifyUser(
                  "Automatic Time Out of Dictation",
                  NotifyType.StatusMessage);

                DictationButtonText.Text = " Continuous Recognition";
                dictationTextBox.Text = dictatedTextBuilder.ToString();
              });
            }
            else
            {
              await dispatcher.RunAsync(CoreDispatcherPriority.Normal, () =>
              {
                rootPage.NotifyUser(
                  "Continuous Recognition Completed: " +
args.Status.ToString(),
                  NotifyType.StatusMessage);

                DictationButtonText.Text = " Continuous Recognition";
              });
            }
          }
        }
```

Provide ongoing recognition feedback

When people converse, they often rely on context to fully understand what is being said. Similarly, the speech recognizer often needs context to provide high-confidence recognition results. For example, by themselves, the words "weight" and "wait" are indistinguishable until more context can be gleaned from surrounding words. Until the recognizer has some confidence that a word, or words, have been recognized correctly, it will not raise the **ResultGenerated** event.

This can result in a less than ideal experience for the user as they continue speaking and no results are provided until the recognizer has high enough confidence to raise the **ResultGenerated** event.

Handle the **HypothesisGenerated** event to improve this apparent lack of responsiveness. This event is raised whenever the recognizer generates a new set of potential matches for the word being processed. The event argument provides a **Hypothesis** property that contains the current matches. Show these to the user as they continue speaking and reassure them that processing is still active. Once confidence is high and a recognition result has been determined, replace the interim **Hypothesis** results with the final **Result** provided in the **ResultGenerated** event.

Here, we append the hypothetical text and an ellipsis ("...") to the current value of the output TextBox. The contents of the text box are updated as new hypotheses are generated and until the final results are obtained from the ResultGenerated event.

CSharp

```
private async void SpeechRecognizer_HypothesisGenerated(
  SpeechRecognizer sender,
  SpeechRecognitionHypothesisGeneratedEventArgs args)
  {

    string hypothesis = args.Hypothesis.Text;
    string textboxContent = dictatedTextBuilder.ToString() + " " +
hypothesis + " ...";

    await dispatcher.RunAsync(CoreDispatcherPriority.Normal, () =>
    {
      dictationTextBox.Text = textboxContent;
      btnClearText.IsEnabled = true;
    });
  }
```

Start and stop recognition

Before starting a recognition session, check the value of the speech recognizer State property. The speech recognizer must be in an Idle state.

After checking the state of the speech recognizer, we start the session by calling the StartAsync method of the speech recognizer's ContinuousRecognitionSession property.

CSharp

```
if (speechRecognizer.State == SpeechRecognizerState.Idle)
{
  await speechRecognizer.ContinuousRecognitionSession.StartAsync();
}
```

Recognition can be stopped in two ways:

- StopAsync lets any pending recognition events complete (ResultGenerated continues to be raised until all pending recognition operations are complete).
- CancelAsync terminates the recognition session immediately and discards any pending results.

After checking the state of the speech recognizer, we stop the session by calling the CancelAsync method of the speech recognizer's ContinuousRecognitionSession

property.

CSharp

```
if (speechRecognizer.State != SpeechRecognizerState.Idle)
{
  await speechRecognizer.ContinuousRecognitionSession.CancelAsync();
}
```

Note

A ResultGenerated event can occur after a call to CancelAsync.
Because of multithreading, a ResultGenerated event might still remain on the stack when CancelAsync is called. If so, the **ResultGenerated** event still fires.
If you set any private fields when canceling the recognition session, always confirm their values in the ResultGenerated handler. For example, don't assume a field is initialized in your handler if you set them to null when you cancel the session.

Manage issues with audio input

Article • 06/24/2021

Learn how to manage issues with speech-recognition accuracy caused by audio-input quality.

> **Important APIs**: SpeechRecognizer, RecognitionQualityDegrading, SpeechRecognitionAudioProblem

Assess audio-input quality

When speech recognition is active, use the RecognitionQualityDegrading event of your speech recognizer to determine whether one or more audio issues might be interfering with speech input. The event argument (SpeechRecognitionQualityDegradingEventArgs) provides the Problem property, which describes the issues detected with the audio input.

Recognition can be affected by too much background noise, a muted microphone, and the volume or speed of the speaker.

Here, we configure a speech recognizer and start listening for the RecognitionQualityDegrading event.

CSharp

```
private async void WeatherSearch_Click(object sender, RoutedEventArgs e)
{
    // Create an instance of SpeechRecognizer.
    var speechRecognizer = new
Windows.Media.SpeechRecognition.SpeechRecognizer();

    // Listen for audio input issues.
    speechRecognizer.RecognitionQualityDegrading +=
speechRecognizer_RecognitionQualityDegrading;

    // Add a web search grammar to the recognizer.
    var webSearchGrammar = new
Windows.Media.SpeechRecognition.SpeechRecognitionTopicConstraint(Windows.Med
ia.SpeechRecognition.SpeechRecognitionScenario.WebSearch, "webSearch");

    speechRecognizer.UIOptions.AudiblePrompt = "Say what you want to search
for...";
    speechRecognizer.UIOptions.ExampleText = "Ex. 'weather for London'";
    speechRecognizer.Constraints.Add(webSearchGrammar);
```

```
    // Compile the constraint.
    await speechRecognizer.CompileConstraintsAsync();

    // Start recognition.
    Windows.Media.SpeechRecognition.SpeechRecognitionResult
speechRecognitionResult = await speechRecognizer.RecognizeWithUIAsync();
    //await speechRecognizer.RecognizeWithUIAsync();

    // Do something with the recognition result.
    var messageDialog = new
Windows.UI.Popups.MessageDialog(speechRecognitionResult.Text, "Text
spoken");
    await messageDialog.ShowAsync();
}
```

Manage the speech-recognition experience

Use the description provided by the **Problem** property to help the user improve conditions for recognition.

Here, we create a handler for the **RecognitionQualityDegrading** event that checks for a low volume level. We then use a **SpeechSynthesizer** object to suggest that the user try speaking louder.

CSharp

```
private async void speechRecognizer_RecognitionQualityDegrading(
    Windows.Media.SpeechRecognition.SpeechRecognizer sender,

Windows.Media.SpeechRecognition.SpeechRecognitionQualityDegradingEventArgs
args)
{
    // Create an instance of a speech synthesis engine (voice).
    var speechSynthesizer =
        new Windows.Media.SpeechSynthesis.SpeechSynthesizer();

    // If input speech is too quiet, prompt the user to speak louder.
    if (args.Problem ==
Windows.Media.SpeechRecognition.SpeechRecognitionAudioProblem.TooQuiet)
    {
        // Generate the audio stream from plain text.
        Windows.Media.SpeechSynthesis.SpeechSynthesisStream stream;
        try
        {
            stream = await
speechSynthesizer.SynthesizeTextToStreamAsync("Try speaking louder");
            stream.Seek(0);
        }
        catch (Exception)
        {
```

```
            stream = null;
        }

        // Send the stream to the MediaElement declared in XAML.
        await
CoreApplication.MainView.CoreWindow.Dispatcher.RunAsync(Windows.UI.Core.Core
DispatcherPriority.High, () =>
        {
            this.media.SetSource(stream, stream.ContentType);
        });
    }
}
```

Set speech recognition timeouts

Article • 06/24/2021

Set how long a speech recognizer ignores silence or unrecognizable sounds (babble) and continues listening for speech input.

> **Important APIs**: Timeouts, SpeechRecognizerTimeouts

Set a timeout

Here, we specify various **Timeouts** values:

- InitialSilenceTimeout - The length of time that a SpeechRecognizer detects silence (before any recognition results have been generated) and assumes speech input is not forthcoming.
- BabbleTimeout - The length of time that a SpeechRecognizer continues to listen to unrecognizable sounds (babble) before it assumes speech input has ended and finalizes the recognition operation.
- EndSilenceTimeout - The length of time that a SpeechRecognizer detects silence (after recognition results have been generated) and assumes speech input has ended.

Note Timeouts can be set on a per-recognizer basis.

CSharp

```
// Set timeout settings.
recognizer.Timeouts.InitialSilenceTimeout = TimeSpan.FromSeconds(6.0);
recognizer.Timeouts.BabbleTimeout = TimeSpan.FromSeconds(4.0);
recognizer.Timeouts.EndSilenceTimeout = TimeSpan.FromSeconds(1.2);
```

Cortana interactions in Windows apps

Article • 10/02/2024

> ⚠ **Warning**
>
> This feature is no longer supported as of the Windows 10 May 2020 Update (version 2004, codename "20H1").

Extend the basic functionality of **Cortana** with voice commands that launch and execute a single action in a Windows application.

The target app can be launched in the foreground (the app takes focus and **Cortana** is dismissed) or activated in the background (**Cortana** retains focus but provides results from the app), depending on the complexity of the interaction. Generally, voice commands that require additional context or user input are best handled in a foreground app, while basic commands can be handled in **Cortana** through a background app.

By integrating the basic functionality of your app, and providing a central entry point for the user to accomplish most of the tasks without opening your app directly, **Cortana** becomes a liaison between your app and the user. Providing this shortcut to app functionality and reducing the need to switch apps, can save the user significant time and effort.

> ⓘ **Note**
>
> A voice command is a single utterance with a specific intent, defined in a Voice Command Definition (VCD) file, directed at an installed app via **Cortana**.
>
> A VCD file defines one or more voice commands, each with a unique intent.
>
> Voice command definitions can vary in complexity. They can support anything from a single, constrained utterance to a collection of more flexible, natural language utterances, all denoting the same intent.

Other speech and conversation components

Speech, voice, and conversation in Windows 10

See Speech, voice, and conversation in Windows 10 for information on how the various Windows development frameworks provide speech recognition, speech synthesis, and conversation support for developers building Windows applications.

Cortana design guidelines

Article • 06/24/2021

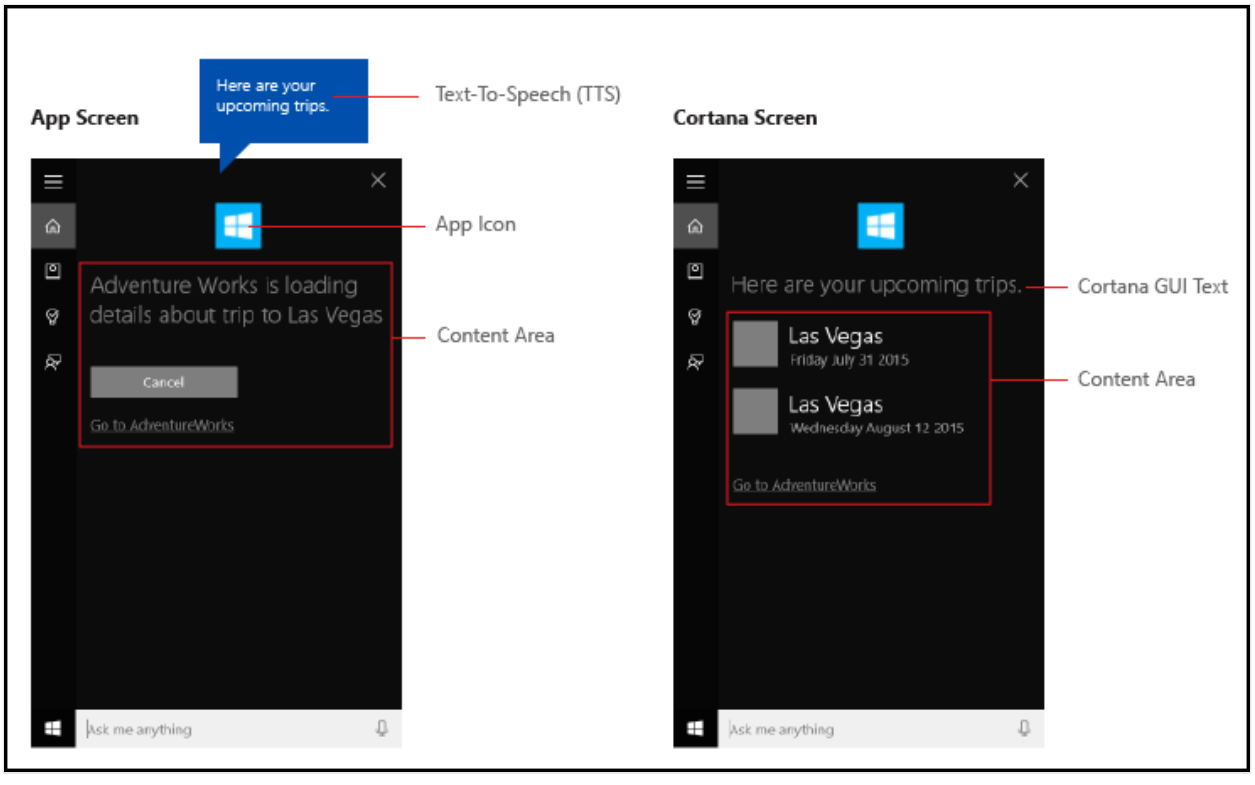
> **⚠ Warning**
>
> This feature is no longer supported as of the Windows 10 May 2020 Update (version 2004, codename "20H1").

These guidelines and recommendations describe how your app can best use **Cortana** to interact with the user, help them accomplish a task, and communicate clearly how it's all happening.

Cortana enables applications running in the background to prompt the user for confirmation or disambiguation, and in return provide the user with feedback on the status of the voice command. The process is lightweight, quick, and doesn't force the user to leave the **Cortana** experience or switch context to the application.

While the user should feel that **Cortana** is helping to make the process as light and easy as possible, you probably want **Cortana** to also be explicit that it's your app accomplishing the task.

We use a trip planning and management app named **Adventure Works** integrated into the **Cortana** UI, shown here, to demonstrate many of the concepts and features we discuss. For more info, see the Cortana voice command sample.



Conversational writing

Successful **Cortana** interactions require you to follow some fundamental principles when crafting text-to-speech (TTS) and GUI strings.

Expand table

Principle	Bad example	Good example
Efficient Use as few words as possible and put the most important information up front.	Sure can do, what movie would you like to search for today? We have a large collection.	Sure, what movie are you looking for?
Relevant Provide information pertinent only to the task, content, and context.	I've added this to your playlist. Just so you know, your battery is getting low.	I've added this to your playlist.
Clear Avoid ambiguity. Use everyday language instead of technical jargon.	No results for query "Trips to Las Vegas".	I couldn't find any trips to Las Vegas.
Trustworthy Be as accurate as possible. Be transparent about what's going on in the background—if a task hasn't finished yet, don't say that it has. Respect privacy—don't read private information out loud.	I couldn't find that movie, it must not have been released yet.	I couldn't find that movie in our catalogue.

Write how people speak. Don't emphasize grammatical accuracy over sounding natural. For example, ear-friendly verbal shortcuts like "wanna" or "gotta" are fine for TTS read out.

Use the implied first-person tense where possible and natural. For example, "Looking for your next Adventure Works trip" implies that someone is doing the looking, but does not use the word "I" to specify.

Use some variation to help make your app sound more natural. Provide different versions of your TTS and GUI strings to effectively say the same thing. For example, "What movie do you wanna see?" could have alternatives like "What movie would you like to watch?". People don't say the same thing the exact same way every time. Just make sure to keep your TTS and GUI versions in sync.

Use phrases like "OK" and "Alright" in your responses judiciously. While they can provide acknowledgment and a sense of progress, they can also get repetitive if used too often and without variation.

> ⓘ **Note**
>
> Use acknowledgment phrases in TTS only. Due to the limited space on the **Cortana** canvas, don't repeat them in the corresponding GUI strings.

Use contractions in your responses for more natural interactions and additional space saving on the **Cortana** canvas. For example," I can't find that movie" instead of "I was unable to find that movie". Write for the ear, not the eye.

Use language that the system understands. Users tend to repeat the terms they are presented with. Know what you display.

Use some variation in your responses by rotating, or randomly selecting, from a collection of alternative responses. For example, "What movie do you wanna see?" and "What film would you like to watch?". This makes your app sound more natural and unique.

Localization

To initiate an action using a voice command, your app must register voice commands in the language the user has selected on their device (Settings > System > Speech > Speech Language).

You should localize the voice commands your app responds to and all TTS and GUI strings.

You should avoid lengthy GUI strings. The **Cortana** canvas provides three lines for responses and will truncate strings longer than that.

For more info, see the Globalization and localization section.

Image resources and scaling

Universal Windows Platform (UWP) apps can automatically select the most appropriate app logo image based on specific settings and device capabilities (high contrast, effective pixels, locale, and so on). All you need to do is provide the images and ensure you use the appropriate naming convention and folder organization within the app project for the different resource versions. If you don't provide the recommended

resource versions, accessibility, localization, and image quality can suffer, depending on the user's preferences, abilities, device type, and location.

For more detail on image resources for high contrast and scale factors, see Guidelines for tile and icon assets.

You name resources using qualifiers. Resource qualifiers are folder and filename modifiers that identify the context in which a particular version of a resource should be used.

The standard naming convention is "foldername/qualifiername-value[_qualifiername-value]/filename.qualifiername-value[_qualifiername-value].ext". For example: images/logo.scale-100_contrast-white.png is simply referred to in code using the root folder and the filename: images/logo.png. See Manage language and region and How to name resources using qualifiers.

We recommend that you mark the default language on string resource files (such as "en-US\resources.resw") and the default scale factor on images (such as "logo.scale-100.png"), even if you do not currently plan to provide localized or multiple resolution resources. However, at a minimum, we recommend that you provide assets for 100, 200, and 400 scale factors.

> **ⓘ Important**
>
> The app icon used in the title area of the Cortana canvas is the Square44x44Logo icon specified in the "Package.appxmanifest" file.

You can also specify an icon for each result tile for a user query. Valid image sizes for results icons are:

- 68w x 68h
- 68w x 92h
- 280w x 140h

Result tile templates

A set of templates are provided for the result tiles displayed on the Cortana canvas. Use these templates to specify the tile title and whether the tile includes text and a result icon image. Each tile can include up to three lines of text and one image, depending on the template specified.

Here are the supported templates (with examples):

Expand table

Name	Example
Title only	Title with text	Title with 68x68 icon	no image

Name	Example
Title with 68x68 icon and text	Title with 68x92 icon	no image
Title with 68x92 icon and text	Title with 280x140 icon	no image

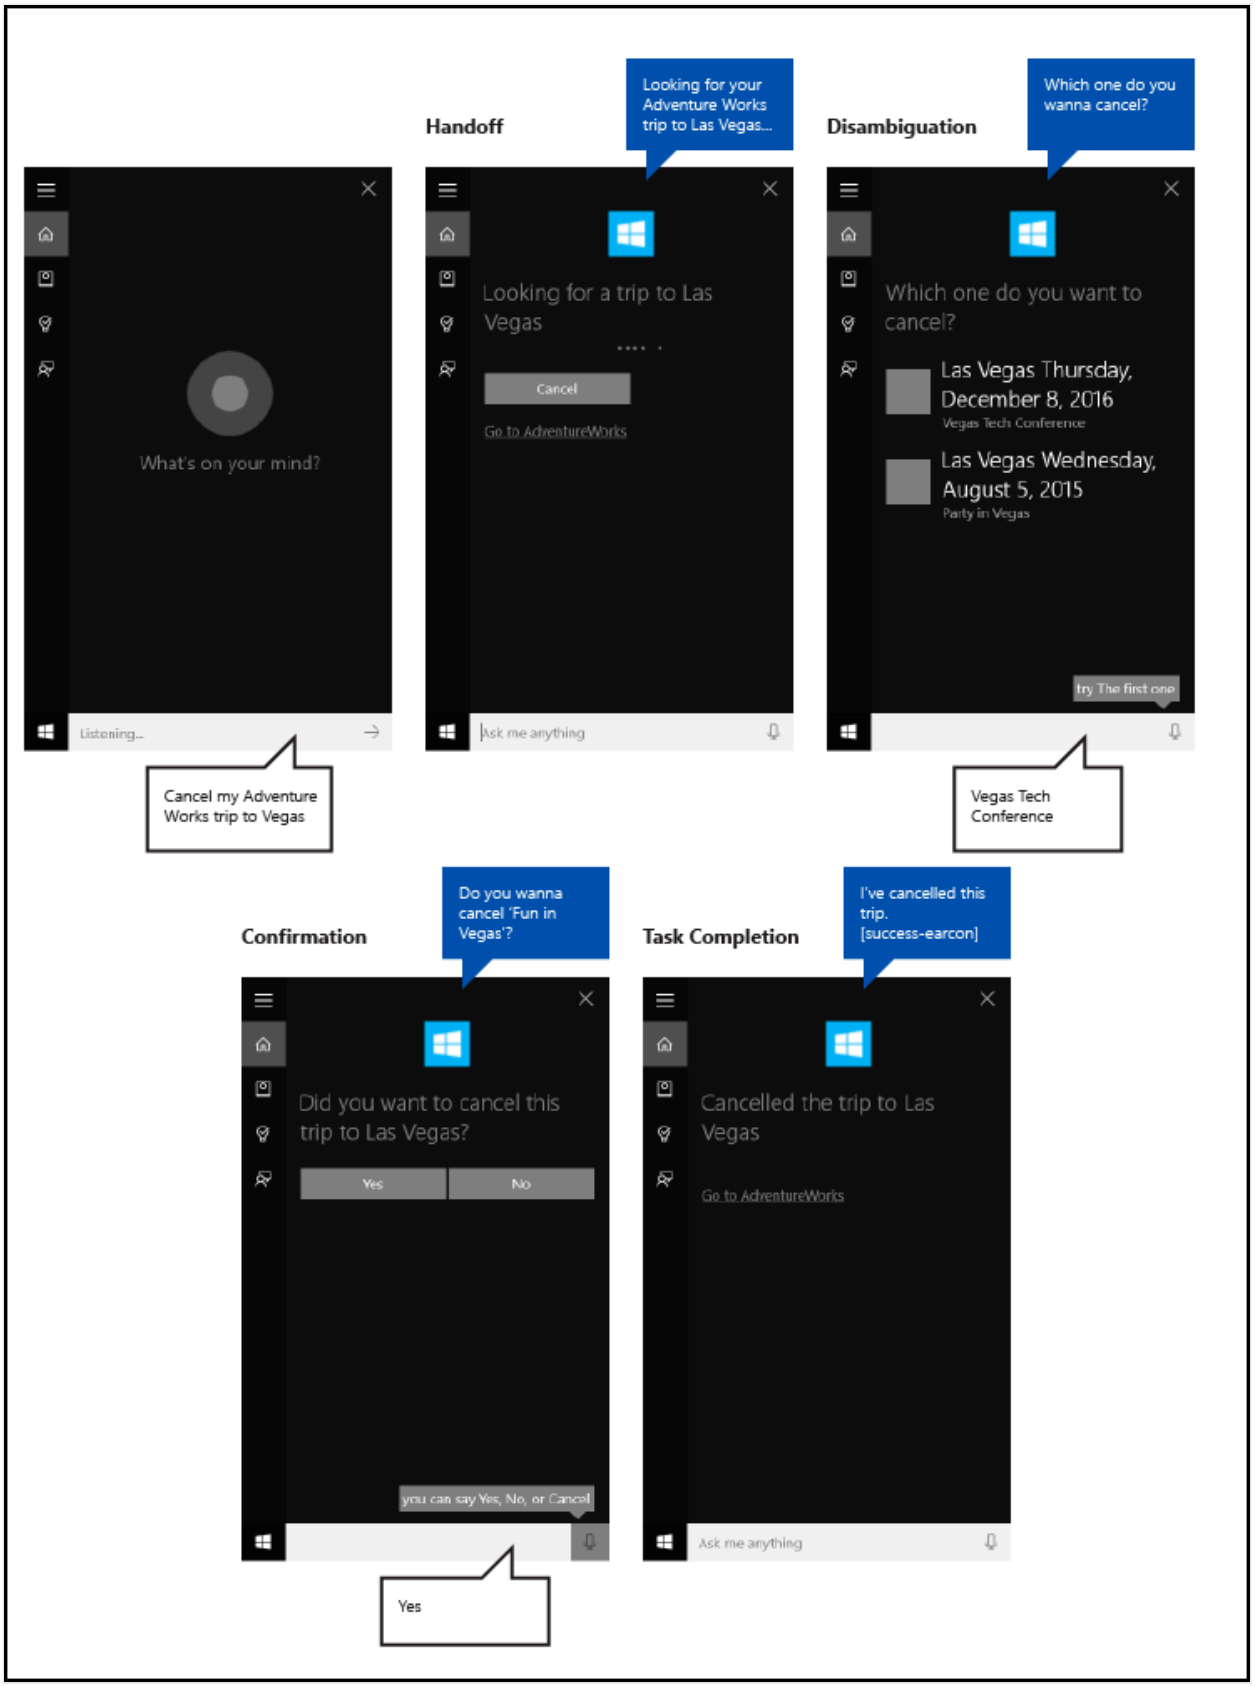
Name	Example
Title with 280x140 icon and text	
See VoiceCommandContentTileType for more info on Cortana templates.

Example

This example demonstrates an end-to-end task flow for a background app in **Cortana**. We're using the **Adventure Works** app to cancel a trip to Las Vegas. This example uses the "Title with 68x68 icon and text" template.



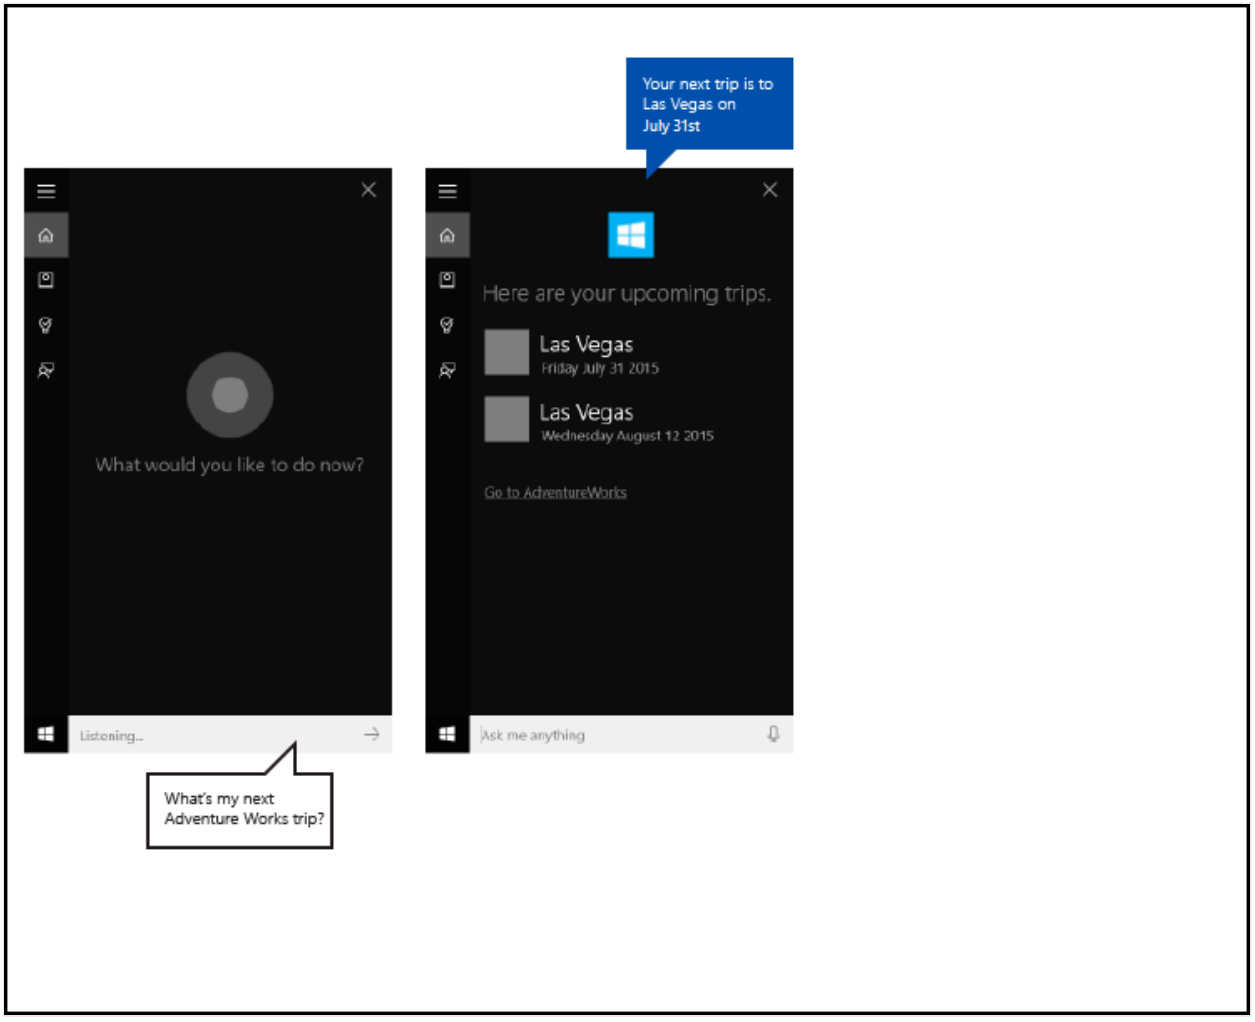
Here are the steps outlined in this image:

1. The user taps the microphone to initiate **Cortana**.
2. The user says "Cancel my Adventure Works trip to Vegas" to launch the **Adventure Works** app in the background. The app uses both **Cortana** speech and canvas to interact with the user.

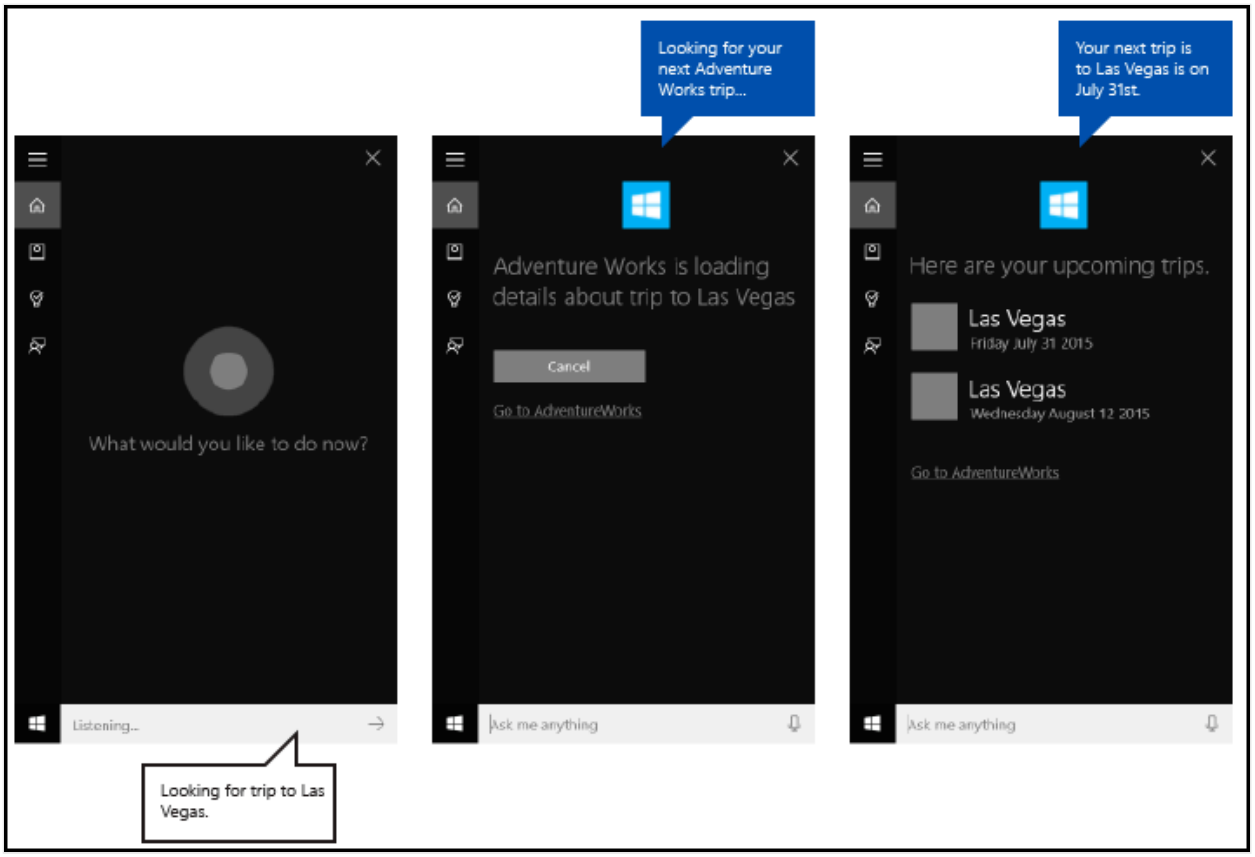
3. **Cortana** transitions to a handoff screen that gives the user acknowledgment feedback ("I'll get Adventure Works on that."), a status bar, and a cancel button.
4. In this case, the user has multiple trips that match the query, so the app provides a disambiguation screen that lists all the matching results and asks, "Which one do you wanna cancel?"
5. The user specifies the "Vegas Tech Conference" item.
6. As the cancellation cannot be undone, the app provides a confirmation screen that asks the user to confirm their intent.
7. The user says "Yes".
8. The app then provides a completion screen that shows the result of the operation.

We explore these steps in more detail here.

Handoff



AdventureWorks "Upcoming trip" with no handoff screen



AdventureWorks "Upcoming trip" with handoff screen

Tasks that take less than 500ms for your app to respond, and require no additional information from the user, can be completed without further participation from **Cortana**, other than displaying the completion screen.

If your application requires more than 500ms to respond, **Cortana** provides a handoff screen. The app icon and name are displayed, and you must provide both GUI and TTS handoff strings to indicate that the voice command was correctly understood. The handoff screen will be shown for up to 5 seconds; if your app doesn't respond within this time, **Cortana** presents a generic error screen.

GUI and TTS guidelines for handoff screens

Clearly indicate that the task is in progress.

Use present tense.

Use an action verb that confirms what task is initiating and reference the specific entity.

Use a generic verb that doesn't commit to the requested, incomplete action. For example, "Looking for your trip" instead of "Canceling your trip". In this case, if no results are returned the user doesn't hear something like "Cancelling your trip to Las Vegas... I couldn't find a trip to Las Vegas".

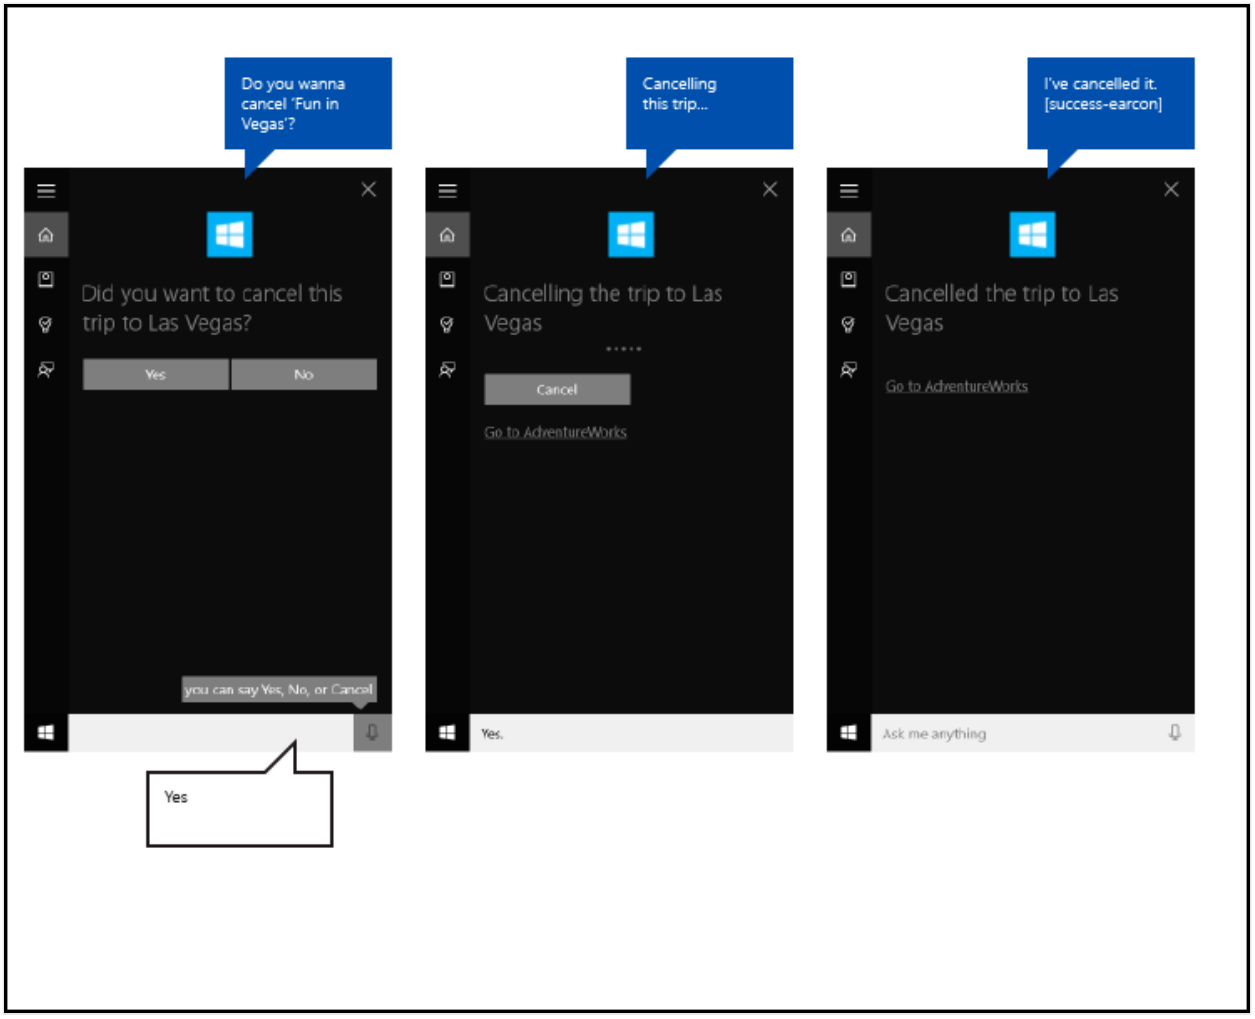
Be clear that the task hasn't already taken place if the app still needs to resolve the entity requested. For example, notice how we say "Looking for your trip" instead of "Cancelling your trip" because zero or more trips can be matched, and we don't know the result yet.

The GUI and TTS strings can be the same, but don't need to be. Try to keep the GUI string short to avoid truncation and duplication of other visual assets.

Expand table

TTS	GUI
Looking for your next Adventure Works trip.	Looking for your next trip...
Searching for your Adventure Works trip to Falls City.	Searching for trip to Falls City...

Progress



AdventureWorks "Cancel trip" progress

When a task takes a while between steps, your app needs to step in and update the user on what's happening on a progress screen. The app icon is displayed, and you must

provide both GUI and TTS progress strings to indicate that the task is underway.

You should provide a link to your app with launch parameters to start the app in the appropriate state. This lets the user view or complete the task themselves. **Cortana** provides the link text (such as, "Go to Adventure Works").

Progress screens will show for 5 seconds each, after which they must be followed by another screen or the task will time out.

These screens can follow a progress screen:

- Progress
- Confirmation (explicit, described later)
- Disambiguation
- Completion

GUI and TTS guidelines for progress screens

Use present tense.

Use an action verb that confirms the task is underway.

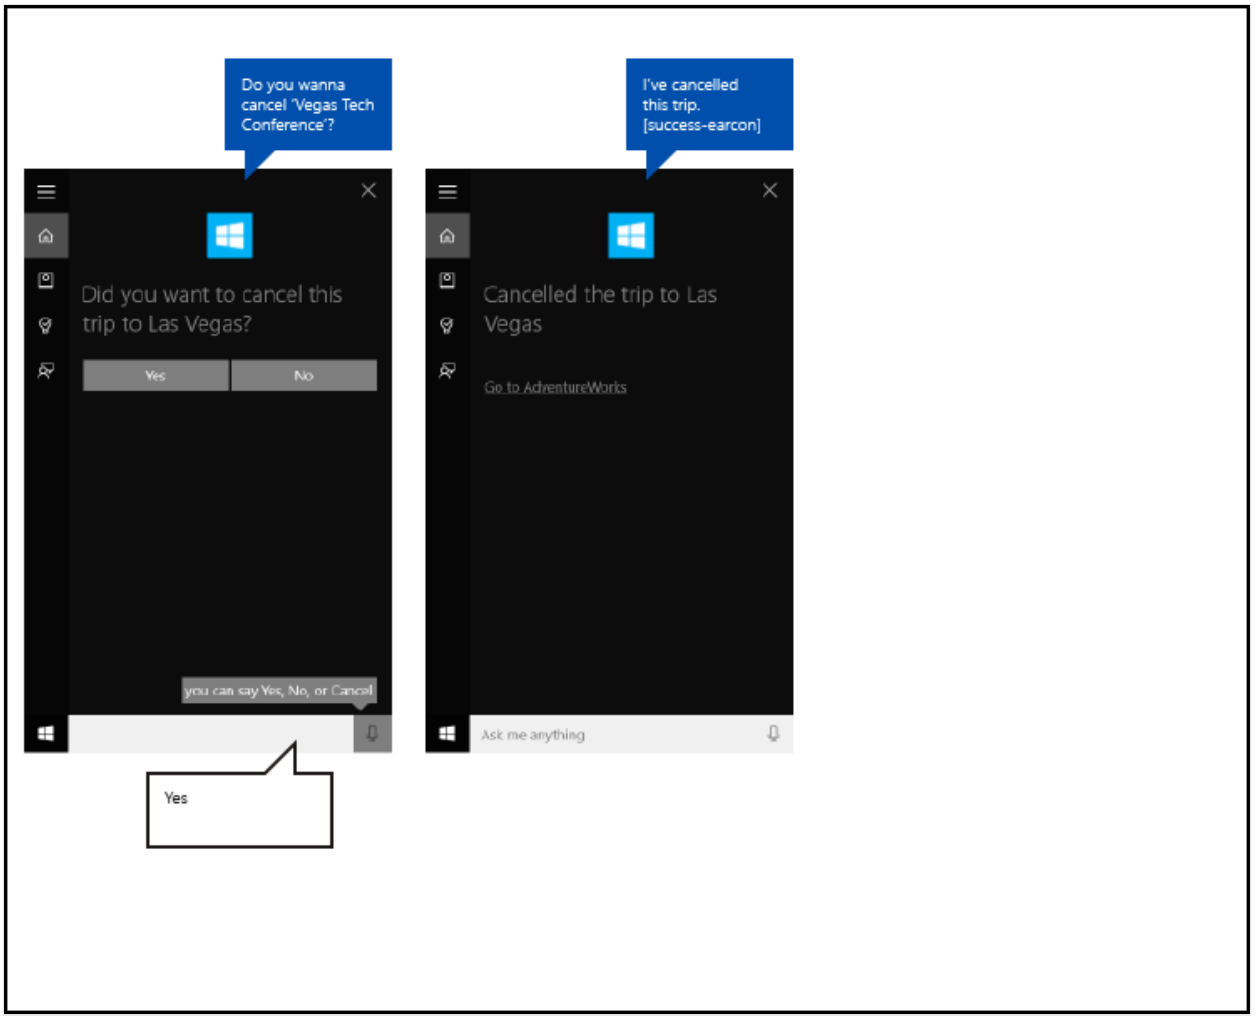
GUI: If the entity is shown, use a reference to it ("Cancelling this trip..."); if no entity is shown, explicitly call out the entity ("Cancelling 'Vegas Tech Conference'").

TTS: You should only include a TTS string on the first progress screen. If further progress screens are required, send an empty string, {}, as your TTS string, and provide a GUI string only.

Expand table

Conditions	TTS	GUI
ENTITY READ ON PRIOR TURN / ENTITY SHOWN ON DISPLAY	Cancelling this trip...	Cancelling this trip...
ENTITY NOT READ ON PRIOR TURN / ENTITY SHOWN ON DISPLAY	Cancelling your trip to Vegas...	Cancelling this trip...
ENTITY NOT READ ON PRIOR TURN / ENTITY NOT SHOWN	Cancelling your trip to Vegas...	Cancelling your trip to Vegas...

Confirmation



AdventureWorks "Cancel trip" confirmation

Some tasks can be implicitly confirmed by the nature of the user's command; others are potentially more sensitive and require explicit confirmation. Here are some guidelines for when to use explicit vs. implicit confirmation.

Both GUI and TTS strings on the confirmation screen are specified by your app, and the app icon, if provided, is shown instead of the **Cortana** avatar.

After the customer responds to the confirmation, your application must provide the next screen within 500 ms to avoid going to a progress screen.

Use explicit when...

- Content is leaving the user (such as, a text message, email, or social post)
- An action can't be undone (such as, making a purchase or deleting something)
- The result could be embarrassing (such as, calling the wrong person)
- More complex recognition is required (such as, open-ended transcription)

Use implicit when...

- Content is saved for the user only (such as, a note-to-self)
- There's an easy way to back out (such as, turning an alarm on or off)

- The task needs to be quick (such as, quickly capturing an idea before forgetting)
- Accuracy is high (such as, a simple menu)

GUI and TTS guidelines for confirmation screens

Use present tense.

Ask the user an unambiguous question that can be answered with "Yes" or "No". The question should explicitly confirm what the user is trying to do and there should be no other obvious options.

Provide a variation of the question for a re-prompt, in case the voice command is not understood the first time.

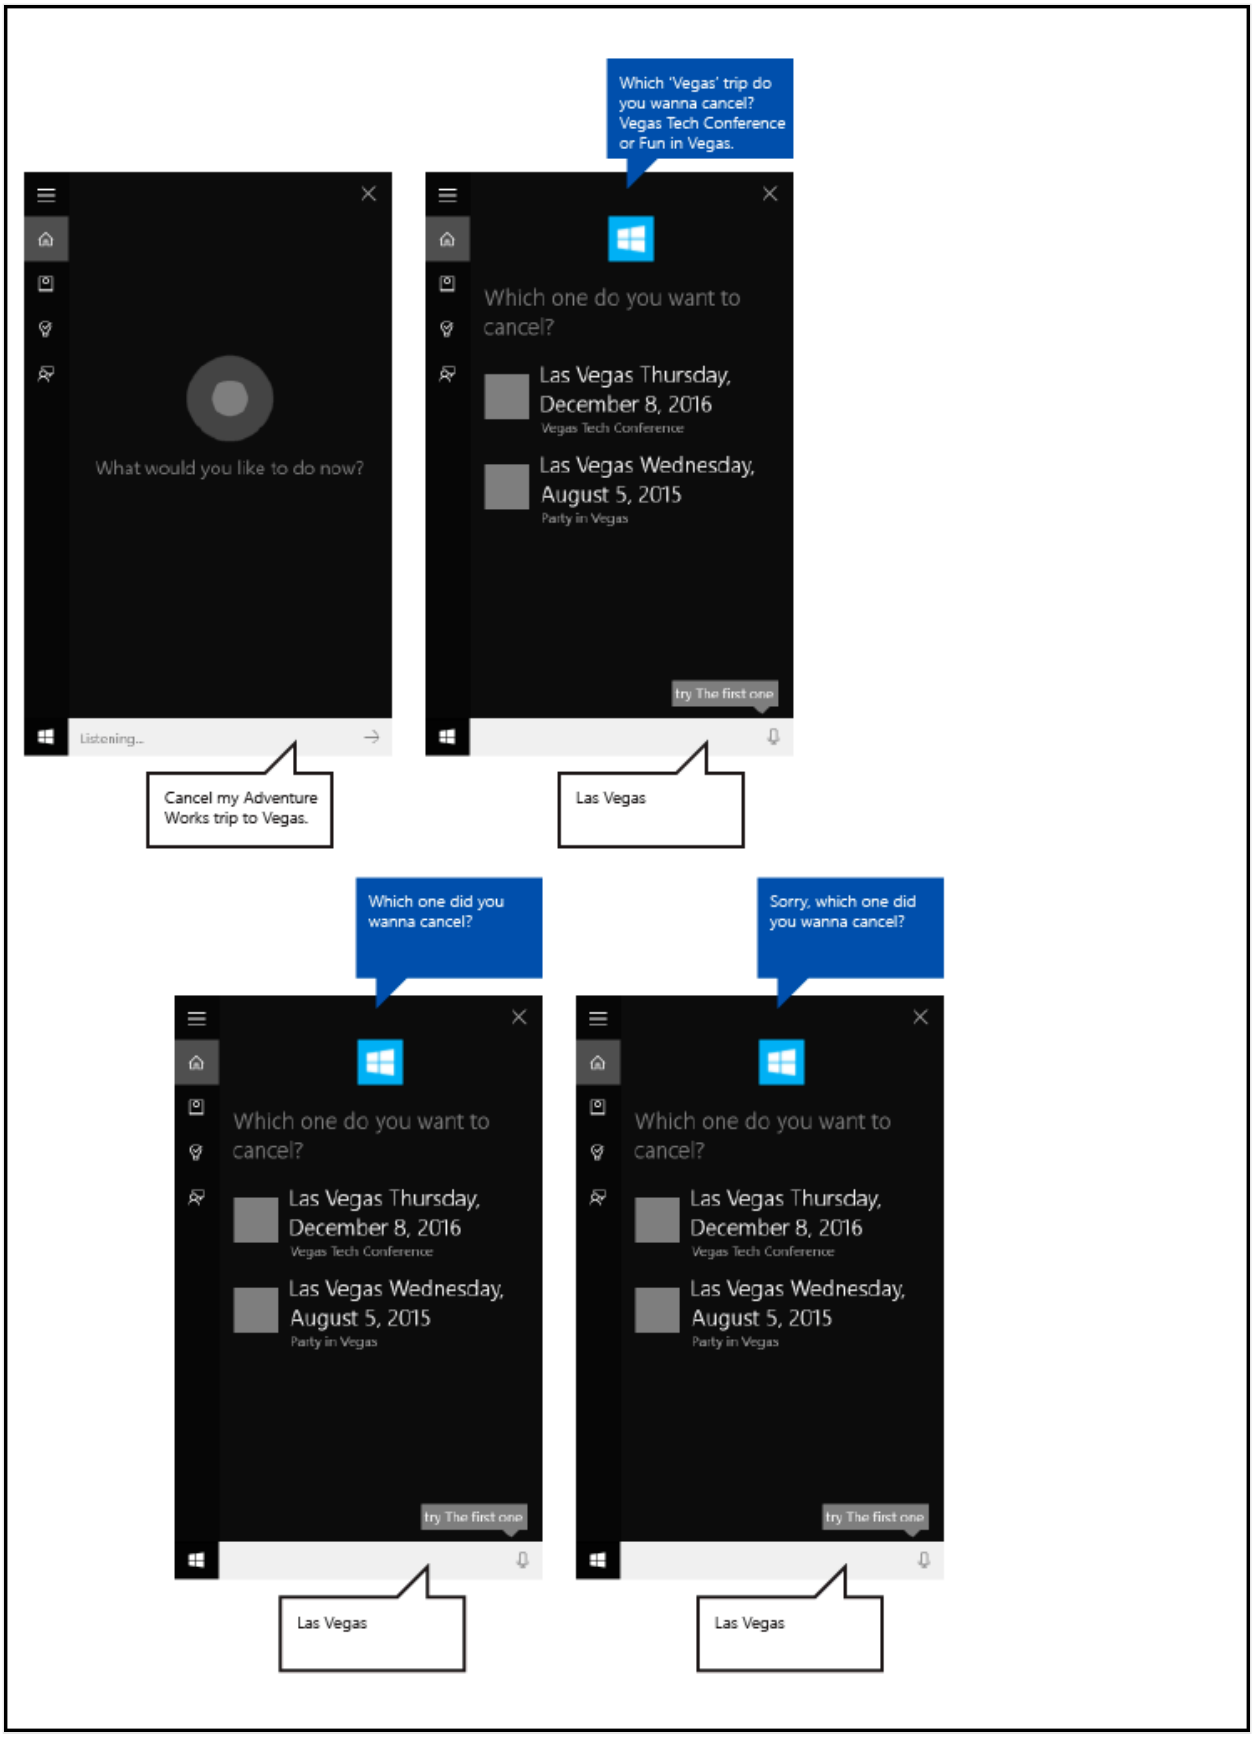
GUI: If the entity is shown, use a reference to it. If no entity is shown, explicitly call out the entity.

TTS: For clarity, always reference the specific item or entity, unless it was read out by the system on the previous turn.

Expand table

Conditions	TTS	GUI
ENTITY NOT READ ON PRIOR TURN / ENTITY SHOWN ON DISPLAY	Do you wanna cancel Vegas Tech Conference?	Cancel this trip?
ENTITY NOT READ ON PRIOR TURN / ENTITY NOT SHOWN	Do you wanna cancel Vegas Tech Conference?	Cancel Vegas Tech Conference?
ENTITY READ ON PRIOR TURN / ENTITY NOT SHOWN	Do you wanna cancel this trip?	Cancel this trip?
REPROMPT WITH ENTITY SHOWN	Did you wanna cancel this trip?	Did you want to cancel this trip?
REPROMPT WITH ENTITY NOT SHOWN	Did you wanna cancel this trip?	Did you want to cancel Vegas Tech Conference?

Disambiguation



AdventureWorks "Cancel trip" disambiguation

Some tasks might require the user to select from a list of entities to complete the task.

Both GUI and TTS strings on the disambiguation screen are specified by your app, and the app icon, if provided, is shown instead of the **Cortana** avatar.

After the customer responds to the disambiguation question, your application must provide the next screen within 500 ms to avoid going to a progress screen.

GUI and TTS guidelines for disambiguation screens

Use present tense.

Ask the user an unambiguous question that can be answered with the title or text line of any entity displayed.

Up to 10 entities can be displayed.

Each entity should have a unique title.

Provide a variation of the question for a re-prompt, in case the voice command is not understood the first time.

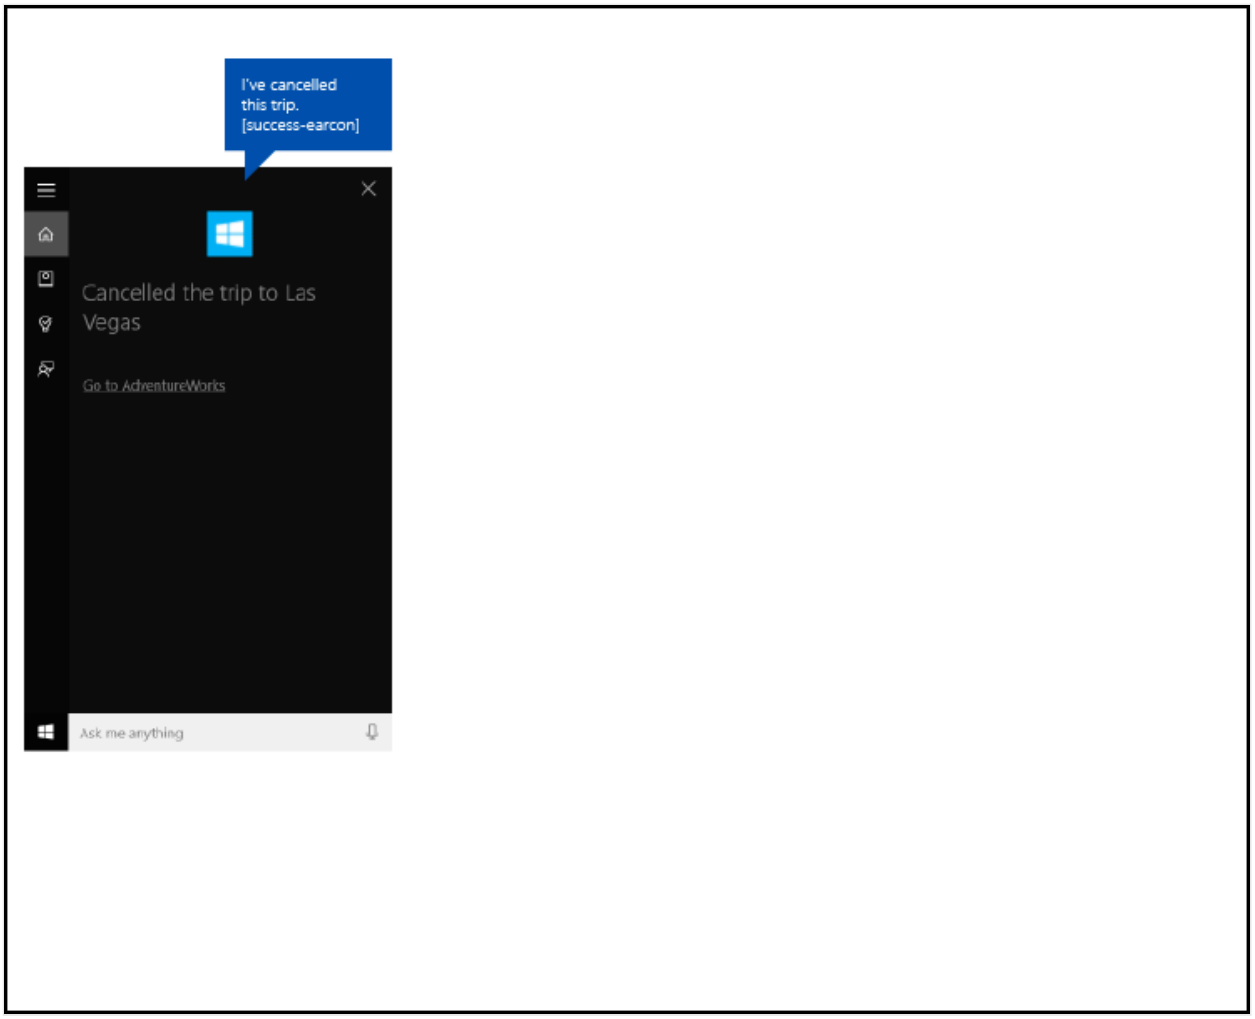
TTS: For clarity, always reference the specific item or entity, unless it was spoken on the previous turn.

TTS: Don't read out the entity list, unless there are three or fewer and they are short.

Expand table

Conditions	TTS	GUI
PROMPT - 3 OR FEWER ITEMS	Which Vegas trip do you wanna cancel? Vegas Tech Conference or Party in Vegas?	Which one do you want to cancel?
PROMPT - MORE THAN 3 ITEMS	Which Vegas trip do you wanna cancel?	Which one do you want to cancel?
REPROMPT	Which Vegas trip did you wanna cancel?	Which one do you want to cancel?

Completion



AdventureWorks "Cancel trip" completion

On successful task completion, your app should inform the user that the requested task was completed successfully.

Both GUI and TTS strings on the completion screen are specified by your app, and the app icon, if provided, is shown instead of the **Cortana** avatar.

You should provide a link to your app with launch parameters to start the app in the appropriate state. This lets the user view or complete the task themselves. **Cortana** provides the link text (such as, "Go to Adventure Works").

GUI and TTS guidelines for completion screens

Use past tense.

Use an action verb to explicitly state that the task has completed.

If the entity is shown, or it has been referenced on prior turn, only reference it.

Expand table

Conditions	TTS	GUI
ENTITY SHOWN / ENTITY READ ON PRIOR TURN	I've cancelled this trip.	Cancelled this trip.
ENTITY NOT SHOWN / ENTITY NOT READ ON PRIOR TURN	I've cancelled your Vegas Tech Conference trip.	Cancelled "Vegas Tech Conference."

Error

AdventureWorks "Cancel trip" error

When one of the following errors occur, **Cortana** displays the same generic error message.

- The app service terminates unexpectedly.
- **Cortana** fails to communicate with the app service.
- The app fails to provide a screen after **Cortana** shows a handoff screen or a progress screen for 5 seconds.

Activate a foreground app with voice commands through Cortana

Article • 06/24/2021

> ⚠ **Warning**
>
> This feature is no longer supported as of the Windows 10 May 2020 Update (version 2004, codename "20H1").

In addition to using voice commands within **Cortana** to access system features, you can also extend **Cortana** with features and functionality from your app. Using voice commands, your app can be activated to the foreground and an action or command executed within the app.

> ⓘ **Note**
>
> **Important APIs**
>
> - Windows.ApplicationModel.VoiceCommands
> - VCD elements and attributes v1.2

When an app handles a voice command in the foreground, it takes focus and Cortana is dismissed. If you prefer, you can activate your app and execute a command as a background task. In this case, Cortana retains focus and your app returns all feedback and results through the **Cortana** canvas and the **Cortana** voice.

Voice commands that require additional context or user input (such as sending a message to a specific contact) are best handled in a foreground app, while basic commands (such as listing upcoming trips) can be handled in **Cortana** through a background app.

If you want to activate an app in the background using voice commands, see Activate a background app in Cortana using voice commands.

> ⓘ **Note**
>
> A voice command is a single utterance with a specific intent, defined in a Voice Command Definition (VCD) file, directed at an installed app via **Cortana**.

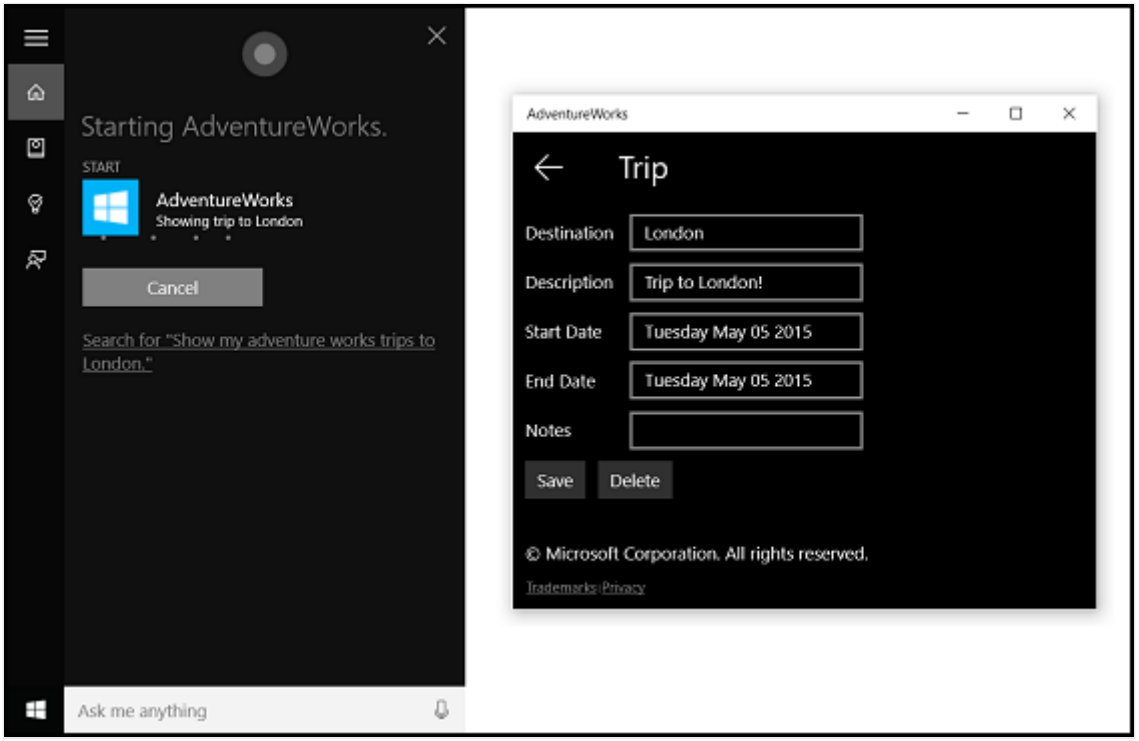
A VCD file defines one or more voice commands, each with a unique intent.

Voice command definitions can vary in complexity. They can support anything from a single, constrained utterance to a collection of more flexible, natural language utterances, all denoting the same intent.

To demonstrate foreground app features, we'll use a trip planning and management app named **Adventure Works** from the Cortana voice command sample .

To create a new **Adventure Works** trip without **Cortana**, a user would launch the app and navigate to the **New trip** page. To view an existing trip, a user would launch the app, navigate to the **Upcoming trips** page, and select the trip.

Using voice commands through **Cortana**, the user can instead just say, "Adventure Works add a trip" or "Add a trip on Adventure Works" to launch the app and navigate to the **New trip** page. In turn, saying "Adventure Works, show my trip to London" will launch the app and navigate to the **Trip** detail page, shown here.



These are the basic steps to add voice-command functionality and integrate Cortana with your app using speech or keyboard input:

1. Create a VCD file. This is an XML document that defines all the spoken commands that the user can say to initiate actions or invoke commands when activating your app. See **VCD elements and attributes v1.2**.
2. Register the command sets in the VCD file when the app is launched.
3. Handle the activation-by-voice-command, navigation within the app, and execution of the command.

> **Tip**
>
> **Prerequisites**
>
> If you're new to developing Universal Windows Platform (UWP) apps, have a look through these topics to get familiar with the technologies discussed here.
>
> - Create your first app
> - Learn about events with Events and routed events overview
>
> **User experience guidelines**
>
> See Cortana design guidelines for info about how to integrate your app with **Cortana** and Speech interactions for helpful tips on designing a useful and engaging speech-enabled app.

Create a new solution with project in Visual Studio

1. Launch Microsoft Visual Studio 2015.

   The Visual Studio 2015 Start page appears.

2. On the **File** menu, select **New** > **Project**.

   The **New Project** dialog appears. The left pane of the dialog lets you select the type of templates to display.

3. In the left pane, expand **Installed** > **Templates** > **Visual C#** > **Windows**, then pick the **Universal** template group. The dialog's center pane displays a list of project templates for Universal Windows Platform (UWP) apps.

4. In the center pane, select the **Blank App (Universal Windows)** template.

   The **Blank App** template creates a minimal UWP app that compiles and runs, but contains no user-interface controls or data. You add controls to the app over the course of this tutorial.

5. In the **Name** text box, type your project name. For this example, we use "AdventureWorks".

6. Click **OK** to create the project.

Microsoft Visual Studio creates your project and displays it in the **Solution Explorer**.

Add image assets to project and specify them in the app manifest

UWP apps can automatically select the most appropriate images based on specific settings and device capabilities (high contrast, effective pixels, locale, and so on). All you need to do is provide the images and ensure you use the appropriate naming convention and folder organization within the app project for the different resource versions. If you don't provide the recommended resource versions, accessibility, localization, and image quality can suffer, depending on the user's preferences, abilities, device type, and location.

For more detail on image resources for high contrast and scale factors, see Guidelines for tile and icon assets.

You name resources using qualifiers. Resource qualifiers are folder and filename modifiers that identify the context in which a particular version of a resource should be used.

The standard naming convention is `foldername/qualifiername-value[_qualifiername-value]/filename.qualifiername-value[_qualifiername-value].ext`. For example, `images/logo.scale-100_contrast-white.png`, which can be referred to in code using just the root folder and the filename: `images/logo.png`. See How to name resources using qualifiers.

We recommend that you mark the default language on string resource files (such as `en-US\resources.resw`) and the default scale factor on images (such as `logo.scale-100.png`), even if you do not currently plan to provide localized or multiple resolution resources. However, at a minimum, we recommend that you provide assets for 100, 200, and 400 scale factors.

> **Important**
>
> The app icon used in the title area of the **Cortana** canvas is the Square44x44Logo icon specified in the "Package.appxmanifest" file.

Create a VCD file

1. In Visual Studio, right-click your primary project name, select **Add** > **New Item**. Add an **XML File**.
2. Type a name for the VCD file (for this example, "AdventureWorksCommands.xml"), and click Add.
3. In **Solution Explorer**, select the VCD file.
4. In the **Properties** window, set **Build action** to **Content**, and then set **Copy to output directory** to **Copy if newer**.

Edit the VCD file

Add a **VoiceCommands** element with an **xmlns** attribute pointing to `https://schemas.microsoft.com/voicecommands/1.2`.

1. For each language supported by your app, create a CommandSet element that contains the voice commands supported by your app.

   You can declare multiple CommandSet elements, each with a different xml:lang attribute so your app to be used in different markets. For example, an app for the United States might have a CommandSet for English and a CommandSet for Spanish.

   > ⊗ **Caution**
   >
   > To activate an app and initiate an action using a voice command, the app must register a VCD file that contains a CommandSet with a language that matches the speech language selected by the user for their device. The speech language is located in **Settings** > **System** > **Speech** > **Speech Language**.

2. Add a **Command** element for each command you want to support. Each **Command** declared in a VCD file must include the following information:

   - An **AppName** attribute that your application uses to identify the voice command at runtime.
   - An **Example** element that contains a phrase describing how a user can invoke the command. **Cortana** shows this example when the user says "What can I say?", "Help", or they tap **See more**.
   - A **ListenFor** element that contains the words or phrases that your app recognizes as a command. Each **ListenFor** element can contain references to one or more **PhraseList** elements that contain specific words relevant to the command.

> **Note**
>
> **ListenFor** elements cannot be programmatically modified. However, **PhraseList** elements associated with **ListenFor** elements can be programmatically modified. Applications should modify the content of the **PhraseList** at runtime based on the data set generated as the user uses the app. See Dynamically modify Cortana VCD phrase lists.

A **Feedback** element that contains the text for **Cortana** to display and speak as the application is launched.

A **Navigate** element indicates that the voice command activates the app to the foreground. In this example, the `showTripToDestination` command is a foreground task.

A **VoiceCommandService** element indicates that the voice command activates the app in the background. The value of the **Target** attribute of this element should match the value of the **Name** attribute of the **uap:AppService** element in the package.appxmanifest file. In this example, the `whenIsTripToDestination` and `cancelTripToDestination` commands are background tasks that specify the name of the app service as "AdventureWorksVoiceCommandService".

For more detail, see the **VCD elements and attributes v1.2** reference.

Here's a portion of the **VCD** file that defines the en-us voice commands for the **Adventure Works** app.

XML

```
<?xml version="1.0" encoding="utf-8" ?>
<VoiceCommands xmlns="https://schemas.microsoft.com/voicecommands/1.2">
  <CommandSet xml:lang="en-us" Name="AdventureWorksCommandSet_en-us">
    <AppName> Adventure Works </AppName>
    <Example> Show trip to London </Example>

    <Command Name="showTripToDestination">
      <Example> Show trip to London </Example>
      <ListenFor RequireAppName="BeforeOrAfterPhrase"> show [my] trip to
{destination} </ListenFor>
      <ListenFor RequireAppName="ExplicitlySpecified"> show [my]
{builtin:AppName} trip to {destination} </ListenFor>
      <Feedback> Showing trip to {destination} </Feedback>
      <Navigate />
    </Command>

    <Command Name="whenIsTripToDestination">
      <Example> When is my trip to Las Vegas?</Example>
      <ListenFor RequireAppName="BeforeOrAfterPhrase"> when is [my] trip to
```

```
{destination}</ListenFor>
      <ListenFor RequireAppName="ExplicitlySpecified"> when is [my]
{builtin:AppName} trip to {destination} </ListenFor>
      <Feedback> Looking for trip to {destination}</Feedback>
      <VoiceCommandService Target="AdventureWorksVoiceCommandService"/>
    </Command>

    <Command Name="cancelTripToDestination">
      <Example> Cancel my trip to Las Vegas </Example>
      <ListenFor RequireAppName="BeforeOrAfterPhrase"> cancel [my] trip to
{destination}</ListenFor>
      <ListenFor RequireAppName="ExplicitlySpecified"> cancel [my]
{builtin:AppName} trip to {destination} </ListenFor>
      <Feedback> Cancelling trip to {destination}</Feedback>
      <VoiceCommandService Target="AdventureWorksVoiceCommandService"/>
    </Command>

    <PhraseList Label="destination">
      <Item>London</Item>
      <Item>Las Vegas</Item>
      <Item>Melbourne</Item>
      <Item>Yosemite National Park</Item>
    </PhraseList>
  </CommandSet>
```

Install the VCD commands

Your app must run once to install the VCD.

> **Note**
>
> Voice command data is not preserved across app installations. To ensure the voice command data for your app remains intact, consider initializing your VCD file each time your app is launched or activated, or maintain a setting that indicates if the VCD is currently installed.

In the "app.xaml.cs" file:

1. Add the following using directive:

```
C#
```

```
using Windows.Storage;
```

2. Mark the "OnLaunched" method with the async modifier.

```
C#

protected async override void OnLaunched(LaunchActivatedEventArgs e)
```

3. Call InstallCommandDefinitionsFromStorageFileAsync in the OnLaunched handler to register the voice commands that the system should recognize.

In the Adventure Works sample, we first define a StorageFile object.

We then call GetFileAsync to initialize it with our "AdventureWorksCommands.xml" file.

This StorageFile object is then passed to InstallCommandDefinitionsFromStorageFileAsync.

```
C#

try
{
  // Install the main VCD.
  StorageFile vcdStorageFile =
  await Package.Current.InstalledLocation.GetFileAsync(
  @"AdventureWorksCommands.xml");

  await
Windows.ApplicationModel.VoiceCommands.VoiceCommandDefinitionManager.
InstallCommandDefinitionsFromStorageFileAsync(vcdStorageFile);

  // Update phrase list.
  ViewModel.ViewModelLocator locator =
App.Current.Resources["ViewModelLocator"] as ViewModel.ViewModelLocator;
  if(locator != null)
  {
     await locator.TripViewModel.UpdateDestinationPhraseList();
  }
}
catch (Exception ex)
{
  System.Diagnostics.Debug.WriteLine("Installing Voice Commands Failed: " +
ex.ToString());
}
```

Handle activation and execute voice commands

Specify how your app responds to subsequent voice command activations (after it has been launched at least once and the voice command sets have been installed).

1. Confirm that your app was activated by a voice command.

Override the Application.OnActivated event and check whether IActivatedEventArgs.Kind is VoiceCommand.

2. Determine the name of the command and what was spoken.

   Get a reference to a VoiceCommandActivatedEventArgs object from the IActivatedEventArgs and query the Result property for a SpeechRecognitionResult object.

   To determine what the user said, check the value of Text or the semantic properties of the recognized phrase in the SpeechRecognitionSemanticInterpretation dictionary.

3. Take the appropriate action in your app, such as navigating to the desired page.

For this example, we refer back to the VCD in Step 3: Edit the VCD file.

Once we get the speech-recognition result for the voice command, we get the command name from the first value in the RulePath array. As the VCD file defined more than one possible voice command, we need to compare the value against the command names in the VCD and take the appropriate action.

The most common action an application can take is to navigate to a page with content relevant to the context of the voice command. For this example, we navigate to a **TripPage** page and pass in the value of the voice command, how the command was input, and the recognized "destination" phrase (if applicable). Alternatively, the app could send a navigation parameter to the SpeechRecognitionResult when navigating to the page.

You can find out whether the voice command that launched your app was actually spoken, or whether it was typed in as text, from the SpeechRecognitionSemanticInterpretation.Properties dictionary using the **commandMode** key. The value of that key will be either "voice" or "text". If the value of the key is "voice", consider using speech synthesis (Windows.Media.SpeechSynthesis) in your app to provide the user with spoken feedback.

Use the SpeechRecognitionSemanticInterpretation.Properties to find out the content spoken in the **PhraseList** or **PhraseTopic** constraints of a **ListenFor** element. The dictionary key is the value of the **Label** attribute of the **PhraseList** or **PhraseTopic** element. Here, we show how to access the value of **{destination}** phrase.

C#

```
/// <summary>
/// Entry point for an application activated by some means other than normal
```

```
launching.
/// This includes voice commands, URI, share target from another app, and so
on.
///
/// NOTE:
/// A previous version of the VCD file might remain in place
/// if you modify it and update the app through the store.
/// Activations might include commands from older versions of your VCD.
/// Try to handle these commands gracefully.
/// </summary>
/// <param name="args">Details about the activation method.</param>
protected override void OnActivated(IActivatedEventArgs args)
{
    base.OnActivated(args);

    Type navigationToPageType;

Dynamically modify Cortana VCD phrase lists

Article • 06/24/2021

> ⚠ **Warning**
>
> This feature is no longer supported as of the Windows 10 May 2020 Update (version 2004, codename "20H1").

Access and update the list of supported phrases (**PhraseList** elements) in a Voice Command Definition (VCD) file at run time using the speech recognition result.

> ⓘ **Note**
>
> A voice command is a single utterance with a specific intent, defined in a Voice Command Definition (VCD) file, directed at an installed app via **Cortana**.
>
> A VCD file defines one or more voice commands, each with a unique intent.
>
> Voice command definitions can vary in complexity. They can support anything from a single, constrained utterance to a collection of more flexible, natural language utterances, all denoting the same intent.

Dynamically modifying a phrase list at run time is useful if the voice command is specific to a task involving some kind of user-defined, or transient, app data.

> ⓘ **Note**
>
> **Important APIs**
>
> - Windows.ApplicationModel.VoiceCommands
> - VCD elements and attributes v1.2

As an example, let's say you have a travel app where users can enter destinations, and you want users to be able to start the app by saying the app name followed by "Show trip to <destination>". In the **ListenFor** element itself, you would specify something like: `<ListenFor> Show trip to {destination} </ListenFor>`, where "destination" is the value of the **Label** attribute for the **PhraseList**.

Updating the phrase list at run time eliminates the need to create a separate **ListenFor** element for each possible destination. Instead, you can dynamically populate **PhraseList** with destinations specified by the user as they enter their itineraries.

For more info about **PhraseList** and other VCD elements, see the **VCD elements and attributes v1.2** reference.

Identify the command and update the phrase list

Here's an example VCD file that defines a **Command** "showTripToDestination" and a **PhraseList** that defines three options for destination in our **Adventure Works** travel app. As the user saves and deletes destinations in the app, the app updates the options in the **PhraseList**.

XML

```
<?xml version="1.0" encoding="utf-8"?>
<VoiceCommands xmlns="https://schemas.microsoft.com/voicecommands/1.1">
  <CommandSet xml:lang="en-us" Name="AdventureWorksCommandSet_en-us">
    <AppName> Adventure Works, </AppName>
    <Example> Show trip to London </Example>

    <Command Name="showTripToDestination">
      <Example> show trip to London  </Example>
      <ListenFor> show trip to {destination} </ListenFor>
      <Feedback> Showing trip to {destination} </Feedback>
      <Navigate/>
```

```
    </Command>

    <PhraseList Label="destination">
      <Item> London </Item>
      <Item> Dallas </Item>
      <Item> New York </Item>
    </PhraseList>

  </CommandSet>

<!-- Other CommandSets for other languages -->

</VoiceCommands>
```

To update a **PhraseList** element in the VCD file, get the **CommandSet** element that contains the phrase list. Use the **Name** attribute of that **CommandSet** element (**Name** must be unique in the VCD file) as a key to access the VoiceCommandManager.InstalledCommandSets property and get the VoiceCommandSet reference.

After you've identified the command set, get a reference to the phrase list that you want to modify and call the SetPhraseListAsync method; use the **Label** attribute of the **PhraseList** element and an array of strings as the new content of the phrase list.

> **Note**
>
> If you modify a phrase list, the entire phrase list is replaced. If you want to insert new items into a phrase list, you must specify both the existing items and the new items in the call to SetPhraseListAsync.

In this example, we update the **PhraseList** shown in the previous example with an additional destination to Phoenix.

CSharp

```
Windows.ApplicationModel.VoiceCommands.VoiceCommandDefinition.VoiceCommandSe
t commandSetEnUs;

if (Windows.ApplicationModel.VoiceCommands.VoiceCommandDefinitionManager.
      InstalledCommandSets.TryGetValue(
        "AdventureWorksCommandSet_en-us", out commandSetEnUs))
{
  await commandSetEnUs.SetPhraseListAsync(
    "destination", new string[] {"London", "Dallas", "New York",
"Phoenix"});
}
```

Remarks

Using a **PhraseList** to constrain the recognition is appropriate for a relatively small set or words. When the set of words is too large (hundreds of words, for example), or shouldn't be constrained at all, use the **PhraseTopic** element and a **Subject** element to refine the relevance of speech-recognition results to improve scalability.

In our example, we have a **PhraseTopic** with a **Scenario** of "Search", further refined by a **Subject** of "City\State".

XML

```
<?xml version="1.0" encoding="utf-8"?>
<VoiceCommands xmlns="https://schemas.microsoft.com/voicecommands/1.1">
  <CommandSet xml:lang="en-us" Name="AdventureWorksCommandSet_en-us">
    <AppName> Adventure Works, </AppName>
    <Example> Show trip to London </Example>

    <Command Name="showTripToDestination">
      <Example> show trip to London  </Example>
      <ListenFor> show trip to {destination} </ListenFor>
      <Feedback> Showing trip to {destination} </Feedback>
      <Navigate/>
    </Command>

    <PhraseList Label="destination">
      <Item> London </Item>
      <Item> Dallas </Item>
      <Item> New York </Item>
    </PhraseList>

    <PhraseTopic Label="destination" Scenario="Search">
      <Subject>City/State</Subject>
    </PhraseTopic>

  </CommandSet>
```

Activate a background app in Cortana using voice commands

Article • 06/24/2021

> ⚠ **Warning**
>
> This feature is no longer supported as of the Windows 10 May 2020 Update (version 2004, codename "20H1").

In addition to using voice commands within **Cortana** to access system features, you may also extend **Cortana** with features and functionality from your app (as a background task) using voice commands that specify an action or command to run. When an app handles a voice command in the background, it does not take focus. Instead, it returns all feedback and results through the **Cortana** canvas and the **Cortana** voice.

> ⓘ **Note**
>
> **Important APIs**
>
> - Windows.ApplicationModel.VoiceCommands
> - VCD elements and attributes v1.2

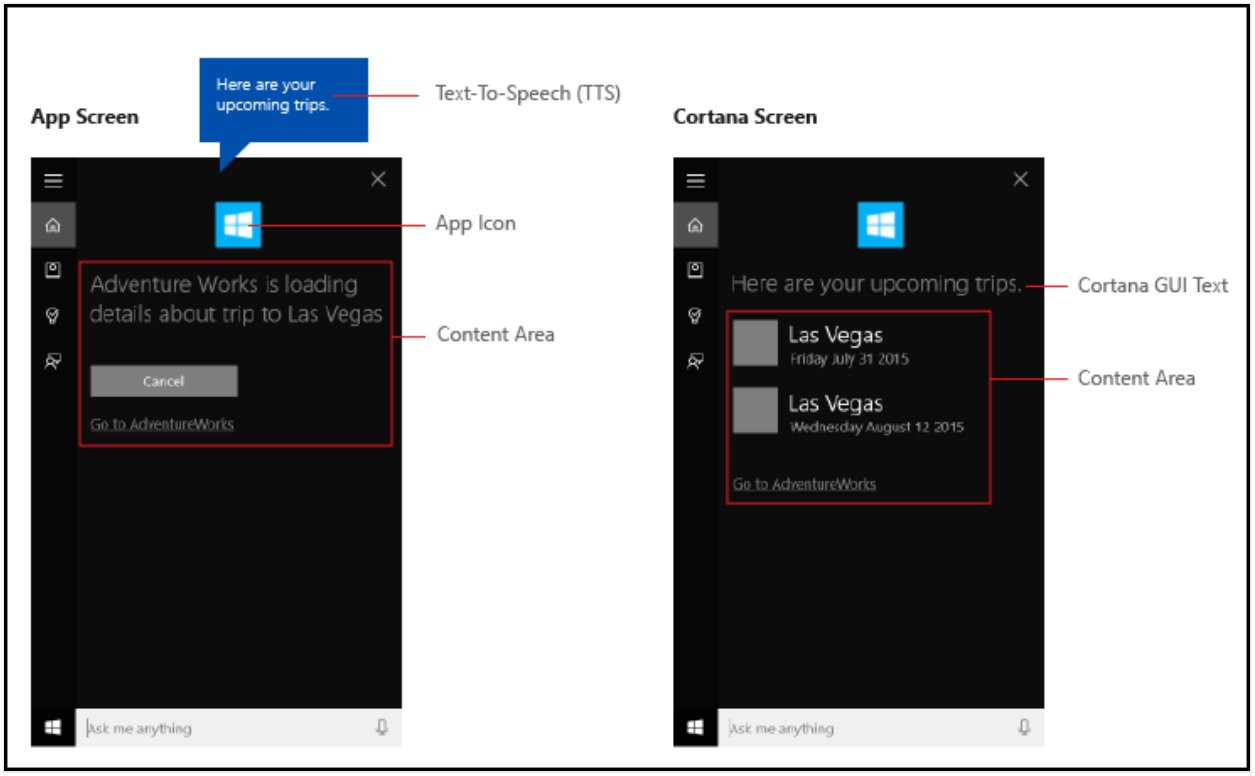
Apps may be activated to the foreground (the app takes focus) or activated in the background (**Cortana** retains focus), depending on the complexity of the interaction. For example, voice commands that require additional context or user input (such as sending a message to a specific contact) are best handled in a foreground app, while basic commands (such as listing upcoming trips) may be handled in **Cortana** through a background app.

If you want to activate an app to the foreground using voice commands, see Activate a foreground app with voice commands through Cortana.

> ⓘ **Note**
>
> A voice command is a single utterance with a specific intent, defined in a Voice Command Definition (VCD) file, directed at an installed app via **Cortana**.
>
> A VCD file defines one or more voice commands, each with a unique intent.

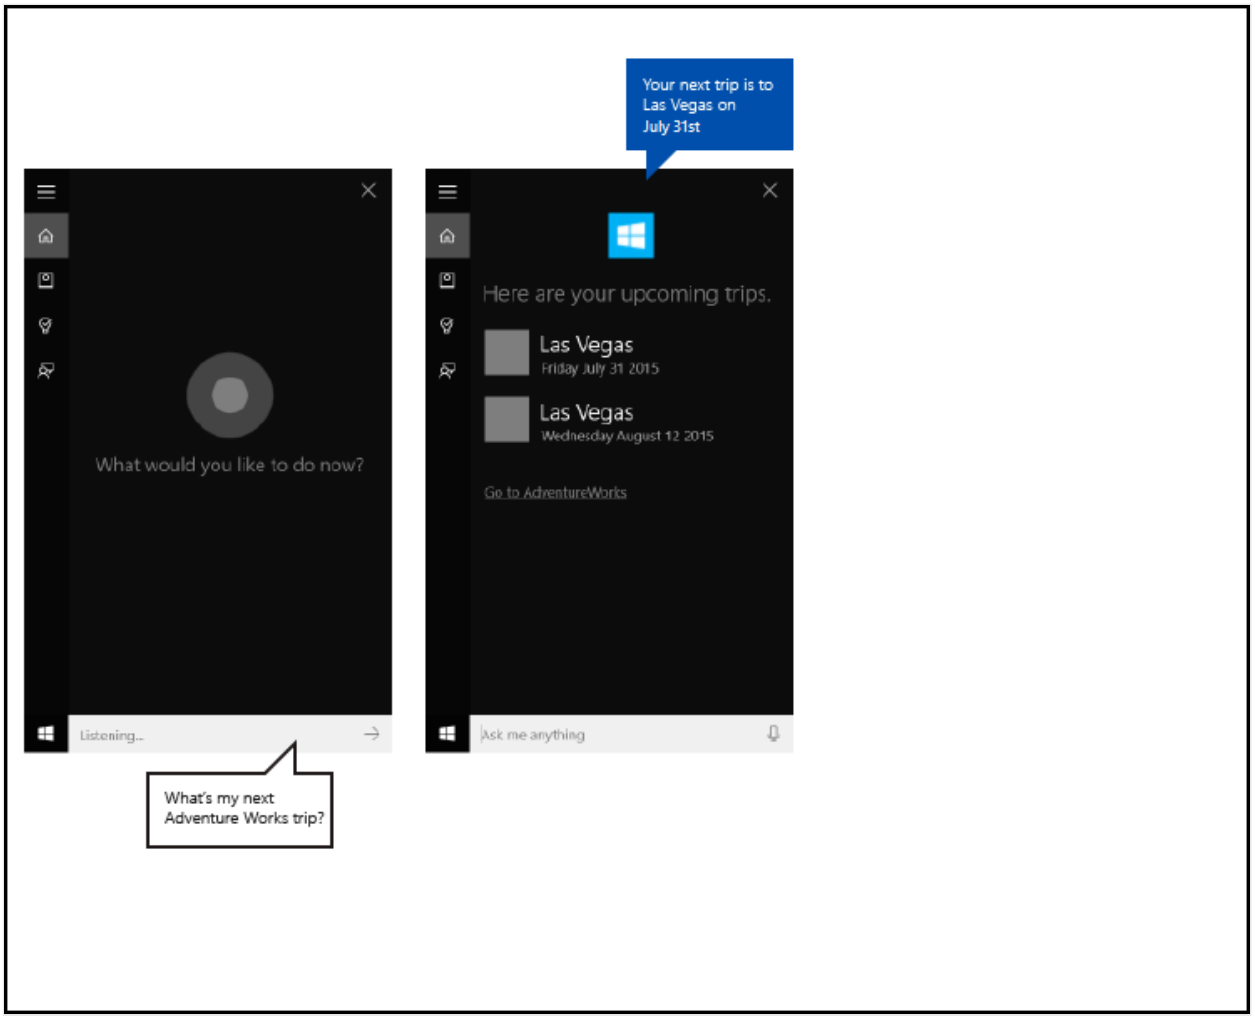
Voice command definitions can vary in complexity. They can support anything from a single, constrained utterance to a collection of more flexible, natural language utterances, all denoting the same intent.

We use a trip planning and management app named **Adventure Works** integrated into the **Cortana** UI, shown here, to demonstrate many of the concepts and features we discuss. For more info, see the Cortana voice command sample.



To view an **Adventure Works** trip without **Cortana**, a user would launch the app and navigate to the **Upcoming trips** page.

Using voice commands through **Cortana** to launch your app in the background, the user may instead just say, `Adventure Works, when is my trip to Las Vegas?`. Your app handles the command and **Cortana** displays results along with your app icon and other app info, if provided.



The following basic steps add voice-command functionality and extend **Cortana** with background functionality from your app using speech or keyboard input.

1. Create an app service (see **Windows.ApplicationModel.AppService**) that **Cortana** invokes in the background.
2. Create a VCD file. The VCD file is an XML document that defines all the spoken commands that the user may say to initiate actions or invoke commands when activating your app. See **VCD elements and attributes v1.2**.
3. Register the command sets in the VCD file when the app is launched.
4. Handle the background activation of the app service and the running of the voice command.
5. Display and speak the appropriate feedback to the voice command within **Cortana**.

Tip

Prerequisites

If you're new to developing Universal Windows Platform (UWP) apps, have a look through these topics to get familiar with the technologies discussed here.

- Create your first app

- Learn about events with **Events and routed events overview**

User experience guidelines

See **Cortana design guidelines** for info about how to integrate your app with **Cortana** and **Speech interactions** for helpful tips on designing a useful and engaging speech-enabled app.

Create a New Solution with a Primary Project in Visual Studio

1. Launch Microsoft Visual Studio 2015.
   The Visual Studio 2015 Start page appears.

2. On the **File** menu, select **New** > **Project**.
   The **New Project** dialog appears. The left pane of the dialog lets you select the type of templates to display.

3. In the left pane, expand **Installed** > **Templates** > **Visual C#** > **Windows**, then pick the **Universal** template group. The center pane of the dialog displays a list of project templates for Universal Windows Platform (UWP) apps.

4. In the center pane, select the **Blank App (Universal Windows)** template.
   The **Blank App** template creates a minimal UWP app that compiles and runs. The **Blank App** template includes no user-interface controls or data. You add controls to the app using this page as a guide.

5. In the **Name** text box, type your project name. Example: Use `AdventureWorks`.

6. Click on the **OK** button to create the project.
   Microsoft Visual Studio creates your project and displays it in the **Solution Explorer**.

Add Image Assets to Primary Project and Specify them in the App Manifest

UWP apps should automatically select the most appropriate images. The selection is based upon specific settings and device capabilities (high contrast, effective pixels, locale, and so on). You must provide the images and ensure that you use the appropriate naming convention and folder organization within your app project for the different resource versions.

If you do not provide the recommended resource versions, then the user experience may suffer in the following ways.

- Accessibility
- Localization
- Image quality
  The resource versions are used to adapt the following changes in the user experience.
- User preferences
- Abilities
- Device type
- Location

For more detail about image resources for high contrast and scale factors, visit the Guidelines for tile and icon assets page located at msdn.microsoft.com/windows/uwp/controls-and-patterns/tiles-and-notifications-app-assets.

You must name resources using qualifiers. Resource qualifiers are folder and filename modifiers that identify the context in which a particular version of a resource should be used.

The standard naming convention is `foldername/qualifiername-value[_qualifiername-value]/filename.qualifiername-value[_qualifiername-value].ext`.
Example: `images/logo.scale-100_contrast-white.png`, which may refer to code using just the root folder and the filename: `images/logo.png`.
For more information, visit the How to name resources using qualifiers page located at msdn.microsoft.com/library/windows/apps/xaml/hh965324.aspx.

Microsoft recommends that you mark the default language on string resource files (such as `en-US\resources.resw`) and the default scale factor on images (such as `logo.scale-100.png`), even if you do not currently plan to provide localized or multiple resolution resources. However, at a minimum, Microsoft recommends that you provide assets for 100, 200, and 400 scale factors.

> **ⓘ Important**
>
> The app icon used in the title area of the **Cortana** canvas is the Square44x44Logo icon specified in the `Package.appxmanifest` file.
> You may also specify an icon for each entry in the content area of the **Cortana** canvas. Valid image sizes for the results icons are:

- 68w x 68h
- 68w x 92h
- 280w x 140h

The content tile is not validated until a VoiceCommandResponse object is passed to the VoiceCommandServiceConnection class. If you pass a VoiceCommandResponse object to **Cortana** that includes a content tile with an image that does not adhere to these size ratios, then an exception may occur.

Example: The **Adventure Works** app (`VoiceCommandService\\AdventureWorksVoiceCommandService.cs`) specifies a simple, grey square (`GreyTile.png`) on the VoiceCommandContentTile class using the TitleWith68x68IconAndText tile template. The logo variants are located in `VoiceCommandService\\Images`, and are retrieved using the GetFileFromApplicationUriAsync method.

C#

```
var destinationTile = new VoiceCommandContentTile();

destinationTile.ContentTileType =
VoiceCommandContentTileType.TitleWith68x68IconAndText;
destinationTile.Image = await StorageFile.GetFileFromApplicationUriAsync(
    new Uri("ms-appx:///AdventureWorks.VoiceCommands/Images/GreyTile.png")
);
```

Create an App Service Project

1. Right-click on your Solution name, select **New** > **Project**.
2. Under **Installed** > **Templates** > **Visual C#** > **Windows** > **Universal**, select **Windows Runtime Component**. The **Windows Runtime Component** is the component that implements the app service (Windows.ApplicationModel.AppService).
3. Type a name for the project and click on the **OK** button.
   Example: `VoiceCommandService`.
4. In **Solution Explorer**, select the `VoiceCommandService` project and rename the `Class1.cs` file generated by Visual Studio. Example: The **Adventure Works** uses `AdventureWorksVoiceCommandService.cs`.

5. Click on the **Yes** button; when asked if you want to rename all occurrences of `Class1.cs`.

6. In the `AdventureWorksVoiceCommandService.cs` file:
   a. Add the following using directive.
   `using Windows.ApplicationModel.Background;`
   b. When you create a new project, the project name is used as the default root namespace in all files. Rename the namespace to nest the app service code under the primary project. Example: `namespace AdventureWorks.VoiceCommands`.
   c. Right-click on the app service project name in Solution Explorer and select **Properties**.
   d. On the **Library** tab, update the **Default namespace** field with this same value. Example: `AdventureWorks.VoiceCommands`).
   e. Create a new class that implements the **IBackgroundTask** interface. This class requires a **Run** method, which is the entry point when Cortana recognizes the voice command.

Example: A basic background task class from the **Adventure Works** app.

> **Note**
>
> The background task class itself, as well as all classes in the background task project, must be sealed public classes.

C#

```
namespace AdventureWorks.VoiceCommands
{
    ...

    /// <summary>
    /// The VoiceCommandService implements the entry point for all
voice commands.
    /// The individual commands supported are described in the VCD xml
file.
    /// The service entry point is defined in the appxmanifest.
    /// </summary>
    public sealed class AdventureWorksVoiceCommandService :
IBackgroundTask
    {
        ...

        /// <summary>
        /// The background task entrypoint.
        ///
        /// Background tasks must respond to activation by Cortana
```

```
within 0.5 second, and must
        /// report progress to Cortana every 5 seconds (unless Cortana
is waiting for user
        /// input). There is no running time limit on the background
task managed by Cortana,
        /// but developers should use plmdebug
(https://msdn.microsoft.com/library/windows/hardware/jj680085%28v=vs.85
%29.aspx)
        /// on the Cortana app package in order to prevent Cortana
timing out the task during
        /// debugging.
        ///
        /// The Cortana UI is dismissed if Cortana loses focus.
        /// The background task is also dismissed even if being
debugged.
        /// Use of Remote Debugging is recommended in order to debug
background task behaviors.
        /// Open the project properties for the app package (not the
background task project),
        /// and enable Debug -> "Do not launch, but debug my code when
it starts".
        /// Alternatively, add a long initial progress screen, and
attach to the background task process while it runs.
        /// </summary>
        /// <param name="taskInstance">Connection to the hosting
background service process.</param>
        public void Run(IBackgroundTaskInstance taskInstance)
        {
          //
          // TODO: Insert code
          //
          //
    }
  }
}
```

7. Declare your background task as an **AppService** in the app manifest.
   a. In **Solution Explorer**, right-click on the `Package.appxmanifest` file and select **View Code**.
   b. Find the Application element.
   c. Add an Extensions element to the Application element.
   d. Add a uap:Extension element to the Extensions element.
   e. Add a `Category` attribute to the `uap:Extension` element and set the value of the `Category` attribute to `windows.appService`.
   f. Add an `EntryPoint` attribute to the `uap: Extension` element and set the value of the `EntryPoint` attribute to the name of the class that implements IBackgroundTask.
   Example: `AdventureWorks.VoiceCommands.AdventureWorksVoiceCommandService`.
   g. Add a uap:AppService element to the `uap:Extension` element.

h. Add a `Name` attribute to the uap:AppService element and set the value of the `Name` attribute to a name for the app service, in this case `AdventureWorksVoiceCommandService`.
i. Add a second uap:Extension element to the Extensions element.
j. Add a `Category` attribute to this uap:Extension element and set the value of the `Category` attribute to `windows.personalAssistantLaunch`.

Example: A manifest from the Adventure Works app.

XML

```
<Package>
    <Applications>
        <Application>

            <Extensions>
                <uap:Extension Category="windows.appService"
EntryPoint="CortanaBack1.VoiceCommands.AdventureWorksVoiceCommandServic
e">
                    <uap:AppService
Name="AdventureWorksVoiceCommandService"/>
                </uap:Extension>
                <uap:Extension
Category="windows.personalAssistantLaunch"/>
            </Extensions>

        <Application>
    <Applications>
</Package>
```

8. Add this app service project as a reference in the primary project.
   a. Right-click on the **References**.
   b. Select **Add Reference...**.
   c. In the **Reference Manager** dialog, expand **Projects** and select the app service project.
   d. Click on the **OK** button.

Create a VCD File

1. In Visual Studio, right-click on your primary project name, select **Add** > **New Item**. Add an **XML File**.
2. Type a name for the VCD file.
   Example: `AdventureWorksCommands.xml`.
3. Click on the **Add** button.
4. In **Solution Explorer**, select the VCD file.

5. In the **Properties** window, set **Build action** to **Content**, and then set **Copy to output directory** to **Copy if newer**.

Edit the VCD File

1. Add a `VoiceCommands` element with an `xmlns` attribute pointing to `https://schemas.microsoft.com/voicecommands/1.2`.

2. For each language supported by your app, create a CommandSet element that includes the voice commands supported by your app.
   You are able to declare multiple CommandSet elements, each with a different xml:lang attribute so your app to be used in different markets. For example, an app for the United States might have a CommandSet for English and a CommandSet for Spanish.

   > **ⓘ Important**
   >
   > To activate an app and initiate an action using a voice command, the app must register a VCD file that includes a **CommandSet** element with a language that matches the speech language indicated in the device of the user. The speech language is located in **Settings** > **System** > **Speech** > **Speech Language**.

3. Add a `Command` element for each command you want to support.
   Each `Command` declared in a **VCD** file must include this information:

   - A `Name` attribute that your application uses to identify the voice command at runtime.
   - An `Example` element that includes a phrase describing how a user invokes the command. **Cortana** shows the example when the user says `What can I say?`, `Help`, or taps **See more**.
   - A `ListenFor` element that includes the words or phrases that your app recognizes as a command. Each `ListenFor` element may contain references to one or more `PhraseList` elements that contain specific words relevant to the command.

     > **ⓘ Note**

> `ListenFor` elements must not be programmatically modified. However, `PhraseList` elements associated with `ListenFor` elements may be programmatically modified. Applications should modify the content of the `PhraseList` element at runtime based on the data set generated as the user uses the app.
>
> For more information, see Dynamically modify Cortana VCD phrase lists.

- A `Feedback` element that includes the text for **Cortana** to display and speak as the application is launched.

A `Navigate` element indicates that the voice command activates the app to the foreground. In this example, the `showTripToDestination` command is a foreground task.

A `VoiceCommandService` element indicates that the voice command activates the app in the background. The value of the `Target` attribute of this element should match the value of the `Name` attribute of the uap:AppService element in the package.appxmanifest file. In this example, the `whenIsTripToDestination` and `cancelTripToDestination` commands are background tasks that specify the name of the app service as `AdventureWorksVoiceCommandService`.

For more detail, see the **VCD elements and attributes v1.2** reference.

Example: A portion of the **VCD** file that defines the `en-us` voice commands for the **Adventure Works** app.

XML

```
<?xml version="1.0" encoding="utf-8" ?>
<VoiceCommands xmlns="https://schemas.microsoft.com/voicecommands/1.2">
<CommandSet xml:lang="en-us" Name="AdventureWorksCommandSet_en-us">
    <AppName> Adventure Works </AppName>
    <Example> Show trip to London </Example>

    <Command Name="showTripToDestination">
        <Example> Show trip to London </Example>
        <ListenFor RequireAppName="BeforeOrAfterPhrase"> show [my] trip to
{destination} </ListenFor>
        <ListenFor RequireAppName="ExplicitlySpecified"> show [my]
{builtin:AppName} trip to {destination} </ListenFor>
        <Feedback> Showing trip to {destination} </Feedback>
        <Navigate />
    </Command>

    <Command Name="whenIsTripToDestination">
```

```
        <Example> When is my trip to Las Vegas?</Example>
        <ListenFor RequireAppName="BeforeOrAfterPhrase"> when is [my] trip
to {destination}</ListenFor>
        <ListenFor RequireAppName="ExplicitlySpecified"> when is [my]
{builtin:AppName} trip to {destination} </ListenFor>
        <Feedback> Looking for trip to {destination}</Feedback>
        <VoiceCommandService Target="AdventureWorksVoiceCommandService"/>
    </Command>

    <Command Name="cancelTripToDestination">
        <Example> Cancel my trip to Las Vegas </Example>
        <ListenFor RequireAppName="BeforeOrAfterPhrase"> cancel [my] trip to
{destination}</ListenFor>
        <ListenFor RequireAppName="ExplicitlySpecified"> cancel [my]
{builtin:AppName} trip to {destination} </ListenFor>
        <Feedback> Cancelling trip to {destination}</Feedback>
        <VoiceCommandService Target="AdventureWorksVoiceCommandService"/>
    </Command>

    <PhraseList Label="destination">
        <Item>London</Item>
        <Item>Las Vegas</Item>
        <Item>Melbourne</Item>
        <Item>Yosemite National Park</Item>
    </PhraseList>
</CommandSet>
```

Install the VCD Commands

Your app must run once to install the VCD.

> ⓘ **Note**
>
> Voice command data is not preserved across app installations. To ensure the voice command data for your app remains intact, consider initializing your VCD file each time your app is launched or activated, or maintain a setting that indicates if the VCD is currently installed.

In the `app.xaml.cs` file:

1. Add the following using directive:

   C#

   ```
   using Windows.Storage;
   ```

2. Mark the `OnLaunched` method with the async modifier.

C#

```
protected async override void OnLaunched(LaunchActivatedEventArgs e)
```

3. Call the InstallCommandDefinitionsFromStorageFileAsync method in the OnLaunched handler to register the voice commands that should be recognized.
   Example: The Adventure Works app defines a StorageFile object.
   Example: Call the GetFileAsync method to initialize the StorageFile object with the `AdventureWorksCommands.xml` file.
   The StorageFile object is then passed to InstallCommandDefinitionsFromStorageFileAsync method.

C#

```
try {
   // Install the main VCD.
   StorageFile vcdStorageFile = await
Package.Current.InstalledLocation.GetFileAsync(
         @"AdventureWorksCommands.xml"
   );

   await
Windows.ApplicationModel.VoiceCommands.VoiceCommandDefinitionManager.In
stallCommandDefinitionsFromStorageFileAsync(vcdStorageFile);

   // Update phrase list.
   ViewModel.ViewModelLocator locator =
App.Current.Resources["ViewModelLocator"] as
ViewModel.ViewModelLocator;
   if(locator != null) {
         await locator.TripViewModel.UpdateDestinationPhraseList();
     }
 }
 catch (Exception ex) {
     System.Diagnostics.Debug.WriteLine("Installing Voice Commands
Failed: " + ex.ToString());
 }
```

Handle Activation

Specify how your app responds to subsequent voice command activations.

> **Note**

You must launch your app at least once after the voice command sets have been installed.

1. Confirm that your app was activated by a voice command.

   Override the Application.OnActivated event and check whether **IActivatedEventArgs**.**Kind** is **VoiceCommand**.

2. Determine the name of the command and what was spoken.

   Get a reference to a VoiceCommandActivatedEventArgs object from the **IActivatedEventArgs** and query the Result property for a SpeechRecognitionResult object.

   To determine what the user said, check the value of **Text** or the semantic properties of the recognized phrase in the SpeechRecognitionSemanticInterpretation dictionary.

3. Take the appropriate action in your app, such as navigating to the desired page.

   > **Note**
   >
   > If you need to refer to your VCD, visit the **Edit the VCD File** section.

   After receiving the speech-recognition result for the voice command, you get the command name from the first value in the RulePath array. Since the VCD file defines more than one possible voice command, you must verify that the value matches the command names in the VCD and take the appropriate action.

   The most common action for an application is to navigate to a page with content relevant to the context of the voice command.
   Example: Open the **TripPage** page and pass in the value of the voice command, how the command was input, and the recognized destination phrase (if applicable). Alternatively, the app may send a navigation parameter to the **SpeechRecognitionResult** when navigating to the **TripPage** page.

   You are able to find out whether the voice command that launched your app was actually spoken, or whether it was typed in as text, from the SpeechRecognitionSemanticInterpretation.Properties dictionary using the **commandMode** key. The value of that key will be either `voice` or `text`. If the value of the key is `voice`, consider using speech synthesis (**Windows.Media.SpeechSynthesis**) in your app to provide the user with spoken feedback.

Use the SpeechRecognitionSemanticInterpretation.Properties to find out the content spoken in the `PhraseList` or `PhraseTopic` constraints of a `ListenFor` element. The dictionary key is the value of the `Label` attribute of the `PhraseList` or `PhraseTopic` element. Example: The following code for How to access the value of **{destination}** phrase.

C#

```
/// <summary>
/// Entry point for an application activated by some means other than
normal launching.
/// This includes voice commands, URI, share target from another app,
and so on.
///
/// NOTE:
/// A previous version of the VCD file might remain in place
/// if you modify it and update the app through the store.
/// Activations might include commands from older versions of your VCD.
/// Try to handle these commands gracefully.
/// </summary>
/// <param name="args">Details about the activation method.</param>
protected override void OnActivated(IActivatedEventArgs args) {
    base.OnActivated(args);

    Type navigationToPageType;
    ViewModel.TripVoiceCommand? navigationCommand = null;

    // Voice command activation.
    if (args.Kind == ActivationKind.VoiceCommand) {
        // Event args may represent many different activation types.
        // Cast the args so that you only get useful parameters out.
        var commandArgs = args as VoiceCommandActivatedEventArgs;

        Windows.Media.SpeechRecognition.SpeechRecognitionResult
speechRecognitionResult = commandArgs.Result;

        // Get the name of the voice command and the text spoken.
        // See VoiceCommands.xml for supported voice commands.
        string voiceCommandName = speechRecognitionResult.RulePath[0];
        string textSpoken = speechRecognitionResult.Text;

        // commandMode indicates whether the command was entered using
speech or text.
        // Apps should respect text mode by providing silent (text)
feedback.
        string commandMode = this.SemanticInterpretation("commandMode",
speechRecognitionResult);

        switch (voiceCommandName) {
            case "showTripToDestination":
                // Access the value of {destination} in the voice
command.
```

```
                string destination =
this.SemanticInterpretation("destination", speechRecognitionResult);

                // Create a navigation command object to pass to the
page.
                navigationCommand = new ViewModel.TripVoiceCommand(
                    voiceCommandName,
                    commandMode,
                    textSpoken,
                    destination
                );

                // Set the page to navigate to for this voice command.
                navigationToPageType = typeof(View.TripDetails);
                break;
            default:
                // If not able to determine what page to launch, then
go to the default entry point.
                navigationToPageType = typeof(View.TripListView);
                break;
        }
    }
    // Protocol activation occurs when a card is selected within
Cortana (using a background task).
    else if (args.Kind == ActivationKind.Protocol) {
        // Extract the launch context. In this case, use the
destination from the phrase set (passed
        // along in the background task inside Cortana), which makes no
attempt to be unique. A unique id or
        // identifier is ideal for more complex scenarios. The
destination page is left to check if the
        // destination trip still exists, and navigate back to the trip
list if it does not.
        var commandArgs = args as ProtocolActivatedEventArgs;
        Windows.Foundation.WwwFormUrlDecoder decoder = new
Windows.Foundation.WwwFormUrlDecoder(commandArgs.Uri.Query);
        var destination = decoder.GetFirstValueByName("LaunchContext");

        navigationCommand = new ViewModel.TripVoiceCommand(
            "protocolLaunch",
            "text",
            "destination",
            destination
        );

        navigationToPageType = typeof(View.TripDetails);
    }
    else {
        // If launched using any other mechanism, fall back to the main
page view.
        // Otherwise, the app will freeze at a splash screen.
        navigationToPageType = typeof(View.TripListView);
    }

    // Repeat the same basic initialization as OnLaunched() above,
```

```
taking into account whether
    // or not the app is already active.
    Frame rootFrame = Window.Current.Content as Frame;

    // Do not repeat app initialization when the Window already has
content,
    // just ensure that the window is active.
    if (rootFrame == null) {
        // Create a frame to act as the navigation context and navigate
to the first page.
        rootFrame = new Frame();
        App.NavigationService = new NavigationService(rootFrame);

        rootFrame.NavigationFailed += OnNavigationFailed;

        // Place the frame in the current window.
        Window.Current.Content = rootFrame;
    }

    // Since the expectation is to always show a details page, navigate
even if
    // a content frame is in place (unlike OnLaunched).
    // Navigate to either the main trip list page, or if a valid voice
command
    // was provided, to the details page for that trip.
    rootFrame.Navigate(navigationToPageType, navigationCommand);

    // Ensure the current window is active
    Window.Current.Activate();
}

/// <summary>
/// Returns the semantic interpretation of a speech result.
/// Returns null if there is no interpretation for that key.
/// </summary>
/// <param name="interpretationKey">The interpretation key.</param>
/// <param name="speechRecognitionResult">The speech recognition result
to get the semantic interpretation from.</param>
/// <returns></returns>
private string SemanticInterpretation(string interpretationKey,
SpeechRecognitionResult speechRecognitionResult) {
    return
speechRecognitionResult.SemanticInterpretation.Properties[interpretatio
nKey].FirstOrDefault();
}
```

Handle the Voice Command in the App Service

Process the voice command in the app service.

1. Add the following using directives to your voice command service file.
   Example: `AdventureWorksVoiceCommandService.cs`.

   C#

   ```
   using Windows.ApplicationModel.VoiceCommands;
   using Windows.ApplicationModel.Resources.Core;
   using Windows.ApplicationModel.AppService;
   ```

2. Take a service deferral so your app service is not terminated while handling the voice command.

3. Confirm that your background task is running as an app service activated by a voice command.
   a. Cast the **IBackgroundTaskInstance.TriggerDetails** to **Windows.ApplicationModel.AppService.AppServiceTriggerDetails**.
   b. Check that **IBackgroundTaskInstance.TriggerDetails.Name** is the name of the app service in the `Package.appxmanifest` file.

4. Use **IBackgroundTaskInstance.TriggerDetails** to create a **VoiceCommandServiceConnection** to **Cortana** to retrieve the voice command.

5. Register an event handler for **VoiceCommandServiceConnection**. **VoiceCommandCompleted** to receive notification when the app service is closed due to a user cancellation.

6. Register an event handler for the **IBackgroundTaskInstance.Canceled** to receive notification when the app service is closed due to an unexpected failure.

7. Determine the name of the command and what was spoken.
   a. Use the **VoiceCommand.CommandName** property to determine the name of the voice command.
   b. To determine what the user said, check the value of **Text** or the semantic properties of the recognized phrase in the SpeechRecognitionSemanticInterpretation dictionary.

8. Take the appropriate action in your app service.

9. Display and speak the feedback to the voice command using **Cortana**.
   a. Determine the strings that you want **Cortana** to display and speak to the user in response to the voice command and create a VoiceCommandResponse object. For guidance on how to select the feedback strings that **Cortana** shows and speaks, see Cortana design guidelines.

b. Use the VoiceCommandServiceConnection instance to report progress or completion to **Cortana** by calling ReportProgressAsync or ReportSuccessAsync with the `VoiceCommandServiceConnection` object.

> **Note**
>
> If you need to refer to your VCD, visit the Edit the VCD File section.

C#

```
public sealed class VoiceCommandService : IBackgroundTask {
    private BackgroundTaskDeferral serviceDeferral;
    VoiceCommandServiceConnection voiceServiceConnection;

    public async void Run(IBackgroundTaskInstance taskInstance) {
        //Take a service deferral so the service isn&#39;t terminated.
        this.serviceDeferral = taskInstance.GetDeferral();

        taskInstance.Canceled += OnTaskCanceled;

        var triggerDetails = taskInstance.TriggerDetails as
AppServiceTriggerDetails;

        if (triggerDetails != null &amp;&amp;
            triggerDetails.Name ==
"AdventureWorksVoiceServiceEndpoint") {
            try {
                voiceServiceConnection =

VoiceCommandServiceConnection.FromAppServiceTriggerDetails(
                    triggerDetails);
                voiceServiceConnection.VoiceCommandCompleted +=
                VoiceCommandCompleted;

                VoiceCommand voiceCommand = await
                voiceServiceConnection.GetVoiceCommandAsync();

                switch (voiceCommand.CommandName) {
                    case "whenIsTripToDestination":
                        {
                            var destination =
                            voiceCommand.Properties["destination"][0];

SendCompletionMessageForDestination(destination);
                            break;
                        }

                        // As a last resort, launch the app in the
foreground.
                    default:
                        LaunchAppInForeground();
```

```
                    break;
                }
            }
            finally {
                if (this.serviceDeferral != null) {
                    // Complete the service deferral.
                    this.serviceDeferral.Complete();
                }
            }
        }
    }

    private void VoiceCommandCompleted(VoiceCommandServiceConnection
sender,
        VoiceCommandCompletedEventArgs args) {
        if (this.serviceDeferral != null) {
            // Insert your code here.
            // Complete the service deferral.
            this.serviceDeferral.Complete();
        }
    }

    private async void SendCompletionMessageForDestination(
        string destination) {
        // Take action and determine when the next trip to destination
        // Insert code here.

        // Replace the hardcoded strings used here with strings
        // appropriate for your application.

        // First, create the VoiceCommandUserMessage with the strings
        // that Cortana will show and speak.
        var userMessage = new VoiceCommandUserMessage();
        userMessage.DisplayMessage = "Here's your trip.";
        userMessage.SpokenMessage = "Your trip to Vegas is on August
3rd.";

        // Optionally, present visual information about the answer.
        // For this example, create a VoiceCommandContentTile with an
        // icon and a string.
        var destinationsContentTiles = new
List<VoiceCommandContentTile>();

        var destinationTile = new VoiceCommandContentTile();
        destinationTile.ContentTileType =
            VoiceCommandContentTileType.TitleWith68x68IconAndText;
        // The user taps on the visual content to launch the app.
        // Pass in a launch argument to enable the app to deep link to
a
        // page relevant to the item displayed on the content tile.
        destinationTile.AppLaunchArgument =
            string.Format("destination={0}", "Las Vegas");
        destinationTile.Title = "Las Vegas";
        destinationTile.TextLine1 = "August 3rd 2015";
        destinationsContentTiles.Add(destinationTile);
```

```
        // Create the VoiceCommandResponse from the userMessage and
list
        // of content tiles.
        var response = VoiceCommandResponse.CreateResponse(
            userMessage, destinationsContentTiles);

        // Cortana displays a "Go to app_name" link that the user
        // taps to launch the app.
        // Pass in a launch to enable the app to deep link to a page
        // relevant to the voice command.
        response.AppLaunchArgument = string.Format(
            "destination={0}", "Las Vegas");

        // Ask Cortana to display the user message and content tile and
        // also speak the user message.
        await voiceServiceConnection.ReportSuccessAsync(response);
    }

    private async void LaunchAppInForeground() {
        var userMessage = new VoiceCommandUserMessage();
        userMessage.SpokenMessage = "Launching Adventure Works";

        var response =
VoiceCommandResponse.CreateResponse(userMessage);

        // When launching the app in the foreground, pass an app
        // specific launch parameter to indicate what page to show.
        response.AppLaunchArgument = "showAllTrips=true";

        await voiceServiceConnection.RequestAppLaunchAsync(response);
    }
}
```

Once activated, the app service has 0.5 second to call ReportSuccessAsync. **Cortana** shows and says a feedback string.

> **Note**
>
> You are able to declare a **Feedback** string in the VCD file. The string does not affect the UI text displayed on the Cortana canvas, it only affects the text spoken by **Cortana**.

If the app takes longer than 0.5 second to make the call, **Cortana** inserts a hand-off screen, as shown here. **Cortana** displays the hand-off screen until the application calls **ReportSuccessAsync**, or for up to 5 seconds. If the app service does not call **ReportSuccessAsync**, or any of the VoiceCommandServiceConnection methods that provide **Cortana** with information, the user receives an error message and the app service is canceled.

Interact with a background app in Cortana

Article • 06/24/2021

> ⚠ **Warning**
>
> This feature is no longer supported as of the Windows 10 May 2020 Update (version 2004, codename "20H1").

Enable user interaction with a background app, through speech and text input in the **Cortana** canvas, while executing a voice command.

> ⓘ **Note**
>
> **Important APIs**
>
> - Windows.ApplicationModel.VoiceCommands
> - VCD elements and attributes v1.2

Cortana supports a complete turn-by-turn workflow with your app. This workflow is defined by your app, and can support functionality such as:

- Successful completion
- Hand-off
- Progress
- Confirmation
- Disambiguation
- Error

Composing feedback strings

> 💡 **Tip**
>
> **Prerequisites**
>
> If you're new to developing Universal Windows Platform (UWP) apps, have a look through these topics to get familiar with the technologies discussed here.
>
> - Create your first app

- Learn about events with **Events and routed events overview**

User experience guidelines

See **Cortana design guidelines** for info about how to integrate your app with **Cortana** and **Speech interactions** for helpful tips on designing a useful and engaging speech-enabled app.

Compose the feedback strings that are both displayed and spoken by **Cortana**.

The Cortana design guidelines provides recommendations on composing strings for **Cortana**.

Content cards can provide additional context for the user and help you keep feedback strings concise.

Cortana supports the following content card templates (only one template can be used on the completion screen):

- Title only
- Title with up to three lines of text
- Title with image
- Title with image and up to three lines of text

The image can be:

- 68w x 68h
- 68w x 92h
- 280w x 140h

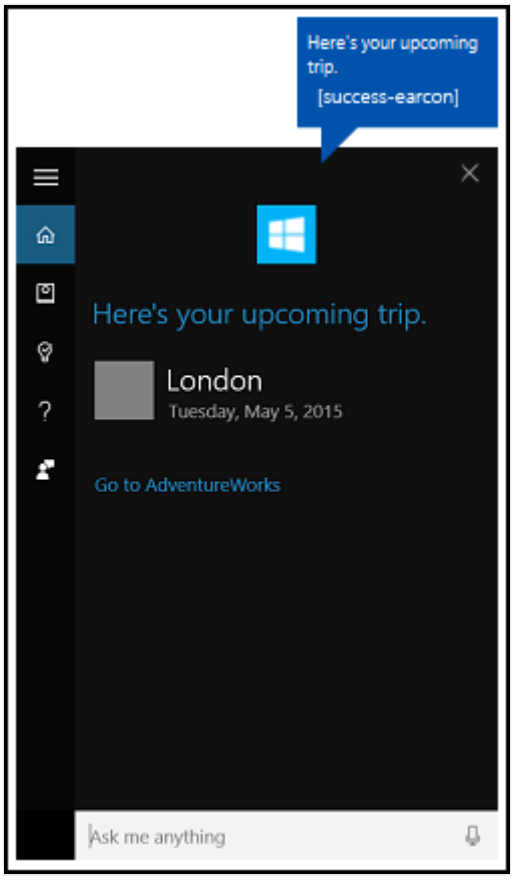
You can also let users launch your app in the foreground by clicking either a card or the text link to your app.

Completion screen

A completion screen provides the user with information about the completed voice command task.

Tasks that take less than 500 milliseconds for your app to respond, and require no additional information from the user, are completed without further interaction with **Cortana**. Cortana simply displays the completion screen.

Here, we use the **Adventure Works** app to show the completion screen for a voice command request to display upcoming trips to London.



The voice command is defined in AdventureWorksCommands.xml:

XML

```
<Command Name="whenIsTripToDestination">
  <Example> When is my trip to Las Vegas?</Example>
  <ListenFor RequireAppName="BeforeOrAfterPhrase"> when is [my] trip to
{destination}</ListenFor>
  <ListenFor RequireAppName="ExplicitlySpecified"> when is [my]
{builtin:AppName} trip to {destination} </ListenFor>
  <Feedback> Looking for trip to {destination}</Feedback>
  <VoiceCommandService Target="AdventureWorksVoiceCommandService"/>
</Command>
```

AdventureWorksVoiceCommandService.cs contains the completion message method:

C#

```
/// <summary>
/// Show details for a single trip, if the trip can be found.
/// This demonstrates a simple response flow in Cortana.
/// </summary>
/// <param name="destination">The destination, expected to be in the phrase
list.</param>
private async Task SendCompletionMessageForDestination(string destination)
{
    // If this operation is expected to take longer than 0.5 seconds, the
task must
```

```
    // supply a progress response to Cortana before starting the operation,
and
    // updates must be provided at least every 5 seconds.
    string loadingTripToDestination = string.Format(
                cortanaResourceMap.GetValue("LoadingTripToDestination",
cortanaContext).ValueAsString,
                destination);
    await ShowProgressScreen(loadingTripToDestination);
    Model.TripStore store = new Model.TripStore();
    await store.LoadTrips();

    // Query for the specified trip.
    // The destination should be in the phrase list. However, there might be
    // multiple trips to the destination. We pick the first.
    IEnumerable<Model.Trip> trips = store.Trips.Where(p => p.Destination ==
destination);

    var userMessage = new VoiceCommandUserMessage();
    var destinationsContentTiles = new List<VoiceCommandContentTile>();
    if (trips.Count() == 0)
    {
        string foundNoTripToDestination = string.Format(
                cortanaResourceMap.GetValue("FoundNoTripToDestination",
cortanaContext).ValueAsString,
                destination);
        userMessage.DisplayMessage = foundNoTripToDestination;
        userMessage.SpokenMessage = foundNoTripToDestination;
    }
    else
    {
        // Set plural or singular title.
        string message = "";
        if (trips.Count() > 1)
        {
            message = cortanaResourceMap.GetValue("PluralUpcomingTrips",
cortanaContext).ValueAsString;
        }
        else
        {
            message = cortanaResourceMap.GetValue("SingularUpcomingTrip",
cortanaContext).ValueAsString;
        }
        userMessage.DisplayMessage = message;
        userMessage.SpokenMessage = message;

        // Define a tile for each destination.
        foreach (Model.Trip trip in trips)
        {
            int i = 1;

            var destinationTile = new VoiceCommandContentTile();

            destinationTile.ContentTileType =
VoiceCommandContentTileType.TitleWith68x68IconAndText;
            destinationTile.Image = await
```

```
StorageFile.GetFileFromApplicationUriAsync(new Uri("ms-
appx:///AdventureWorks.VoiceCommands/Images/GreyTile.png"));

            destinationTile.AppLaunchArgument = trip.Destination;
            destinationTile.Title = trip.Destination;
            if (trip.StartDate != null)
            {
                destinationTile.TextLine1 =
trip.StartDate.Value.ToString(dateFormatInfo.LongDatePattern);
            }
            else
            {
                destinationTile.TextLine1 = trip.Destination + " " + i;
            }

            destinationsContentTiles.Add(destinationTile);
            i++;
        }
    }

    var response = VoiceCommandResponse.CreateResponse(userMessage,
destinationsContentTiles);

    if (trips.Count() > 0)
    {
        response.AppLaunchArgument = destination;
    }

    await voiceServiceConnection.ReportSuccessAsync(response);
}
```

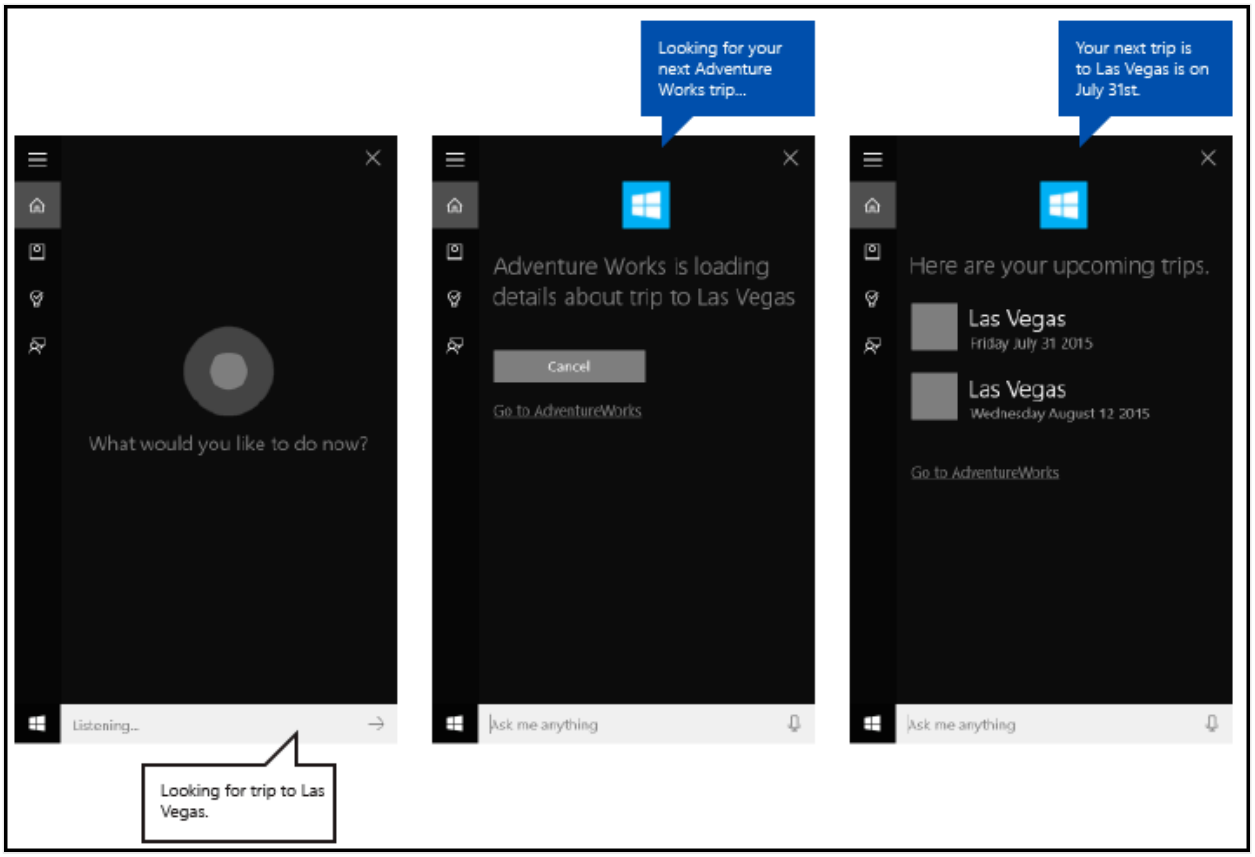
Hand-off screen

Once a voice command is recognized, **Cortana** must call ReportSuccessAsync and present feedback within approximately 500If the app service cannot complete the action specified by the voice command within 500ms, **Cortana** presents a hand-off screen that is shown until your app calls ReportSuccessAsync, or for up to 5 seconds.

If the app service doesn't call ReportSuccessAsync, or any other VoiceCommandServiceConnection method, the user receives an error message and the app service call is cancelled.

Here's an example of a hand-off screen for the **Adventure Works** app. In this example, a user has queried **Cortana** for upcoming trips. The hand-off screen includes a message customized with the app service name, an icon, and a **Feedback** string.

[!NOTE] You can declare a **Feedback** string in the VCD file. This string does not affect the UI text displayed on the Cortana canvas, it only affects the text spoken by **Cortana**.

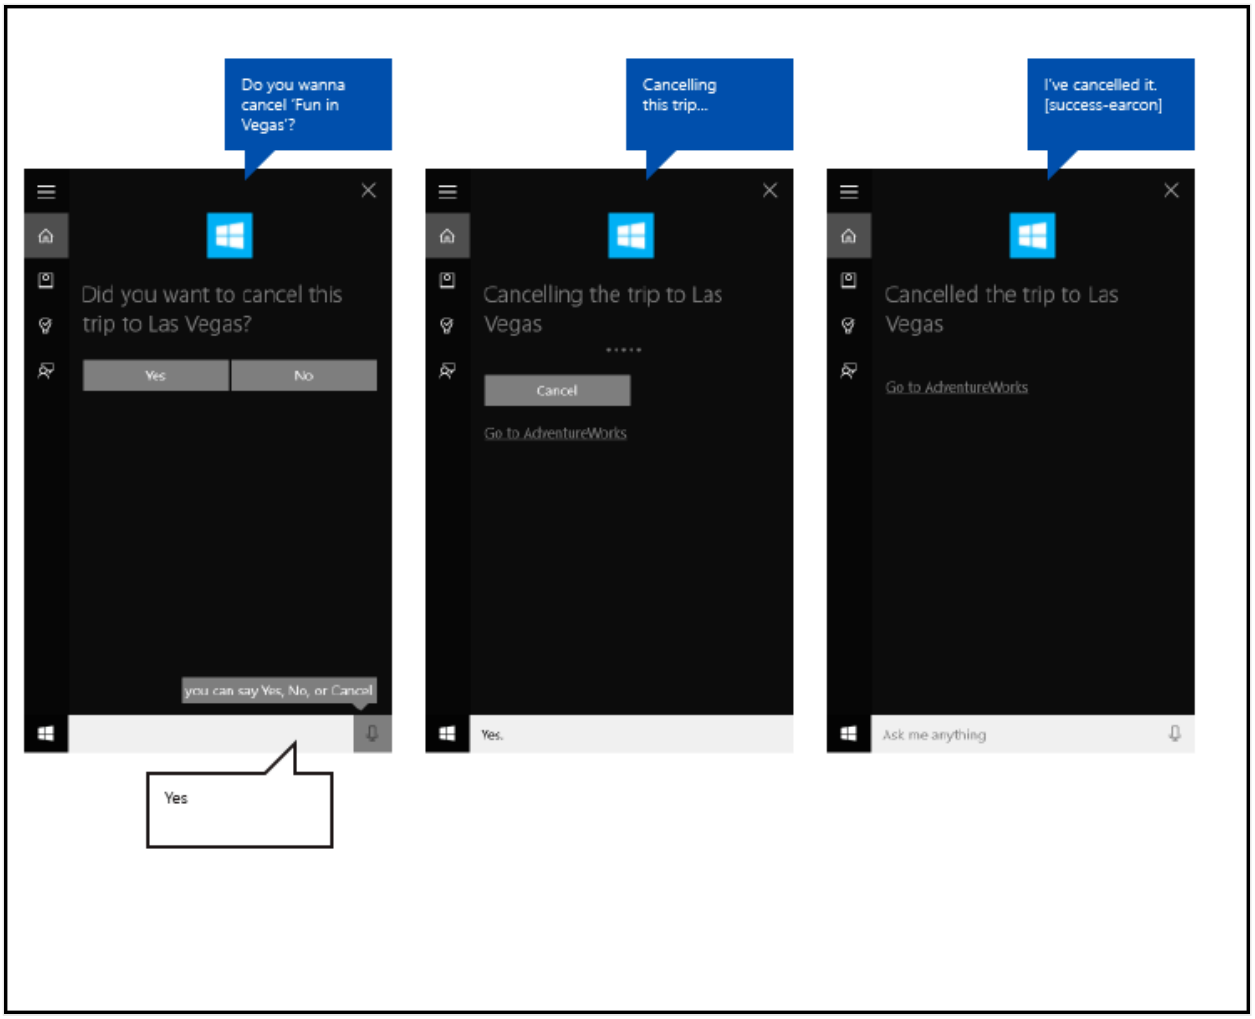


Progress screen

If the app service takes more than 500ms to call ReportSuccessAsync, **Cortana** provides the user with a progress screen. The app icon is displayed, and you must provide both GUI and TTS progress strings to indicate that the task is being actively handled.

Cortana shows a progress screen for a maximum of 5 seconds. After 5 seconds, **Cortana** presents the user with an error message and the app service is closed. If the app service needs more than 5 seconds to complete the action, it can continue to update **Cortana** with progress screens.

Here's an example of a progress screen for the **Adventure Works** app. In this example, a user has canceled a trip to Las Vegas. The progress screen includes a message customized for the action, an icon, and a content tile with information about the trip being canceled.



AdventureWorksVoiceCommandService.cs contains the following progress message method, which calls **ReportProgressAsync** to show the progress screen in **Cortana**.

CSharp

```
/// <summary>
/// Show a progress screen. These should be posted at least every 5 seconds
for a
/// long-running operation.
/// </summary>
/// <param name="message">The message to display, relating to the task being
performed.</param>
/// <returns></returns>
private async Task ShowProgressScreen(string message)
{
    var userProgressMessage = new VoiceCommandUserMessage();
    userProgressMessage.DisplayMessage = userProgressMessage.SpokenMessage =
message;

    VoiceCommandResponse response =
VoiceCommandResponse.CreateResponse(userProgressMessage);
    await voiceServiceConnection.ReportProgressAsync(response);
}
```

Confirmation screen

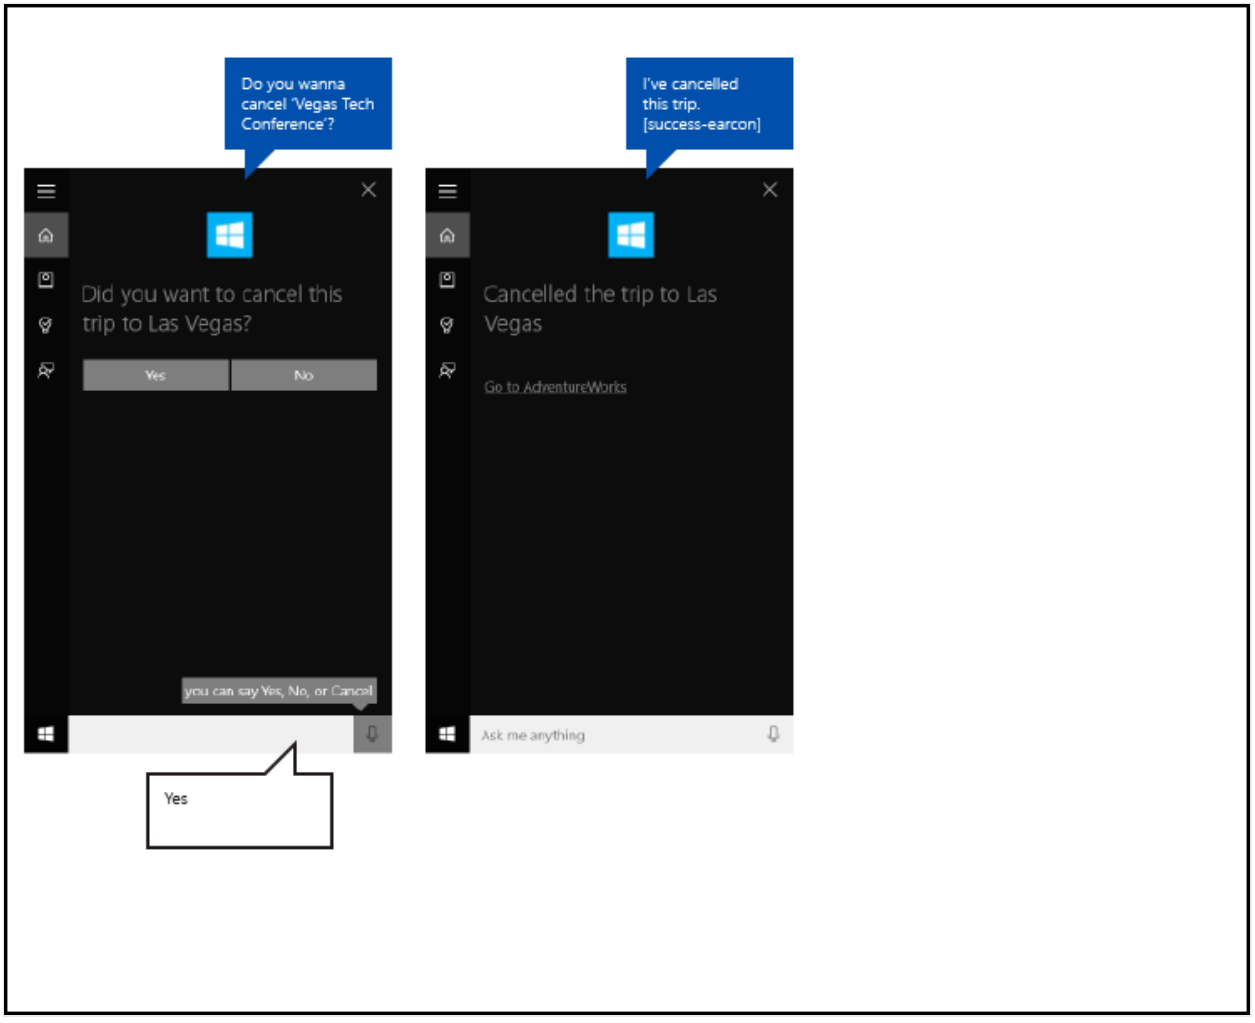
When an action specified by a voice command is irreversible, has a significant impact, or the recognition confidence is not high, an app service can request confirmation.

Here's an example of a confirmation screen for the **Adventure Works** app. In this example, a user has instructed the app service to cancel a trip to Las Vegas through **Cortana**. The app service has provided **Cortana** with a confirmation screen that prompts the user for a yes or no answer before canceling the trip.

If the user says something other than "Yes" or "No", **Cortana** cannot determine the answer to the question. In this case, **Cortana** prompts the user with a similar question provided by the app service.

On the second prompt, if the user still doesn't say "Yes" or "No", **Cortana** prompts the user a third time with the same question prefixed with an apology. If the user still doesn't say "Yes" or "No", **Cortana** stops listening for voice input and asks the user to tap one of the buttons instead.

The confirmation screen includes a message customized for the action, an icon, and a content tile with information about the trip being canceled.



AdventureWorksVoiceCommandService.cs contains the following trip cancellation method, which calls **RequestConfirmationAsync** to show a confirmation screen in **Cortana**.

CSharp

```
/// <summary>
/// Handle the Trip Cancellation task. This task demonstrates how to prompt
a user
/// for confirmation of an operation, show users a progress screen while
performing
/// a long-running task, and show a completion screen.
/// </summary>
/// <param name="destination">The name of a destination.</param>
/// <returns></returns>
private async Task SendCompletionMessageForCancellation(string destination)
{
    // Begin loading data to search for the target store.
    // Consider inserting a progress screen here, in order to prevent
Cortana from timing out.
    string progressScreenString = string.Format(
        cortanaResourceMap.GetValue("ProgressLookingForTripToDest",
cortanaContext).ValueAsString,
        destination);
    await ShowProgressScreen(progressScreenString);

    Model.TripStore store = new Model.TripStore();
    await store.LoadTrips();

    IEnumerable<Model.Trip> trips = store.Trips.Where(p => p.Destination ==
destination);
    Model.Trip trip = null;
    if (trips.Count() > 1)
    {
        // If there is more than one trip, provide a disambiguation screen.
        // However, if a significant number of items are returned, you might
want to
        // just display a link to your app and provide a deeper search
experience.
        string disambiguationDestinationString = string.Format(
            cortanaResourceMap.GetValue("DisambiguationWhichTripToDest",
cortanaContext).ValueAsString,
            destination);
        string disambiguationRepeatString =
cortanaResourceMap.GetValue("DisambiguationRepeat",
cortanaContext).ValueAsString;
        trip = await DisambiguateTrips(trips,
disambiguationDestinationString, disambiguationRepeatString);
    }
    else
    {
        trip = trips.FirstOrDefault();
    }
```

```
    var userPrompt = new VoiceCommandUserMessage();

    VoiceCommandResponse response;
    if (trip == null)
    {
        var userMessage = new VoiceCommandUserMessage();
        string noSuchTripToDestination = string.Format(
            cortanaResourceMap.GetValue("NoSuchTripToDestination",
cortanaContext).ValueAsString,
            destination);
        userMessage.DisplayMessage = userMessage.SpokenMessage =
noSuchTripToDestination;

        response = VoiceCommandResponse.CreateResponse(userMessage);
        await voiceServiceConnection.ReportSuccessAsync(response);
    }
    else
    {
        // Prompt the user for confirmation that this is the correct trip to
cancel.
        string cancelTripToDestination = string.Format(
            cortanaResourceMap.GetValue("CancelTripToDestination",
cortanaContext).ValueAsString,
            destination);
        userPrompt.DisplayMessage = userPrompt.SpokenMessage =
cancelTripToDestination;
        var userReprompt = new VoiceCommandUserMessage();
        string confirmCancelTripToDestination = string.Format(
            cortanaResourceMap.GetValue("ConfirmCancelTripToDestination",
cortanaContext).ValueAsString,
            destination);
        userReprompt.DisplayMessage = userReprompt.SpokenMessage =
confirmCancelTripToDestination;

        response = VoiceCommandResponse.CreateResponseForPrompt(userPrompt,
userReprompt);

        var voiceCommandConfirmation = await
voiceServiceConnection.RequestConfirmationAsync(response);

        // If RequestConfirmationAsync returns null, Cortana has likely been
dismissed.
        if (voiceCommandConfirmation != null)
        {
            if (voiceCommandConfirmation.Confirmed == true)
            {
                string cancellingTripToDestination = string.Format(
               cortanaResourceMap.GetValue("CancellingTripToDestination",
cortanaContext).ValueAsString,
               destination);
                await ShowProgressScreen(cancellingTripToDestination);

                // Perform the operation to remove the trip from app data.
                // As the background task runs within the app package of the
```

```
installed app,
                // we can access local files belonging to the app without
issue.
                await store.DeleteTrip(trip);

                // Provide a completion message to the user.
                var userMessage = new VoiceCommandUserMessage();
                string cancelledTripToDestination = string.Format(

cortanaResourceMap.GetValue("CancelledTripToDestination",
cortanaContext).ValueAsString,
                    destination);
                userMessage.DisplayMessage = userMessage.SpokenMessage =
cancelledTripToDestination;
                response = VoiceCommandResponse.CreateResponse(userMessage);
                await voiceServiceConnection.ReportSuccessAsync(response);
            }
            else
            {
                // Confirm no action for the user.
                var userMessage = new VoiceCommandUserMessage();
                string keepingTripToDestination = string.Format(
                    cortanaResourceMap.GetValue("KeepingTripToDestination",
cortanaContext).ValueAsString,
                    destination);
                userMessage.DisplayMessage = userMessage.SpokenMessage =
keepingTripToDestination;

                response = VoiceCommandResponse.CreateResponse(userMessage);
                await voiceServiceConnection.ReportSuccessAsync(response);
            }
        }
    }
}
```

Disambiguation screen

When an action specified by a voice command has more than one possible outcome, an app service can request more info from the user.

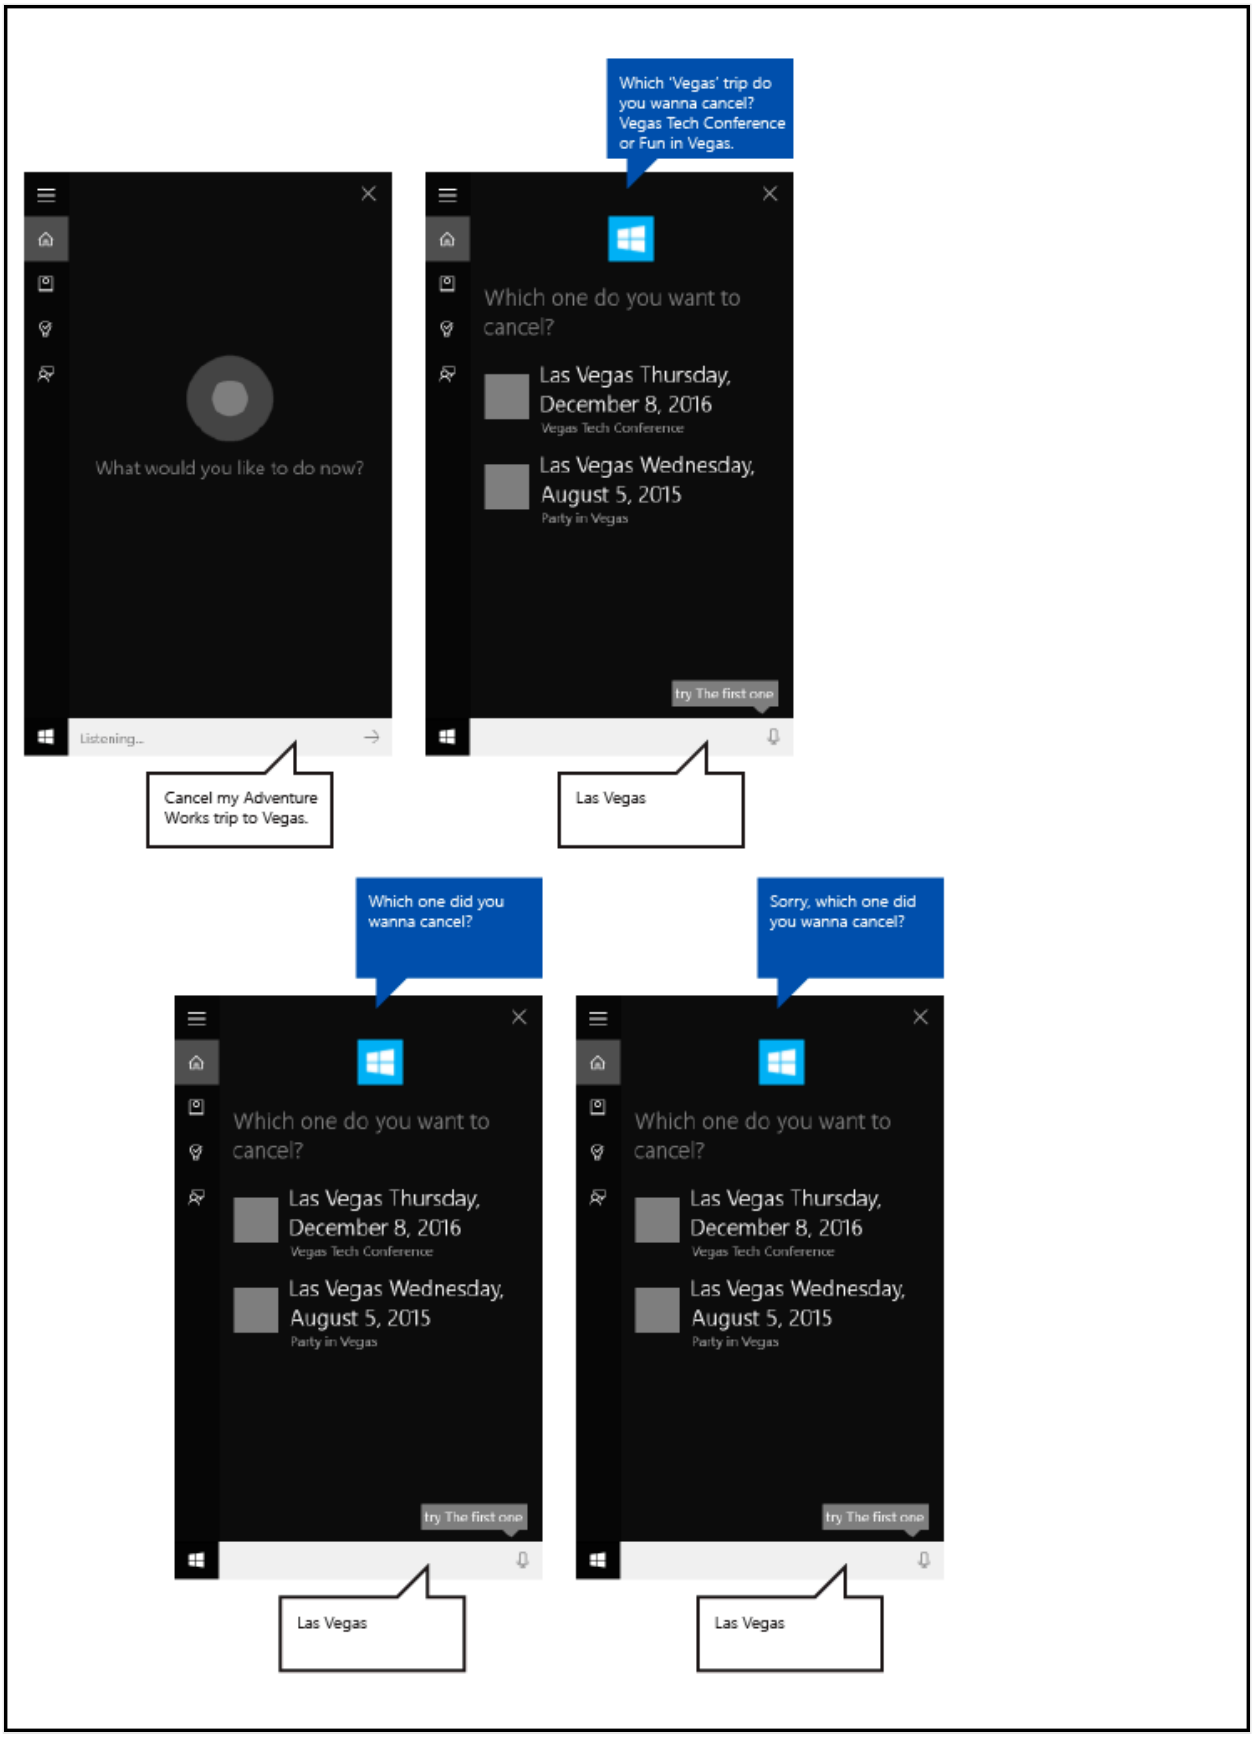
Here's an example of a disambiguation screen for the **Adventure Works** app. In this example, a user has instructed the app service to cancel a trip to Las Vegas through **Cortana**. However, the user has two trips to Las Vegas on different dates and the app service cannot complete the action without the user selecting the intended trip.

The app service provides **Cortana** with a disambiguation screen that prompts the user to make a selection from a list of matching trips, before it cancels any.

In this case, **Cortana** prompts the user with a similar question provided by the app service.

On the second prompt, if the user still doesn't say something that can be used to identify the selection, **Cortana** prompts the user a third time with the same question prefixed with an apology. If the user still doesn't say something that can be used to identify the selection, **Cortana** stops listening for voice input and asks the user to tap one of the buttons instead.

The disambiguation screen includes a message customized for the action, an icon, and a content tile with information about the trip being canceled.



AdventureWorksVoiceCommandService.cs contains the following trip cancellation method, which calls **RequestDisambiguationAsync** to show the disambiguation screen in **Cortana**.

```
C#
```

```
/// <summary>
/// Provide the user with a way to identify which trip to cancel.
/// </summary>
/// <param name="trips">The set of trips</param>
/// <param name="disambiguationMessage">The initial disambiguation
message</param>
/// <param name="secondDisambiguationMessage">Repeat prompt retry
message</param>
private async Task<Model.Trip> DisambiguateTrips(IEnumerable<Model.Trip>
trips, string disambiguationMessage, string secondDisambiguationMessage)
{
    // Create the first prompt message.
    var userPrompt = new VoiceCommandUserMessage();
    userPrompt.DisplayMessage =
        userPrompt.SpokenMessage = disambiguationMessage;

    // Create a re-prompt message if the user responds with an out-of-
grammar response.
    var userReprompt = new VoiceCommandUserMessage();
    userReprompt.DisplayMessage =
        userReprompt.SpokenMessage = secondDisambiguationMessage;

    // Create card for each item.
    var destinationContentTiles = new List<VoiceCommandContentTile>();
    int i = 1;
    foreach (Model.Trip trip in trips)
    {
        var destinationTile = new VoiceCommandContentTile();

        destinationTile.ContentTileType =
VoiceCommandContentTileType.TitleWith68x68IconAndText;
        destinationTile.Image = await
StorageFile.GetFileFromApplicationUriAsync(new Uri("ms-
appx:///AdventureWorks.VoiceCommands/Images/GreyTile.png"));

        // The AppContext can be any arbitrary object.
        destinationTile.AppContext = trip;
        string dateFormat = "";
        if (trip.StartDate != null)
        {
            dateFormat =
trip.StartDate.Value.ToString(dateFormatInfo.LongDatePattern);
        }
        else
        {
            // The app allows a trip to have no date.
            // However, the choices must be unique so they can be
distinguished.
            // Here, we add a number to identify them.
            dateFormat = string.Format("{0}", i);
        }

        destinationTile.Title = trip.Destination + " " + dateFormat;
        destinationTile.TextLine1 = trip.Description;
```

```
        destinationContentTiles.Add(destinationTile);
        i++;
    }

    // Cortana handles re-prompting if no valid response.
    var response = VoiceCommandResponse.CreateResponseForPrompt(userPrompt,
userReprompt, destinationContentTiles);

    // If cortana is dismissed in this operation, null is returned.
    var voiceCommandDisambiguationResult = await
        voiceServiceConnection.RequestDisambiguationAsync(response);
    if (voiceCommandDisambiguationResult != null)
    {
        return
(Model.Trip)voiceCommandDisambiguationResult.SelectedItem.AppContext;
    }

    return null;
}
```

Error screen

When an action specified by a voice command cannot be completed, an app service can provide an error screen.

Here's an example of an error screen for the **Adventure Works** app. In this example, a user has instructed the app service to cancel a trip to Las Vegas through **Cortana**. However, the user does not have any trips scheduled to Las Vegas.

The app service provides **Cortana** with an error screen that includes a message customized for the action, an icon, and the specific error message.

Call ReportFailureAsync to show the error screen in **Cortana**.

C#

```
var userMessage = new VoiceCommandUserMessage();
    userMessage.DisplayMessage = userMessage.SpokenMessage =
      "Sorry, you don't have any trips to Las Vegas";

    var response = VoiceCommandResponse.CreateResponse(userMessage);

    response.AppLaunchArgument = "showUpcomingTrips";
    await voiceServiceConnection.ReportFailureAsync(response);
```

Deep link from a background app in Cortana to a foreground app

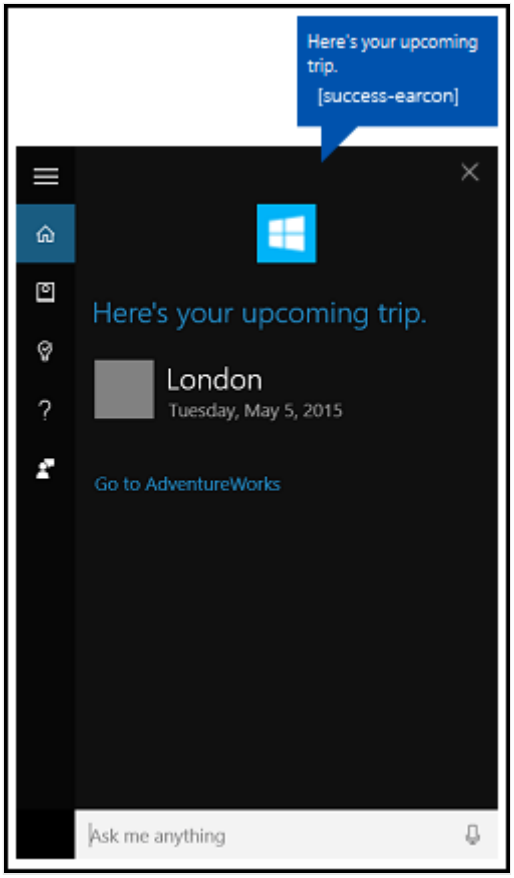
Article • 06/24/2021

> ⚠ **Warning**
>
> This feature is no longer supported as of the Windows 10 May 2020 Update (version 2004, codename "20H1").

Provide deep links from a background app in **Cortana** that launch the app to the foreground in a specific state or context.

> ⓘ **Note**
>
> Both **Cortana** and the background app service are terminated when the foreground app is launched.

A deep link is displayed by default on the **Cortana** completion screen as shown here ("Go to AdventureWorks"), but you can display deep links on various other screens.



> **Note**
>
> **Important APIs**

> - Windows.ApplicationModel.VoiceCommands
> - VCD elements and attributes v1.2

Overview

Users can access your app through **Cortana** by:

- Activating it as a foreground app (see Activate a foreground app with voice commands through Cortana).
- Exposing specific functionality as a background app service (see Activate a background app in Cortana using voice commands).
- Deep linking to specific pages, content, and state or context.

We discuss deep linking here.

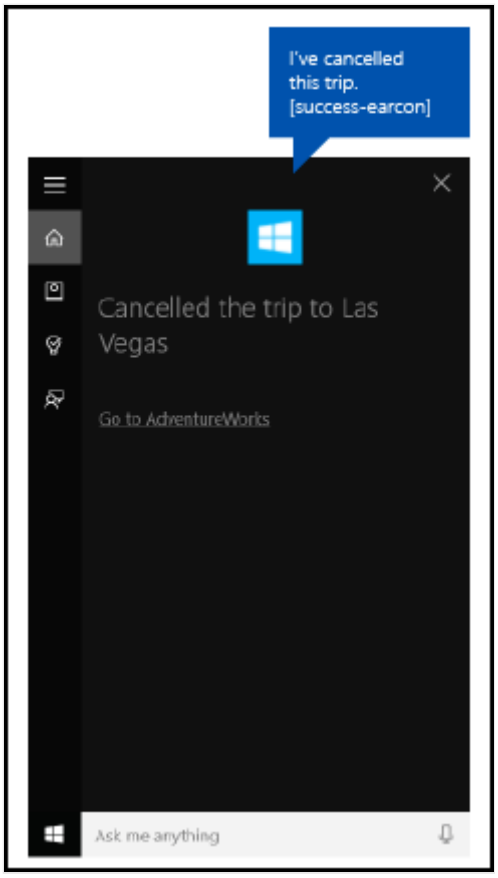
Deep linking is useful when Cortana and your app service act as a gateway to your full-featured app (instead of requiring the user to launch the app through the Start menu), or for providing access to richer detail and functionality within your app that is not possible through Cortana. Deep linking is another way to increase usability and promote your app.

There are three ways to provide deep links:

- A "Go to <app>" link on various **Cortana** screens.
- A link embedded in a content tile on various **Cortana** screens.
- Programmatically launching the foreground app from the background app service.

"Go to <app>" deep link

Cortana displays a "Go to <app>" deep link below the content card on most screens.



You can provide a launch argument for this link that opens your app in similar context as the app service. If you don't provide a launch argument, the app is launched to the main screen.

In this example from AdventureWorksVoiceCommandService.cs of the **AdventureWorks** sample, we pass the specified destination (`destination`) string to the SendCompletionMessageForDestination method, which retrieves all matching trips and provides a deep link to the app.

First, we create a **VoiceCommandUserMessage** (`userMessage`) that is spoken by **Cortana** and shown on the **Cortana** canvas. A **VoiceCommandContentTile** list object is then created for displaying the collection of result cards on the canvas.

These two objects are then passed to the CreateResponse method of the **VoiceCommandResponse** object (`response`). We then set the **AppLaunchArgument** property value of the response object to the value of `destination` passed to this function. When a user taps a content tile on the Cortana canvas, the parameter values are passed to the app through the response object.

Finally, we call the **ReportSuccessAsync** method of the **VoiceCommandServiceConnection**.

```
C#
```

```
/// <summary>
/// Show details for a single trip, if the trip can be found.
/// This demonstrates a simple response flow in Cortana.
/// </summary>
/// <param name="destination">The destination specified in the voice
command.</param>
private async Task SendCompletionMessageForDestination(string destination)
{
...
    IEnumerable<Model.Trip> trips = store.Trips.Where(p => p.Destination ==
destination);

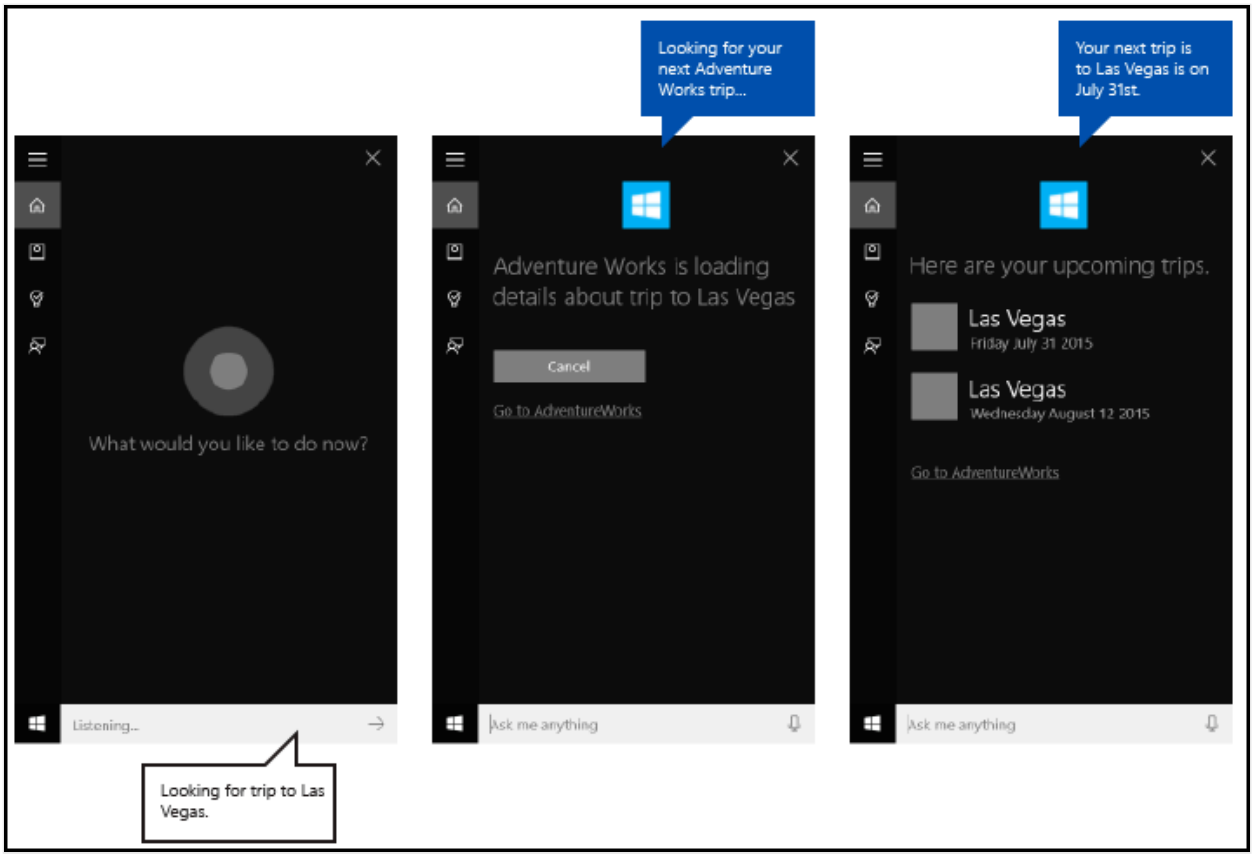
    var userMessage = new VoiceCommandUserMessage();
    var destinationsContentTiles = new List<VoiceCommandContentTile>();
...
    var response = VoiceCommandResponse.CreateResponse(userMessage,
destinationsContentTiles);

    if (trips.Count() > 0)
    {
        response.AppLaunchArgument = destination;
    }

    await voiceServiceConnection.ReportSuccessAsync(response);
}
```

Content tile deep link

You can add deep links to content cards on various **Cortana** screens.



AdventureWorks "Upcoming trip" with handoff screen

Like the "Go to <app>" links, you can provide a launch argument to open your app with similar context as the app service. If you don't provide a launch argument, the content tile does not link to your app.

In this example from AdventureWorksVoiceCommandService.cs of the **AdventureWorks** sample, we pass the specified destination to the SendCompletionMessageForDestination method, which retrieves all matching trips and provides content cards with deep links to the app.

First, we create a **VoiceCommandUserMessage** (`userMessage`) that is spoken by **Cortana** and shown on the **Cortana** canvas. A **VoiceCommandContentTile** list object is then created for displaying the collection of result cards on the canvas.

These two objects are then passed to the CreateResponse method of the **VoiceCommandResponse** object (`response`). We then set the **AppLaunchArgument** property value to the value of the destination in the voice command.

Finally, we call the **ReportSuccessAsync** method of the **VoiceCommandServiceConnection**. Here, we add two content tiles with different **AppLaunchArgument** parameter values to a **VoiceCommandContentTile** list used in the **ReportSuccessAsync** call of the **VoiceCommandServiceConnection** object.

```
C#
```

```
/// <summary>
/// Show details for a single trip, if the trip can be found.
/// This demonstrates a simple response flow in Cortana.
/// </summary>
/// <param name="destination">The destination specified in the voice
command.</param>
private async Task SendCompletionMessageForDestination(string destination)
{
    // If this operation is expected to take longer than 0.5 seconds, the
task must
    // supply a progress response to Cortana before starting the operation,
and
    // updates must be provided at least every 5 seconds.
    string loadingTripToDestination = string.Format(
                cortanaResourceMap.GetValue("LoadingTripToDestination",
cortanaContext).ValueAsString,
                destination);
    await ShowProgressScreen(loadingTripToDestination);
    Model.TripStore store = new Model.TripStore();
    await store.LoadTrips();

    // Query for the specified trip.
    // The destination should be in the phrase list. However, there might be
    // multiple trips to the destination. We pick the first.
    IEnumerable<Model.Trip> trips = store.Trips.Where(p => p.Destination ==
destination);

    var userMessage = new VoiceCommandUserMessage();

    if (trips.Count() == 0)
    {
        string foundNoTripToDestination = string.Format(
                cortanaResourceMap.GetValue("FoundNoTripToDestination",
cortanaContext).ValueAsString,
                destination);
        userMessage.DisplayMessage = foundNoTripToDestination;
        userMessage.SpokenMessage = foundNoTripToDestination;
    }
    else
    {
        // Set plural or singular title.
        string message = "";
        if (trips.Count() > 1)
        {
            message = cortanaResourceMap.GetValue("PluralUpcomingTrips",
cortanaContext).ValueAsString;
        }
        else
        {
            message = cortanaResourceMap.GetValue("SingularUpcomingTrip",
cortanaContext).ValueAsString;
        }
        userMessage.DisplayMessage = message;
        userMessage.SpokenMessage = message;
```

```
        // Define a tile for each destination.
        foreach (Model.Trip trip in trips)
        {
            int i = 1;

            var destinationTile = new VoiceCommandContentTile();

            destinationTile.ContentTileType =
VoiceCommandContentTileType.TitleWith68x68IconAndText;
            destinationTile.Image = await
StorageFile.GetFileFromApplicationUriAsync(new Uri("ms-
appx:///AdventureWorks.VoiceCommands/Images/GreyTile.png"));

            destinationTile.AppLaunchArgument = trip.Destination;
            destinationTile.Title = trip.Destination;
            if (trip.StartDate != null)
            {
                destinationTile.TextLine1 =
trip.StartDate.Value.ToString(dateFormatInfo.LongDatePattern);
            }
            else
            {
                destinationTile.TextLine1 = trip.Destination + " " + i;
            }

            destinationsContentTiles.Add(destinationTile);
            i++;
        }
    }

    var response = VoiceCommandResponse.CreateResponse(userMessage,
destinationsContentTiles);

    if (trips.Count() > 0)
    {
        response.AppLaunchArgument = destination;
    }

    await voiceServiceConnection.ReportSuccessAsync(response);
}
```

Programmatic deep link

You can also programmatically launch your app with a launch argument to open your app with similar context as the app service. If you don't provide a launch argument, the app is launched to the main screen.

Here, we add an **AppLaunchArgument** parameter with a value of "Las Vegas" to a **VoiceCommandResponse** object used in the **RequestAppLaunchAsync** call of the

VoiceCommandServiceConnection object.

```CSharp
var userMessage = new VoiceCommandUserMessage();
userMessage.DisplayMessage = "Here are your trips.";
userMessage.SpokenMessage =
  "You have one trip to Vegas coming up.";

response = VoiceCommandResponse.CreateResponse(userMessage);
response.AppLaunchArgument = "Las Vegas";
await  VoiceCommandServiceConnection.RequestAppLaunchAsync(response);
```

App manifest

To enable deep linking to your app, you must declare the `windows.personalAssistantLaunch` extension in the Package.appxmanifest file of your app project.

Here, we declare the `windows.personalAssistantLaunch` extension for the **Adventure Works** app.

```XML
<Extensions>
  <uap:Extension Category="windows.appService"

EntryPoint="AdventureWorks.VoiceCommands.AdventureWorksVoiceCommandService">
    <uap:AppService Name="AdventureWorksVoiceCommandService"/>
  </uap:Extension>
  <uap:Extension Category="windows.personalAssistantLaunch"/>
</Extensions>
```

Protocol contract

Your app is launched to the foreground through Uniform Resource Identifier (URI) activation using a **Protocol** contract. Your app must override your app's **OnActivated** event and check for an **ActivationKind** of **Protocol**. For more info, see Handle URI activation.

Here, we decode the URI provided by the **ProtocolActivatedEventArgs** to access the launch argument. For this example, the **Uri** is set to "windows.personalassistantlaunch:?LaunchContext=Las Vegas".

```
```

CSharp

```
if (args.Kind == ActivationKind.Protocol)
  {
    var commandArgs = args as ProtocolActivatedEventArgs;
    Windows.Foundation.WwwFormUrlDecoder decoder =
      new Windows.Foundation.WwwFormUrlDecoder(commandArgs.Uri.Query);
    var destination = decoder.GetFirstValueByName("LaunchContext");

    navigationCommand = new ViewModel.TripVoiceCommand(
      "protocolLaunch",
      "text",
      "destination",
      destination);

    navigationToPageType = typeof(View.TripDetails);

    rootFrame.Navigate(navigationToPageType, navigationCommand);

    // Ensure the current window is active.
    Window.Current.Activate();
  }
```

Support natural language voice commands in Cortana

Article • 06/24/2021

> ⚠ **Warning**
>
> This feature is no longer supported as of the Windows 10 May 2020 Update (version 2004, codename "20H1").

Extend **Cortana** with more flexible and natural voice commands that let a user say your app's name anywhere in the command.

> ⓘ **Note**
>
> **Important APIs**
>
> - Windows.ApplicationModel.VoiceCommands
> - VCD elements and attributes v1.2

Using voice commands to extend Cortana with functionality from your app requires the user to specify both the app and the command or function to execute. This is typically accomplished by announcing the app name at the beginning or the end of the voice command. For example, "Adventure Works, add a new trip to Las Vegas."

However, specifying the application name in this way can sound awkward, stilted, or not even make sense. In many cases, being able to say the app name elsewhere in the command is more comfortable and natural, and helps make the interaction much more intuitive and engaging for the user. Our previous example, "Adventure Works, add a new trip to Las Vegas." could be rephrased as "Add a new Adventure Works trip to Las Vegas." or "Using Adventure Works, add a new trip to Las Vegas."

You can set up your voice commands to support the app name as a:

- Prefix - before the command phrase
- Infix - within the command phrase
- Suffix - after the command phrase

> 💡 **Tip**

Prerequisites

This topic builds on Activate a background app in Cortana using voice commands. We continue here to demonstrate features with a trip planning and management app named **Adventure Works**.

If you're new to developing Universal Windows Platform (UWP) apps, have a look through these topics to get familiar with the technologies discussed here.

- Create your first app

User experience guidelines

See Cortana design guidelines for info about how to integrate your app with **Cortana** and Speech interactions for helpful tips on designing a useful and engaging speech-enabled app.

Specify an AppName element in the VCD

The **AppName** element is used to specify a user-friendly name for an app in a voice command.

```
XML
<AppName>Adventure Works</AppName>
```

Specify where the app name can be spoken in the voice command

The **ListenFor** element has a **RequireAppName** attribute that specifies where the app name can appear in the voice command. This attribute supports four values.

1. **BeforePhrase**

   Default.

   Indicates that users must say your app name before the command phrase.

   Here, Cortana listens for "Adventure Works when is my trip to Las Vegas".

   ```
   XML
   ```

```
<ListenFor RequireAppName="BeforePhrase"> show [my] trip to
{destination} </ListenFor>
```

2. **AfterPhrase**

   Indicates that users must say your app name after the command phrase.

   A localized phrase list of prepositional conjunctions is provided by the system. This includes phrases such as, "using", "with "and "on".

   Here, Cortana listens for commands like "Show my next trip to Las Vegas on Adventure Works" and "Show my next trip to Las Vegas using Adventure Works".

   XML

   ```
   <ListenFor RequireAppName="AfterPhrase">show [my] next trip to
   {destination} </ListenFor>
   ```

3. **BeforeOrAfterPhrase**

   Indicates that users must say your app name either before or after the command phrase.

   For the suffix version, a localized phrase list of prepositional conjunctions is provided by the system. This includes phrases such as, "using", "with "and "on".

   Here, Cortana listens for commands like "Adventure Works, show my next trip to Las Vegas" or "Show my next trip to Last Vegas on Adventure works".

   XML

   ```
   <ListenFor RequireAppName="BeforeOrAfterPhrase">show [my] next trip to
   {destination}</ListenFor>
   ```

4. **ExplicitlySpecified**

   Indicates that users must say your app name exactly where you specify in the command phrase. The user is not required to say the app name either before or after the phrase.

   You must explicitly reference your app name using the **{builtin:AppName}** tag.

   Here, Cortana listens for commands like "Adventure Works, show my next trip to Las Vegas" or "Show my next Adventure Works trip to Las Vegas".

XML

```
<ListenFor RequireAppName="ExplicitlySpecified">show [my] next
{builtin:AppName} trip to {destination} </ListenFor>
```

Special cases

When you declare a **ListenFor** element where **RequireAppName** is either "AfterPhrase" or "ExplicitlySpecified", you must ensure certain requirements are met:

1. **{builtin:AppName}** must appear once and only once when **RequireAppName** is "ExplicitlySpecified".

   With this value, the system cannot infer where the app name can appear in the voice command. You must explicitly specify the location.

2. You cannot have a voice command begin with a **PhraseTopic** element, which is typically used for large vocabulary speech recognition. At least one word must precede it.

   This helps to minimize the chance that **Cortana** launches your app if a command contains your app name, or part of it, anywhere in the utterance.

   Here is an invalid declaration that could lead to **Cortana** launching the **Adventure Works** app if the user says something like "Show me reviews for Kinect Adventure works".

   XML

   ```
   <ListenFor RequireAppName="ExplicitlySpecified">{searchPhrase}
   {builtin:AppName}</ListenFor>
   ```

3. There must be at least two words in the **ListenFor** string besides your app name and references to **PhraseTopic** elements.

   Similar to case 2, you need to ensure your commands contain sufficient phonetic content to minimize the chances your app is launched unintentionally.

   This helps you set up your application for best possible success so your application does not get incorrectly launched when user says for example "Find Kinect Adventure works".

   Here are invalid declarations that could lead to **Cortana** launching the **Adventure Works** app if the user says something like "Hey adventure works" or "Find Kinect

adventure works".

XML

```
<ListenFor RequireAppName="ExplicitlySpecified">Hey {builtin:AppName}
</ListenFor>
<ListenFor RequireAppName="ExplicitlySpecified">Find {searchPhrase}
{builtin:AppName}</ListenFor>
```

Remarks

Supporting more variation in how a voice command can be uttered by a user in **Cortana** also increases the general usability of your app.

Avoid having "Hey [app name]" as your **AppName**. Users are much more likely to say "Hey Cortana" to invoke Cortana through voice activation, and having "Hey [app name]" in the utterance does not sound natural. For example, "Hey Cortana, show my next trip to Las Vegas on Hey Adventure Works".

Consider adding infix/suffix variations to your existing voice commands. As we've shown here, it doesn't require a lot of effort to add an additional attribute to your existing **ListenFor** elements and support suffix variants. It feels a lot more natural to say "Hey Cortana, show my next trip to Las Vegas on Adventure works" than "Hey Cortana, Adventure Works, show my next trip to Las Vegas".

Consider using your app name as a prefix in cases where the voice command conflicts with existing **Cortana** functionality (calling, messaging, and so on). For example, "Adventure Works, message [travel agent] about Las Vegas trip".

Complete example

Here is a VCD file that demonstrates various ways to provide more natural language voice commands.

> **Note**
>
> It is valid to have multiple **ListenFor** elements, each with a different **RequireAppName** attribute value.

XML

```
<?xml version="1.0" encoding="utf-8"?>
<VoiceCommands xmlns="https://schemas.microsoft.com/voicecommands/1.1">
  <CommandSet xml:lang="en-us" Name="commandSet_en-us">
    <AppName>Adventure Works</AppName>
    <Example> When is my trip to Las Vegas? </Example>
    <Command Name="whenIsTripToDestination">
      <Example> When is my trip to Las Vegas?</Example>
      <ListenFor RequireAppName="BeforePhrase">
        when is my] trip to {destination} </ListenFor>

      <!-- This ListenFor command will set up Cortana to accept commands
like
           "Show my next trip to Las Vegas on Adventure Works"; "Show my
next
           trip to Las Vegas using Adventure Works" -->
      <ListenFor RequireAppName="AfterPhrase">
        show [my] next trip to {destination} </ListenFor>

      <!-- This ListenFor command will set up Cortana to accept commands
when
           the user specifies your app name either before or after the
command.
           "Adventure Works, show my next trip to Las Vegas";
           "Show my next trip to Last Vegas on Adventure works" -->
      <ListenFor RequireAppName="BeforeOrAfterPhrase">
        show [my] next trip to {destination} </ListenFor>

      <!-- This ListenFor command will set up Cortana to accept commands
           when the user specifies your app name inline.
           "Show my next Adventure Works trip to Las Vegas" -->
      <ListenFor RequireAppName="ExplicitlySpecified">
        show [my] next {builtin:AppName} trip to {destination} </ListenFor>

      <Feedback> Looking for trip to {destination} </Feedback>
      <Navigate />
    </Command>
    <PhraseList Label="destination">
      <Item> Las Vegas </Item>
      <Item> Dallas </Item>
      <Item> New York </Item>
    </PhraseList>
  </CommandSet>
  <!-- Other CommandSets for other languages -->
</VoiceCommands>
```

Multiple inputs

Article • 06/24/2021

Just as people use a combination of voice and gesture when communicating with each other, multiple types and modes of input can also be useful when interacting with an app.

To accommodate as many users and devices as possible, we recommend that you design your apps to work with as many input types as possible (gesture, speech, touch, touchpad, mouse, and keyboard). Doing so will maximize flexibility, usability, and accessibility.

To begin, consider the various scenarios in which your app handles input. Try to be consistent throughout your app, and remember that the platform controls provide built-in support for multiple input types.

- Can users interact with the application through multiple input devices?
- Are all input methods supported at all times? With certain controls? At specific times or circumstances?
- Does one input method take priority?

Single (or exclusive)-mode interactions

With single-mode interactions, multiple input types are supported, but only one can be used per action. For example, speech recognition for commands, and gestures for navigation; or, text entry using touch or gestures, depending on proximity.

Multimodal interactions

With multimodal interactions, multiple input methods in sequence are used to complete a single action.

Speech + gesture
The user points to a product, and then says “Add to cart.”

Speech + touch
The user selects a photo using press and hold, and then says “Send photo.”

Simulate user input through input injection

Article • 06/24/2021

Simulate and automate user input from devices such as keyboard, mouse, touch, pen, and gamepad in your Windows applications.

> **Important APIs**: Windows.UI.Input.Preview.Injection

Overview

Input injection enables your Windows application to simulate input from a variety of input devices and direct that input anywhere, including outside your app's client area (even to apps running with Administrator privileges, such as the Registry Editor).

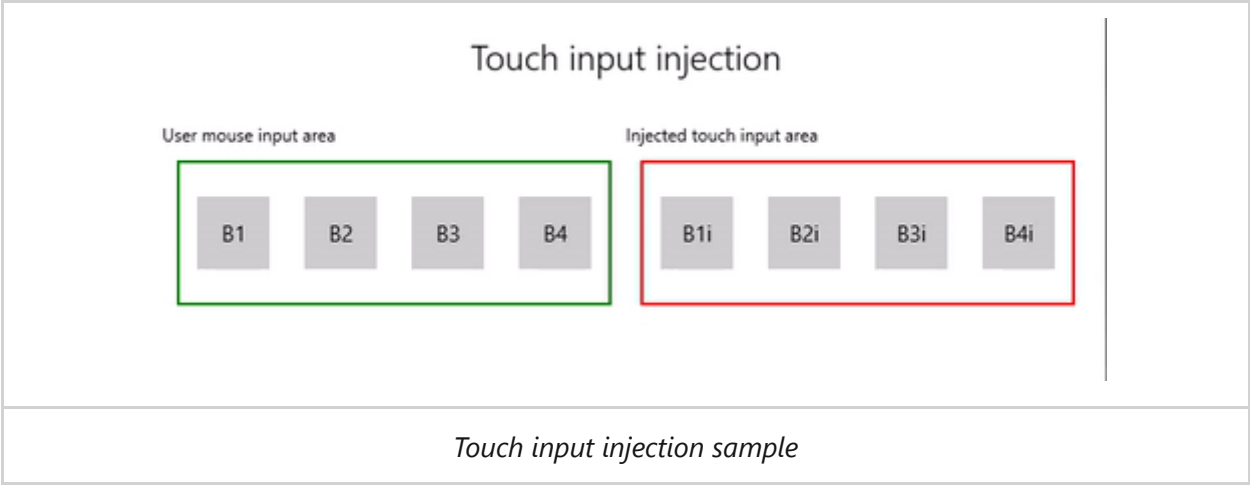
Input injection is useful for Windows apps and tools that need to provide functionality that includes accessibility, testing (ad-hoc, automated), and remote access and support features.

Setup

To use the input injection APIs in your Windows app you'll need to add the following to the app manifest:

1. Right click the **Package.appxmanifest** file and select **View code**.
2. Insert the following into the `Package` node:
    - `xmlns:rescap="http://schemas.microsoft.com/appx/manifest/foundation/windows10/restrictedcapabilities"`
    - `IgnorableNamespaces="rescap"`
3. Insert the following into the `Capabilities` node:
    - `<rescap:Capability Name="inputInjectionBrokered" />`

Duplicate user input



Touch input injection sample

In this example, we demonstrate how to use the input injection APIs (Windows.UI.Input.Preview.Injection) to listen for mouse input events in one region of an app, and simulate corresponding touch input events in another region.

Download this sample from Input injection sample (mouse to touch)

1. First, we set up the UI (MainPage.xaml).

   We have two Grid areas (one for mouse input and one for injected touch input), each with four buttons.

   > **Note**
   >
   > The Grid background must be assigned a value (`Transparent`, in this case), otherwise pointer events are not detected.

   When any mouse clicks are detected in the input area, a corresponding touch event is injected into the input injection area. Button clicks from inject input are reported in the title area.

   XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="Auto"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>
    <StackPanel Grid.Row="0"
                Margin="10">
        <TextBlock Style="{ThemeResource TitleTextBlockStyle}"
                   Name="titleText"
                   Text="Touch input injection"
                   HorizontalTextAlignment="Center" />
        <TextBlock Style="{ThemeResource BodyTextBlockStyle}"
```

```
                    Name="statusText"
                    HorizontalTextAlignment="Center" />
    </StackPanel>
    <Grid HorizontalAlignment="Center"
                     Grid.Row="1">
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto"/>
            <RowDefinition Height="*"/>
        </Grid.RowDefinitions>
        <Grid.ColumnDefinitions>
            <ColumnDefinition/>
            <ColumnDefinition/>
        </Grid.ColumnDefinitions>
        <TextBlock Grid.Column="0"
                   Grid.Row="0"
                   Style="{ThemeResource CaptionTextBlockStyle}"
                   Text="User mouse input area"/>
        <!-- Background must be set to something, otherwise pointer
events are not detected. -->
        <Grid Name="ContainerInput"
              Grid.Column="0"
              Grid.Row="1"
              HorizontalAlignment="Stretch"
              Background="Transparent"
              BorderBrush="Green"
              BorderThickness="2"
              MinHeight="100" MinWidth="300"
              Margin="10">
            <Grid.ColumnDefinitions>
                <ColumnDefinition/>
                <ColumnDefinition/>
                <ColumnDefinition/>
                <ColumnDefinition/>
            </Grid.ColumnDefinitions>
            <Button Name="B1"
                    Grid.Column="0"
                    HorizontalAlignment="Center"
                    Width="50" Height="50"
                    Content="B1" />
            <Button Name="B2"
                    Grid.Column="1"
                    HorizontalAlignment="Center"
                    Width="50" Height="50"
                    Content="B2" />
            <Button Name="B3"
                    Grid.Column="2"
                    HorizontalAlignment="Center"
                    Width="50" Height="50"
                    Content="B3" />
            <Button Name="B4"
                    Grid.Column="3"
                    HorizontalAlignment="Center"
                    Width="50" Height="50"
                    Content="B4" />
        </Grid>
```

```
        <TextBlock Grid.Column="1"
                   Grid.Row="0"
                   Style="{ThemeResource CaptionTextBlockStyle}"
                   Text="Injected touch input area"/>
        <Grid Name="ContainerInject"
              Grid.Column="1"
              Grid.Row="1"
              HorizontalAlignment="Stretch"
              BorderBrush="Red"
              BorderThickness="2"
              MinHeight="100" MinWidth="300"
              Margin="10">
            <Grid.ColumnDefinitions>
                <ColumnDefinition/>
                <ColumnDefinition/>
                <ColumnDefinition/>
                <ColumnDefinition/>
            </Grid.ColumnDefinitions>
            <Button Name="B1i" Click="Button_Click_Injected"
                    Content="B1i"
                    Grid.Column="0"
                    HorizontalAlignment="Center"
                    Width="50" Height="50" />
            <Button Name="B2i" Click="Button_Click_Injected"
                    Content="B2i"
                    Grid.Column="1"
                    HorizontalAlignment="Center"
                    Width="50" Height="50" />
            <Button Name="B3i" Click="Button_Click_Injected"
                    Content="B3i"
                    Grid.Column="2"
                    HorizontalAlignment="Center"
                    Width="50" Height="50" />
            <Button Name="B4i" Click="Button_Click_Injected"
                    Content="B4i"
                    Grid.Column="3"
                    HorizontalAlignment="Center"
                    Width="50" Height="50" />
        </Grid>
    </Grid>
</Grid>
```

2. Next, we initialize our app.

   In this snippet, we declare our global objects and declare listeners for pointer events (AddHandler) within the mouse input area that might be marked as handled in the button click events.

   The InputInjector object represents the virtual input device for sending the input data.

   In the `ContainerInput_PointerPressed` handler we call the touch injection function.

In the `ContainerInput_PointerReleased` handler, we call UninitializeTouchInjection to shut down the InputInjector object.

C#

```
public sealed partial class MainPage : Page
{
    /// <summary>
    /// The virtual input device.
    /// </summary>
    InputInjector _inputInjector;

    /// <summary>
    /// Initialize the app, set the window size,
    /// and add pointer input handlers for the container.
    /// </summary>
    public MainPage()
    {
        this.InitializeComponent();

        ApplicationView.PreferredLaunchViewSize =
            new Size(600, 200);
        ApplicationView.PreferredLaunchWindowingMode =
            ApplicationViewWindowingMode.PreferredLaunchViewSize;

        // Button handles PointerPressed/PointerReleased in
        // the Tapped routed event, but we need the container Grid
        // to handle them also. Add a handler for both
        // PointerPressedEvent and PointerReleasedEvent on the input
Grid
        // and set handledEventsToo to true.
        ContainerInput.AddHandler(PointerPressedEvent,
            new PointerEventHandler(ContainerInput_PointerPressed),
true);
        ContainerInput.AddHandler(PointerReleasedEvent,
            new PointerEventHandler(ContainerInput_PointerReleased),
true);
    }

    /// <summary>
    /// PointerReleased handler for all pointer conclusion events.
    /// PointerPressed and PointerReleased events do not always occur
    /// in pairs, so your app should listen for and handle any event
that
    /// might conclude a pointer down (such as PointerExited,
PointerCanceled,
    /// and PointerCaptureLost).
    /// </summary>
    /// <param name="sender">Source of the click event</param>
    /// <param name="e">Event args for the button click routed
event</param>
    private void ContainerInput_PointerReleased(
        object sender, PointerRoutedEventArgs e)
    {
```

```
        // Prevent most handlers along the event route from handling
event again.
        e.Handled = true;

        // Shut down the virtual input device.
        _inputInjector.UninitializeTouchInjection();
    }

    /// <summary>
    /// PointerPressed handler.
    /// PointerPressed and PointerReleased events do not always occur
    /// in pairs. Your app should listen for and handle any event that
    /// might conclude a pointer down (such as PointerExited,
    /// PointerCanceled, and PointerCaptureLost).
    /// </summary>
    /// <param name="sender">Source of the click event</param>
    /// <param name="e">Event args for the button click routed
event</param>
    private void ContainerInput_PointerPressed(
        object sender, PointerRoutedEventArgs e)
    {
        // Prevent most handlers along the event route from
        // handling the same event again.
        e.Handled = true;

        InjectTouchForMouse(e.GetCurrentPoint(ContainerInput));

    }
    ...
}
```

3. Here's the touch input injection function.

   First, we call TryCreate to instantiate the InputInjector object.

   Then, we call InitializeTouchInjection with an InjectedInputVisualizationMode of `Default`.

   After calculating the point of injection, we call InjectedInputTouchInfo to initialize the list of touch points to inject (for this example, we create one touch point corresponding to the mouse input pointer).

   Finally, we call InjectTouchInput twice, the first for a pointer down and the second for a pointer up.

```
C#
```

```
/// <summary>
/// Inject touch input on injection target corresponding
/// to mouse click on input target.
/// </summary>
```

```
/// <param name="pointerPoint">The mouse click pointer.</param>
private void InjectTouchForMouse(PointerPoint pointerPoint)
{
    // Create the touch injection object.
    _inputInjector = InputInjector.TryCreate();

    if (_inputInjector != null)
    {
        _inputInjector.InitializeTouchInjection(
            InjectedInputVisualizationMode.Default);

        // Create a unique pointer ID for the injected touch pointer.
        // Multiple input pointers would require more robust handling.
        uint pointerId = pointerPoint.PointerId + 1;

        // Get the bounding rectangle of the app window.
        Rect appBounds =

Windows.UI.ViewManagement.ApplicationView.GetForCurrentView().VisibleBo
unds;

        // Get the top left screen coordinates of the app window rect.
        Point appBoundsTopLeft = new Point(appBounds.Left,
appBounds.Top);

        // Get a reference to the input injection area.
        GeneralTransform injectArea =
            ContainerInject.TransformToVisual(Window.Current.Content);

        // Get the top left screen coordinates of the input injection
area.
        Point injectAreaTopLeft = injectArea.TransformPoint(new
Point(0, 0));

        // Get the screen coordinates (relative to the input area)
        // of the input pointer.
        int pointerPointX = (int)pointerPoint.Position.X;
        int pointerPointY = (int)pointerPoint.Position.Y;

        // Create the point for input injection and calculate its
screen location.
        Point injectionPoint =
            new Point(
                appBoundsTopLeft.X + injectAreaTopLeft.X +
pointerPointX,
                appBoundsTopLeft.Y + injectAreaTopLeft.Y +
pointerPointY);

        // Create a touch data point for pointer down.
        // Each element in the touch data list represents a single
touch contact.
        // For this example, we're mirroring a single mouse pointer.
        List<InjectedInputTouchInfo> touchData =
            new List<InjectedInputTouchInfo>
            {
```

```
                new InjectedInputTouchInfo
                {
                    Contact = new InjectedInputRectangle
                    {
                        Left = 30, Top = 30, Bottom = 30, Right = 30
                    },
                    PointerInfo = new InjectedInputPointerInfo
                    {
                        PointerId = pointerId,
                        PointerOptions =
                        InjectedInputPointerOptions.PointerDown |
                        InjectedInputPointerOptions.InContact |
                        InjectedInputPointerOptions.New,
                        TimeOffsetInMilliseconds = 0,
                        PixelLocation = new InjectedInputPoint
                        {
                            PositionX = (int)injectionPoint.X ,
                            PositionY = (int)injectionPoint.Y
                        }
                },
                Pressure = 1.0,
                TouchParameters =
                    InjectedInputTouchParameters.Pressure |
                    InjectedInputTouchParameters.Contact
            }
        };

        // Inject the touch input.
        _inputInjector.InjectTouchInput(touchData);

        // Create a touch data point for pointer up.
        touchData = new List<InjectedInputTouchInfo>
        {
            new InjectedInputTouchInfo
            {
                PointerInfo = new InjectedInputPointerInfo
                {
                    PointerId = pointerId,
                    PointerOptions =
InjectedInputPointerOptions.PointerUp
                }
            }
        };

        // Inject the touch input.
        _inputInjector.InjectTouchInput(touchData);
    }
}
```

4. Finally, we handle any Button Click routed events in the input injection area and update the UI with the name of the button clicked.

Identify input devices

Article • 06/24/2021

Identify the input devices connected to a Windows app device and identify their capabilities and attributes.

> **Important APIs**: Windows.Devices.Input, Windows.UI.Input, Windows.UI.Xaml.Input

Retrieve mouse properties

The Windows.Devices.Input namespace contains the MouseCapabilities class used to retrieve the properties exposed by one or more connected mice. Just create a new **MouseCapabilities** object and get the properties you're interested in.

Note The values returned by the properties discussed here are based on all detected mice: Boolean properties return non-zero if at least one mouse supports a specific capability, and numeric properties return the maximum value exposed by any one mouse.

The following code uses a series of TextBlock elements to display the individual mouse properties and values.

CSharp

```
private void GetMouseProperties()
{
    MouseCapabilities mouseCapabilities = new
Windows.Devices.Input.MouseCapabilities();
    MousePresent.Text = mouseCapabilities.MousePresent != 0 ? "Yes" : "No";
    VertWheel.Text = mouseCapabilities.VerticalWheelPresent != 0 ? "Yes" :
"No";
    HorzWheel.Text = mouseCapabilities.HorizontalWheelPresent != 0 ? "Yes" :
"No";
    SwappedButtons.Text = mouseCapabilities.SwapButtons != 0 ? "Yes" : "No";
    NumButtons.Text = mouseCapabilities.NumberOfButtons.ToString();
}
```

Retrieve keyboard properties

The Windows.Devices.Input namespace contains the KeyboardCapabilities class used to retrieve whether a keyboard is connected. Just create a new **KeyboardCapabilities** object and get the KeyboardPresent property.

The following code uses a TextBlock element to display the keyboard property and value.

CSharp

```
private void GetKeyboardProperties()
{
    KeyboardCapabilities keyboardCapabilities = new
Windows.Devices.Input.KeyboardCapabilities();
    KeyboardPresent.Text = keyboardCapabilities.KeyboardPresent != 0 ? "Yes"
: "No";
}
```

Retrieve touch properties

The Windows.Devices.Input namespace contains the TouchCapabilities class used to retrieve whether any touch digitizers are connected. Just create a new **TouchCapabilities** object and get the properties you're interested in.

Note The values returned by the properties discussed here are based on all detected touch digitizers: Boolean properties return non-zero if at least one digitizer supports a specific capability, and numeric properties return the maximum value exposed by any one digitizer.

The following code uses a series of TextBlock elements to display the touch properties and values.

CSharp

```
private void GetTouchProperties()
{
    TouchCapabilities touchCapabilities = new
Windows.Devices.Input.TouchCapabilities();
    TouchPresent.Text = touchCapabilities.TouchPresent != 0 ? "Yes" : "No";
    Contacts.Text = touchCapabilities.Contacts.ToString();
}
```

Retrieve pointer properties

The Windows.Devices.Input namespace contains the PointerDevice class used to retrieve whether any detected devices support pointer input (touch, touchpad, mouse, or pen). Just create a new **PointerDevice** object and get the properties you're interested in.

Note The values returned by the properties discussed here are based on all detected pointer devices: Boolean properties return non-zero if at least one device supports a specific capability, and numeric properties return the maximum value exposed by any one pointer device.

The following code uses a table to display the properties and values for each pointer device.

CSharp

```
private void GetPointerDevices()
{
    IReadOnlyList<PointerDevice> pointerDevices =
Windows.Devices.Input.PointerDevice.GetPointerDevices();
    int gridRow = 0;
    int gridColumn = 0;

    for (int i = 0; i < pointerDevices.Count; i++)
    {
        // Pointer device type.
        TextBlock textBlock1 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock1);
        textBlock1.Text = (i + 1).ToString() + " Pointer Device Type:";
        Grid.SetRow(textBlock1, gridRow);
        Grid.SetColumn(textBlock1, gridColumn);

        TextBlock textBlock2 = new TextBlock();
        textBlock2.Text = pointerDevices[i].PointerDeviceType.ToString();
        Grid_PointerProps.Children.Add(textBlock2);
        Grid.SetRow(textBlock2, gridRow++);
        Grid.SetColumn(textBlock2, gridColumn + 1);

        // Is external?
        TextBlock textBlock3 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock3);
        textBlock3.Text = (i + 1).ToString() + " Is External?";
        Grid.SetRow(textBlock3, gridRow);
        Grid.SetColumn(textBlock3, gridColumn);

        TextBlock textBlock4 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock4);
        textBlock4.Text = pointerDevices[i].IsIntegrated.ToString();
        Grid.SetRow(textBlock4, gridRow++);
        Grid.SetColumn(textBlock4, gridColumn + 1);

        // Maximum contacts.
```

```
        TextBlock textBlock5 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock5);
        textBlock5.Text = (i + 1).ToString() + " Max Contacts:";
        Grid.SetRow(textBlock5, gridRow);
        Grid.SetColumn(textBlock5, gridColumn);

        TextBlock textBlock6 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock6);
        textBlock6.Text = pointerDevices[i].MaxContacts.ToString();
        Grid.SetRow(textBlock6, gridRow++);
        Grid.SetColumn(textBlock6, gridColumn + 1);

        // Physical device rectangle.
        TextBlock textBlock7 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock7);
        textBlock7.Text = (i + 1).ToString() + " Physical Device Rect:";
        Grid.SetRow(textBlock7, gridRow);
        Grid.SetColumn(textBlock7, gridColumn);

        TextBlock textBlock8 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock8);
        textBlock8.Text = pointerDevices[i].PhysicalDeviceRect.X.ToString()
+ "," +
            pointerDevices[i].PhysicalDeviceRect.Y.ToString() + "," +
            pointerDevices[i].PhysicalDeviceRect.Width.ToString() + "," +
            pointerDevices[i].PhysicalDeviceRect.Height.ToString();
        Grid.SetRow(textBlock8, gridRow++);
        Grid.SetColumn(textBlock8, gridColumn + 1);

        // Screen rectangle.
        TextBlock textBlock9 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock9);
        textBlock9.Text = (i + 1).ToString() + " Screen Rect:";
        Grid.SetRow(textBlock9, gridRow);
        Grid.SetColumn(textBlock9, gridColumn);

        TextBlock textBlock10 = new TextBlock();
        Grid_PointerProps.Children.Add(textBlock10);
        textBlock10.Text = pointerDevices[i].ScreenRect.X.ToString() + "," +
            pointerDevices[i].ScreenRect.Y.ToString() + "," +
            pointerDevices[i].ScreenRect.Width.ToString() + "," +
            pointerDevices[i].ScreenRect.Height.ToString();
        Grid.SetRow(textBlock10, gridRow++);
        Grid.SetColumn(textBlock10, gridColumn + 1);

        gridColumn += 2;
        gridRow = 0;
    }
```

Drag and drop

Article • 07/12/2024

Drag and drop is an intuitive way to transfer data within an application or between applications on the Windows desktop. Drag and drop lets the user transfer data between applications or within an application using a standard gesture (press-hold-and-pan with the finger or press-and-pan with a mouse or a stylus).

> **Important APIs**: CanDrag property, AllowDrop property

The drag source, which is the application or area where the drag gesture is triggered, provides the data to be transferred by filling a data package object that can contain standard data formats, including text, RTF, HTML, bitmaps, storage items or custom data formats. The source also indicates the kind of operations it supports: copy, move or link. When the pointer is released, drop occurs. The drop target, which is the application or area underneath the pointer, processes the data package and returns the type of operation it performed.

During drag and drop, the drag UI provides a visual indication of the type of drag-and-drop operation that's taking place. This visual feedback is initially provided by the source but can be changed by the targets as the pointer moves over them.

Modern drag and drop is available on all devices that support UWP. It allows data transfer between or within any kind of application, including Classic Windows apps, although this article focuses on the XAML API for modern drag and drop. Once implemented, drag and drop works seamlessly in all directions, including app-to-app, app-to-desktop, and desktop-to app.

Here's an overview of what you need to do to enable drag and drop in your app:

1. Enable dragging on an element by setting its **CanDrag** property to true.
2. Build the data package. The system handles images and text automatically, but for other content, you'll need to handle the **DragStarting** and **DropCompleted** events and use them to construct your own data package.
3. Enable dropping by setting the **AllowDrop** property to **true** on all the elements that can receive dropped content.
4. Handle the **DragOver** event to let the system know what type of drag operations the element can receive.
5. Process the **Drop** event to receive the dropped content.

Enable dragging

To enable dragging on an element, set its **CanDrag** property to **true**. This make the element—and the elements it contains, in the case of collections like ListView—draggable.

Be specific about what's draggable. Users won't want to drag everything in your app, only certain items, such as images or text.

Here's how to set **CanDrag**.

XML

```
<Image x:Name="Image" CanDrag="True" Margin="10,292,10,0" Height="338"></Image>
```

You don't need to do any other work to allow dragging, unless you want to customize the UI (which is covered later in this article). Dropping requires a few more steps.

Construct a data package

In most cases, the system will construct a data package for you. The system automatically handles:

- Images
- Text

For other content, you'll need to handle the **DragStarting** and **DropCompleted** events and use them to construct your own DataPackage.

Enable dropping

The following markup shows how the **AllowDrop** property can be used to specify that an area of the app is a valid drop target for a dragged item (the specified area must not have a null background, it must be able to receive pointer input, and the item cannot be dropped anywhere other than the specified area).

> ⓘ **Note**
>
> Typically, a UI element has a null background by default. If you want users to be able to drop an item anywhere within your app, the app background cannot be null (set `Background="Transparent"` if the background should not be visible).

XML

```
<Grid AllowDrop="True" DragOver="Grid_DragOver" Drop="Grid_Drop"
      Background="LightBlue" Margin="10,10,10,353">
    <TextBlock>Drop anywhere in the blue area</TextBlock>
</Grid>
```

Handle the DragOver event

The DragOver event fires when a user has dragged an item over your app, but not yet dropped it. In this handler, you need to specify what kind of operations your app supports by using the AcceptedOperation property. Copy is the most common.

C#

```
private void Grid_DragOver(object sender, DragEventArgs e)
{
    e.AcceptedOperation = DataPackageOperation.Copy;
}
```

Process the Drop event

The Drop event occurs when the user releases items in a valid drop area. Process them by using the DataView property.

For simplicity in the example below, we'll assume the user dropped a single photo and access it directly. In reality, users can drop multiple items of varying formats simultaneously. Your app should handle this possibility by checking what types of files were dropped and how many there are, and process each accordingly. You should also consider notifying the user if they're trying to do something your app doesn't support.

C#

```
private async void Grid_Drop(object sender, DragEventArgs e)
{
    if (e.DataView.Contains(StandardDataFormats.StorageItems))
    {
        var items = await e.DataView.GetStorageItemsAsync();
        if (items.Count > 0)
        {
            var storageFile = items[0] as StorageFile;
            var bitmapImage = new BitmapImage();
            bitmapImage.SetSource(await storageFile.OpenAsync(FileAccessMode.Read));
            // Set the image on the main page to the dropped image
            Image.Source = bitmapImage;
        }
    }
}
```

Customize the UI

The system provides a default UI for dragging and dropping. However, you can also choose to customize various parts of the UI by setting custom captions and glyphs, or by opting not to show a UI at all. To customize the UI, use the DragEventArgs.DragUIOverride property.

C#

```
private void Grid_DragOverCustomized(object sender, DragEventArgs e)
{
    e.AcceptedOperation = DataPackageOperation.Copy;
    e.DragUIOverride.Caption = "Custom text here"; // Sets custom UI text
    // Sets a custom glyph
    e.DragUIOverride.SetContentFromBitmapImage(
        new BitmapImage(
            new Uri("ms-appx:///Assets/CustomImage.png",
UriKind.RelativeOrAbsolute)));
    e.DragUIOverride.IsCaptionVisible = true; // Sets if the caption is visible
    e.DragUIOverride.IsContentVisible = true; // Sets if the dragged content is
visible
    e.DragUIOverride.IsGlyphVisible = true; // Sets if the glyph is visibile
}
```

Open a context menu on an item you can drag with touch

When using touch, dragging a **UIElement** and opening its context menu share similar touch gestures; each begins with a press and hold. Here's how the system disambiguates between the two actions for elements in your app that support both:

- If a user presses and holds an item and begins dragging it within 500 milliseconds, the item is dragged and the context menu is not shown.
- If the user presses and holds but does not drag within 500 milliseconds, the context menu is opened.
- After the context menu is open, if the user tries to drag the item (without lifting their finger), the context menu is dismissed and the drag will start.

Designate an item in a ListView or GridView as a folder

You can specify a **ListViewItem** or **GridViewItem** as a folder. This is particularly useful for TreeView and File Explorer scenarios. To do so, explicitly set the **AllowDrop** property to **True** on that item.

The system will automatically show the appropriate animations for dropping into a folder versus a non-folder item. Your app code must continue to handle the **Drop** event on the folder item (as well as on the non-folder item) in order to update the data source and add the dropped item to the target folder.

Enable drag and drop reordering within ListViews

ListViews support drag-based reordering out of the box, using an API very similar to the **CanDrop** API described in this article. At minimum, you add the **AllowDrop** and

CanReorderItems properties.

See **ListViewBase.CanReorderItems** for more information.

Implementing custom drag and drop

The UIElement class does most of the work of implementing drag-and-drop for you. But if you want, you can implement your own version by using the APIs below.

Expand table

Functionality	WinAppSDK API Microsoft.UI.Input.DragDrop namespace	UWP API Windows.Applicationmodel.DataTransfer.DragDrop.Core namespace
DragPrimitive	DragOperation	CoreDragOperation
Create a data package	DataPackage	same
Hand off drag to the shell	DragOperation.StartAsync	CoreDragOperation.StartAsync
Receive drop from the shell	DragDropManager.TargetRequested ICoreDropOperationTarget	CoreDragDropManager.TargetRequested ICoreDropOperationTarget

Optical zoom and resizing

Article • 10/31/2023

This article describes Windows zooming and resizing elements and provides user experience guidelines for using these interaction mechanisms in your apps.

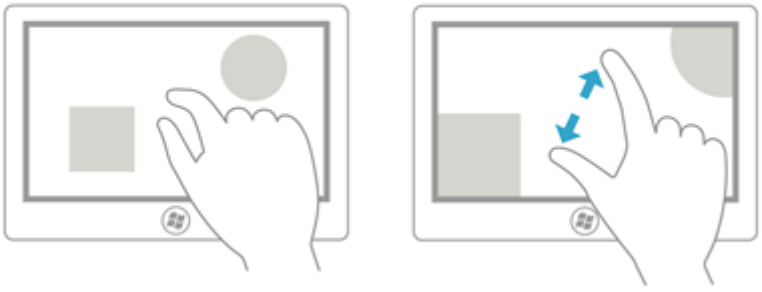
> **Important APIs**: Windows.UI.Input, Input (XAML)

Optical zoom lets users magnify their view of the content within a content area (it is performed on the content area itself), whereas resizing enables users to change the relative size of one or more objects without changing the view of the content area (it is performed on the objects within the content area).

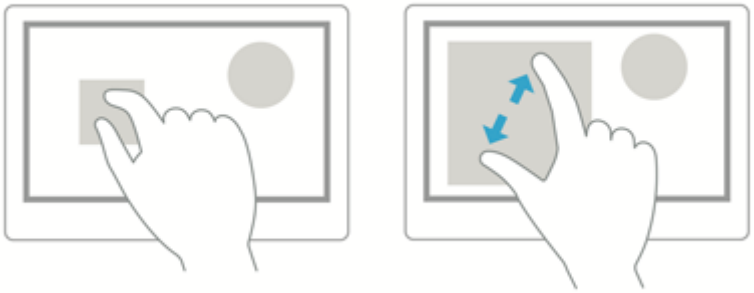
Both optical zoom and resizing interactions are performed through the pinch and stretch gestures (moving fingers farther apart zooms in and moving them closer together zooms out), or by holding the Ctrl key down while scrolling the mouse scroll wheel, or by holding the Ctrl key down (with the Shift key, if no numeric keypad is available) and pressing the plus (+) or minus (-) key.

The following diagrams demonstrate the differences between resizing and optical zooming.

Optical zoom: User selects an area, and then zooms into the entire area.



Resize: User selects an object within an area, and resizes that object.



Note Optical zoom shouldn't be confused with Semantic Zoom. Although the same gestures are used for both interactions, semantic zoom refers to the presentation and navigation of content organized within a single view (such as the folder structure of a computer, a library of documents, or a photo album).

Dos and don'ts

Use the following guidelines for apps that support either resizing or optical zooming:

- If maximum and minimum size constraints or boundaries are defined, use visual feedback to demonstrate when the user reaches or exceeds those boundaries.
- Use snap points to influence zooming and resizing behavior by providing logical points at which to stop the manipulation and ensure a specific subset of content is displayed in the viewport. Provide snap points for common zoom levels or logical views to make it easier for a user to select those levels. For example, photo apps might provide a resizing snap point at 100% or, in the case of mapping apps, snap points might be useful at city, state, and country/region views.

  Snap points enable users to be imprecise and still achieve their goals. If you're using XAML, see the snap points properties of **ScrollViewer**.

  There are two types of snap-points:
  - Proximity - After the contact is lifted, a snap point is selected if inertia stops within a distance threshold of the snap point. Proximity snap points still allow a zoom or resize to end between snap points.
  - Mandatory - The snap point selected is the one that immediately precedes or succeeds the last snap point crossed before the contact was lifted (depending on the direction and velocity of the gesture). A manipulation must end on a mandatory snap point.

- Use inertia physics. These include the following:
  - Deceleration: Occurs when the user stops pinching or stretching. This is similar to sliding to a stop on a slippery surface.
  - Bounce: A slight bounce-back effect occurs when a size constraint or boundary is passed.
- Space controls according to the Guidelines for targeting.
- Provide scaling handles for constrained resizing. Isometric, or proportional, resizing is the default if the handles are not specified.
- Don't use zooming to navigate the UI or expose additional controls within your app, use a panning region instead. For more info on panning, see Guidelines for panning.
- Don't put resizable objects within a resizable content area. Exceptions to this include:
  - Drawing applications where resizable items can appear on a resizable canvas or art board.
  - Webpages with an embedded object such as a map.

  Note In all cases, the content area is resized unless all touch points are within the resizable object.

Guidelines for panning

Article • 06/24/2021

Panning or scrolling lets users navigate within a single view, to display the content of the view that does not fit within the viewport. Examples of views include the folder structure of a computer, a library of documents, or a photo album.

> **Important APIs**: Windows.UI.Input, Windows.UI.Xaml.Input

Dos and don'ts

Panning indicators and scroll bars

- Ensure panning/scrolling is possible before loading content into your app.
- Display panning indicators and scroll bars to provide location and size cues. Hide them if you provide a custom navigation feature.

  Note Unlike standard scroll bars, panning indicators are purely informative. They are not exposed to input devices and cannot be manipulated in any way.

Single-axis panning (one-dimensional overflow)

- Use one-axis panning for content regions that extend beyond one viewport boundary (vertical or horizontal).
  - Vertical panning for a one-dimensional list of items.
  - Horizontal panning for a grid of items.
- Don’t use mandatory snap-points with single-axis panning if a user must be able to pan and stop between snap-points. Mandatory snap-points guarantee that the user will stop on a snap-point. Use proximity snap-points instead.

Freeform panning (two-dimensional overflow)

- Use two-axis panning for content regions that extend beyond both viewport boundaries (vertical and horizontal).
  - Override the default rails behavior and use freeform panning for unstructured content where the user is likely to move in multiple directions.
- Freeform panning is typically suited to navigating within images or maps.

Paged view

- Use mandatory snap-points when the content is composed of discrete elements or you want to display an entire element. This can include pages of a book or magazine, a column of items, or individual images.
  - A snap-point should be placed at each logical boundary.
  - Each element should be sized or scaled to fit the view.

Logical and key points

- Use proximity snap-points if there are key points or logical places in the content that a user will likely stop. For example, a section header.

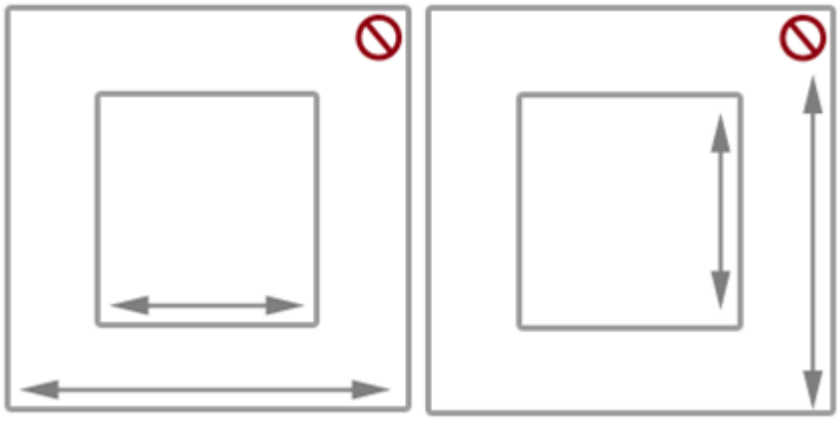
- If maximum and minimum size constraints or boundaries are defined, use visual feedback to demonstrate when the user reaches or exceeds those boundaries.

Chaining embedded or nested content

- Use single-axis panning (typically horizontal) and column layouts for text and grid-based content. In these cases, content typically wraps and flows naturally from column to column and keeps the user experience consistent and discoverable across Windows apps.

- Don't use embedded pannable regions to display text or item lists. Because the panning indicators and scroll bars are displayed only when the input contact is detected within the region, it is not an intuitive or discoverable user experience.

- Don't chain or place one pannable region within another pannable region if they both pan in the same direction, as shown here. This can result in the parent area being panned unintentionally when a boundary for the child area is reached. Consider making the panning axis perpendicular.



Additional usage guidance

Panning with touch, by using a swipe or slide gesture with one or more fingers, is like scrolling with the mouse. The panning interaction is most similar to rotating the mouse wheel or sliding the scroll box, rather than clicking the scroll bar. Unless a distinction is made in an API or required by some device-specific Windows UI, we simply refer to both interactions as panning.

> **Windows 10 Fall Creators Update - Behavior change** By default, instead of text selection, an active pen now scrolls/pans in Windows apps (like touch, touchpad, and passive pen). If your app depends on the previous behavior, you can override pen scrolling and revert to the previous behavior. For details, see the API reference topic for the ScrollViewer Class.

Depending on the input device, the user pans within a pannable region by using one of these:

- A mouse, touchpad, or active pen/stylus to click the scroll arrows, drag the scroll box, or click within the scroll bar.
- The wheel button of the mouse to emulate dragging the scroll box.
- The extended buttons (XBUTTON1 and XBUTTON2), if supported by the mouse.
- The keyboard arrow keys to emulate dragging the scroll box or the page keys to emulate clicking within the scroll bar.
- Touch, touchpad, or passive pen/stylus to slide or swipe the fingers in the desired direction.

Sliding involves moving the fingers slowly in the panning direction. This results in a one-to-one relationship, where the content pans at the same speed and distance as the fingers. Swiping, which involves rapidly sliding and lifting the fingers, results in the following physics being applied to the panning animation:

- Deceleration (inertia): Lifting the fingers causes panning to start decelerating. This is similar to sliding to a stop on a slippery surface.
- Absorption: Panning momentum during deceleration causes a slight bounce-back effect if either a snap point or a content area boundary is reached.

Types of panning

Windows supports three types of panning:

- Single axis - panning is supported in one direction only (horizontal or vertical).
- Rails - panning is supported in all directions. However, once the user crosses a distance threshold in a specific direction, then panning is restricted to that axis.
- Freeform - panning is supported in all directions.

Panning UI

The interaction experience for panning is unique to the input device while still providing similar functionality.

There are two panning display modes based on the input device detected:

- Panning indicators for touch.
- Scroll bars for other input devices, including mouse, touchpad, keyboard, and stylus.

Note Panning indicators are only visible when the touch contact is within the pannable region. Similarly, the scroll bar is only visible when the mouse cursor, pen/stylus cursor, or keyboard focus is within the scrollable region.

Panning indicators Panning indicators are similar to the scroll box in a scroll bar. They indicate the proportion of displayed content to total pannable area and the relative position of the displayed content in the pannable area.

The following diagram shows two pannable areas of different lengths and their panning indicators.

Panning behaviors Snap points Panning with the swipe gesture introduces inertia behavior into the interaction when the touch contact is lifted. With inertia, the content continues to pan until some distance threshold is reached without direct input from the user. Use snap points to modify this inertia behavior.

Snap points specify logical stops in your app content. Cognitively, snap points act as a paging mechanism for the user and minimize fatigue from excessive sliding or swiping in large pannable regions. With them, you can handle imprecise user input and ensure a specific subset of content or key information is displayed in the viewport.

There are two types of snap-points:

- Proximity - After the contact is lifted, a snap point is selected if inertia stops within a distance threshold of the snap point. Panning can still stop between proximity snap points.
- Mandatory - The snap point selected is the one that immediately precedes or succeeds the last snap point crossed before the contact was lifted (depending on the direction and velocity of the gesture). Panning must stop on a mandatory snap point.

Panning snap-points are useful for applications such as web browsers and photo albums that emulate paginated content or have logical groupings of items that can be dynamically regrouped to fit within a viewport or display.

The following diagrams show how panning to a certain point and releasing causes the content to automatically pan to a logical location.

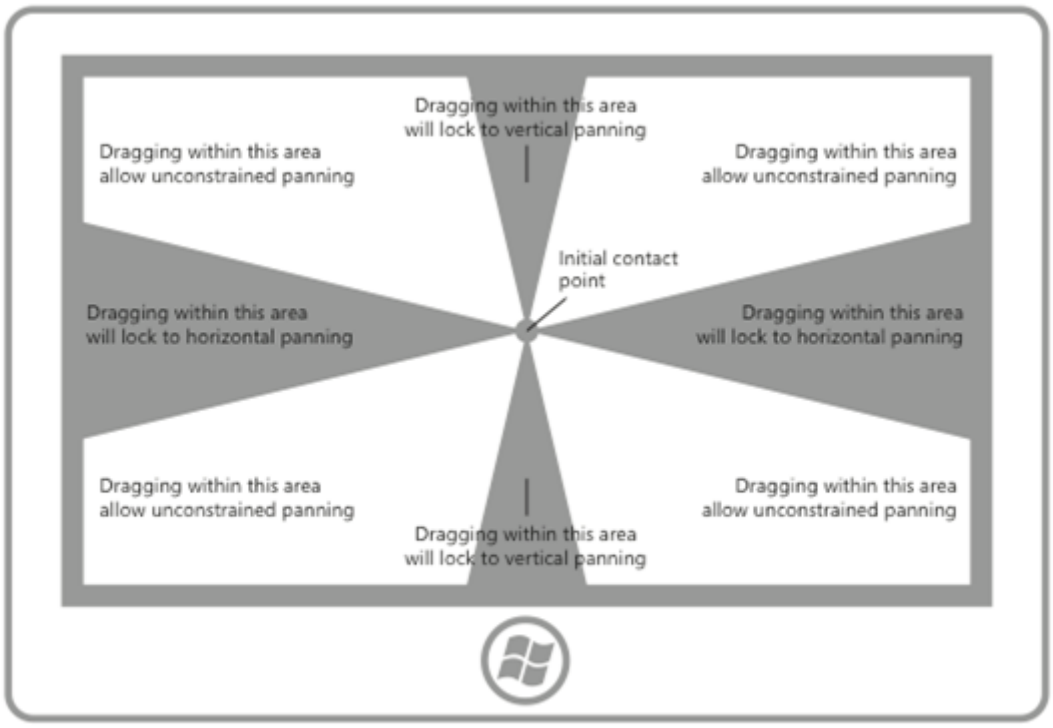
Swipe to pan.

Lift touch contact.

Pannable region stops at the snap point, not where the touch contact was lifted.

Rails Content can be wider and taller than the dimensions and resolution of a display device. For this reason, two-dimensional panning (horizontal and vertical) is often necessary. Rails improve the user experience in these cases by emphasizing panning along the axis of motion (vertical or horizontal).

The following diagram demonstrates the concept of rails.

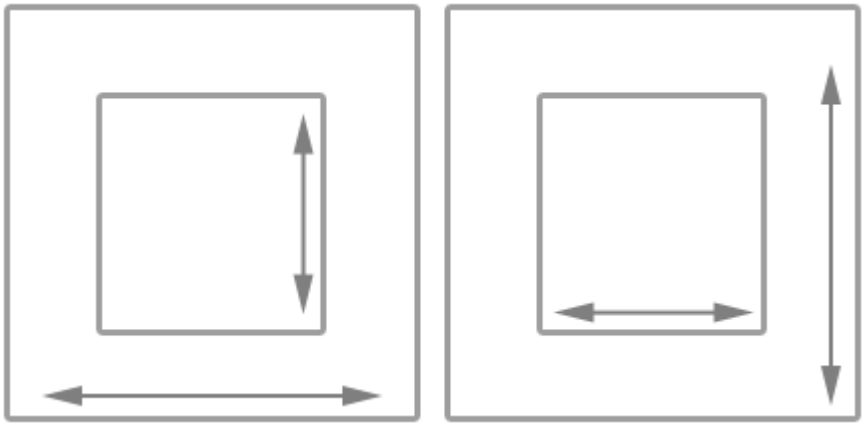


Chaining embedded or nested content

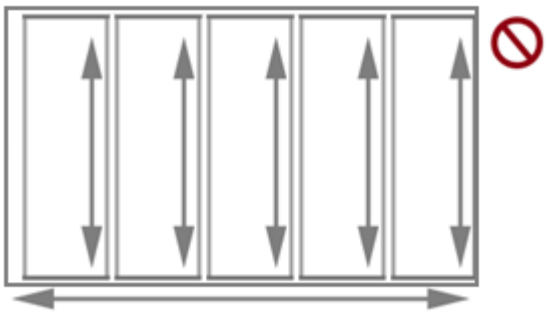
After a user hits a zoom or scroll limit on an element that has been nested within another zoomable or scrollable element, you can specify whether that parent element should continue the zooming or scrolling operation begun in its child element. This is called zoom or scroll chaining.

Chaining is used for panning within a single-axis content area that contains one or more single-axis or freeform panning regions (when the touch contact is within one of these child regions). When the panning boundary of the child region is reached in a specific direction, panning is then activated on the parent region in the same direction.

When a pannable region is nested inside another pannable region it's important to specify enough space between the container and the embedded content. In the following diagrams, one pannable region is placed inside another pannable region, each going in perpendicular directions. There is plenty of space for users to pan in each region.



Without enough space, as shown in the following diagram, the embedded pannable region can interfere with panning in the container and result in unintentional panning in one or more of the pannable regions.



This guidance is also useful for apps such as photo albums or mapping apps that support unconstrained panning within an individual image or map while also supporting single-axis panning within the album (to the previous or next images) or details area. In apps that provide a detail or options area corresponding to a freeform panning image or map, we recommend that the page layout start with the details and options area as the unconstrained panning area of the image or map might interfere with panning to the details area.

Rotation

Article • 06/24/2021

This article describes the new Windows UI for rotation and provides user experience guidelines that should be considered when using this new interaction mechanism in your Windows app.

> **Important APIs**: Windows.UI.Input, Windows.UI.Xaml.Input

Dos and don'ts

- Use rotation to help users directly rotate UI elements.

Additional usage guidance

Overview of rotation

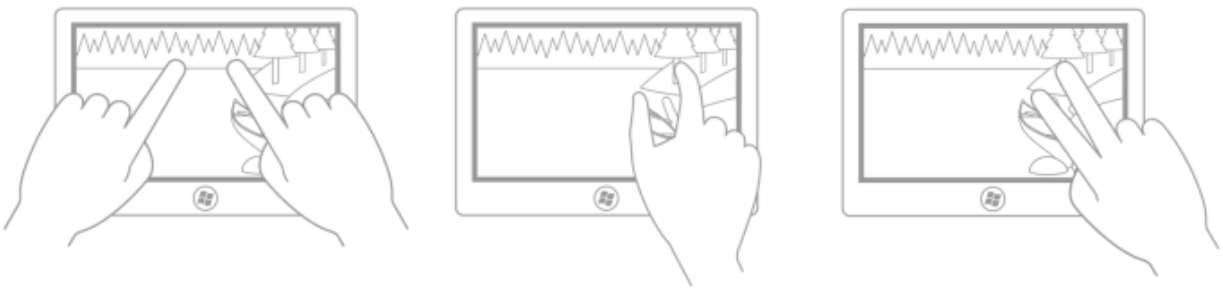
Rotation is the touch-optimized technique used by Windows apps to enable users to turn an object in a circular direction (clockwise or counter-clockwise).

Depending on the input device, the rotation interaction is performed using:

- A mouse or active pen/stylus to move the rotation gripper of a selected object.
- Touch or passive pen/stylus to turn the object in the desired direction using the rotate gesture.

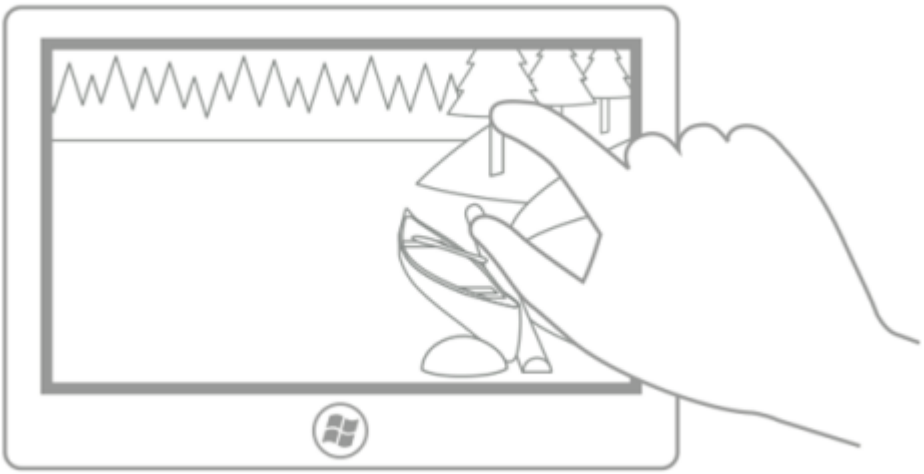
When to use rotation

Use rotation to help users directly rotate UI elements. The following diagrams show some of the supported finger positions for the rotation interaction.

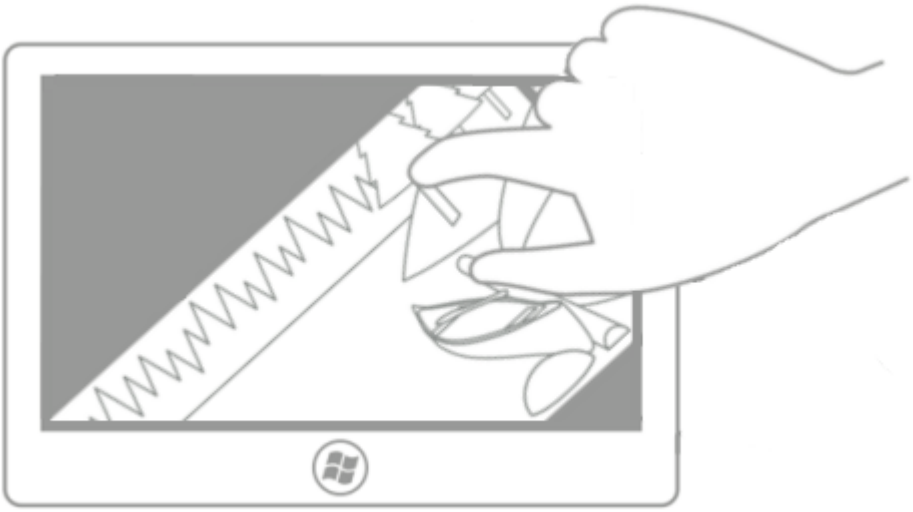


Note Intuitively, and in most cases, the rotation point is one of the two touch points unless the user can specify a rotation point unrelated to the contact points (for example, in a drawing or layout application). The following images demonstrate how the user experience can be degraded if the rotation point is not constrained in this way.

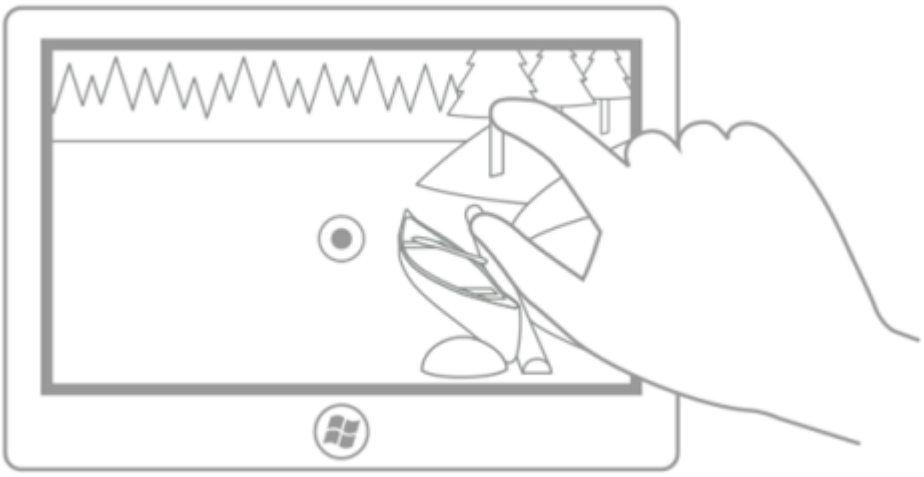
This first picture shows the initial (thumb) and secondary (index finger) touch points: the index finger is touching a tree and the thumb is touching a log.



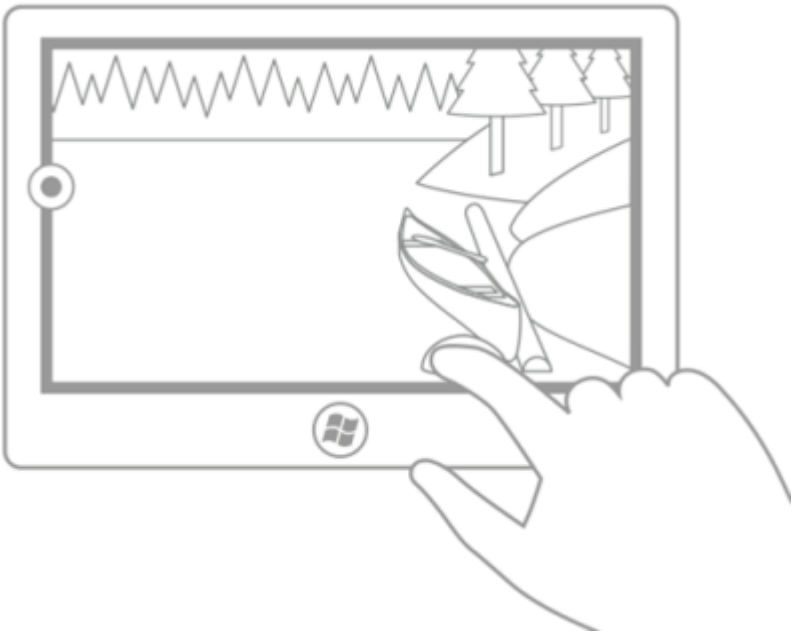
In this second picture, rotation is performed around the initial (thumb) touch point. After the rotation, the index finger is still touching the tree trunk and the thumb is still touching the log (the rotation point).



In this third picture, the center of rotation has been defined by the application (or set by the user) to be the center point of the picture. After the rotation, because the picture did not rotate around one of the fingers, the illusion of direct manipulation is broken (unless the user has chosen this setting).



In this last picture, the center of rotation has been defined by the application (or set by the user) to be a point in the middle of the left edge of the picture. Again, unless the user has chosen this setting, the illusion of direct manipulation is broken in this case.



Windows 10 supports three types of rotation: free, constrained, and combined.

Type	Description
Free rotation	Free rotation enables a user to rotate content freely anywhere in a 360 degree arc. When the user releases the object, the object remains in the chosen position. Free rotation is useful for drawing and layout applications such as Microsoft PowerPoint, Word, Visio, and Paint; and Adobe Photoshop, Illustrator, and Flash.

Type	Description
Constrained rotation	Constrained rotation supports free rotation during the manipulation but enforces snap points at 90 degree increments (0, 90, 180, and 270) upon release. When the user releases the object, the object automatically rotates to the nearest snap point. Constrained rotation is the most common method of rotation, and it functions in a similar way to scrolling content. Snap points let a user be imprecise and still achieve their goal. Constrained rotation is useful for applications such as web browsers and photo albums.
Combined rotation	Combined rotation supports free rotation with zones (similar to rails in Guidelines for panning) at each of the 90 degree snap points enforced by constrained rotation. If the user releases the object outside of one of 90 degree zones, the object remains in that position; otherwise, the object automatically rotates to a snap point. **Note** A user interface rail is a feature in which an area around a target constrains movement towards some specific value or location to influence its selection.

Guidelines for touch targets

Article • 10/04/2021

All interactive UI elements in your Windows application must be large enough for users to accurately access and use, regardless of device type or input method.

Supporting touch input (and the relatively imprecise nature of the touch contact area) requires further optimization with respect to target size and control layout as the larger, more complex set of input data reported by the touch digitizer is used to determine the user's intended (or most likely) target.

All UWP controls have been designed with default touch target sizes and layouts that enable you to build visually balanced and appealing apps that are comfortable, easy to use, and inspire confidence.

In this topic, we describe these default behaviors so you can design your app for maximum usability using both platform controls and custom controls (should your app require them).

> **Important APIs**: Windows.UI.Core, Windows.UI.Input, Windows.UI.Xaml.Input

Fluent Standard sizing

Fluent Standard sizing was created to provide a balance between information density and user comfort. Effectively, all items on the screen align to a 40x40 effective pixels (epx) target, which lets UI elements align to a grid and scale appropriately based on system level scaling.

> ⓘ **Note**
>
> For more info on effective pixels and scaling, see **Screen sizes and breakpoints**
>
> For more info on system level scaling, see **Alignment, margin, padding**.

Fluent Compact sizing

Applications can display a higher level of information density with *Fluent Compact sizing*. Compact sizing aligns UI elements to a 32x32 epx target, which lets UI elements to align to a tighter grid and scale appropriately based on system level scaling.

Examples

Compact sizing can be applied at the page or grid level.

Page level

XAML

```
<Page.Resources>
    <ResourceDictionary Source="ms-
appx:///Microsoft.UI.Xaml/DensityStyles/Compact.xaml" />
</Page.Resources>
```

Grid level

XAML

```
<Grid>
    <Grid.Resources>
        <ResourceDictionary Source="ms-
appx:///Microsoft.UI.Xaml/DensityStyles/Compact.xaml" />
    </Grid.Resources>
</Grid>
```

Target size

In general, set your touch target size to 7.5mm square range (40x40 pixels on a 135 PPI display at a 1.0x scaling plateau). Typically, UWP controls align with 7.5mm touch target (this can vary based on the specific control and any common usage patterns). See Control size and density for more detail.

These target size recommendations can be adjusted as required by your particular scenario. Here are some things to consider:

- Frequency of Touches - consider making targets that are repeatedly or frequently pressed larger than the minimum size.
- Error Consequence - targets that have severe consequences if touched in error should have greater padding and be placed further from the edge of the content area. This is especially true for targets that are touched frequently.
- Position in the content area.
- Form factor and screen size.
- Finger posture.

- Touch visualizations.

Guidelines for visual feedback

Article • 06/24/2021

Use visual feedback to show users when their interactions are detected, interpreted, and handled. Visual feedback can help users by encouraging interaction. It indicates the success of an interaction, which improves the user's sense of control. It also relays system status and reduces errors.

> **Important APIs**: Windows.Devices.Input, Windows.UI.Input, Windows.UI.Core

Recommendations

- Try to limit modifications of a control template to those directly related to your design intent, as extensive changes can impact the performance and accessibility of both the control and your application.
  - See XAML styles for more info on customizing the properties of a control, including visual state properties.
  - See the UserControl Class for details on making changes to a control template
  - Consider creating your own custom templated control if you need to make significant changes to a control template. For an example of a custom templated control, see the Custom Edit Control sample.
- Don't use touch visualizations in situations where they might interfere with the use of the app. For more info, see **ShowGestureFeedback**.
- Don't display feedback unless it is absolutely necessary. Keep the UI clean and uncluttered by not showing visual feedback unless you are adding value that is not available elsewhere.
- Try not to dramatically customize the visual feedback behaviors of the built-in Windows gestures, as this can create an inconsistent and confusing user experience.

Additional usage guidance

Contact visualizations are especially critical for touch interactions that require accuracy and precision. For example, your app should clearly indicate the location of a tap to let a user know if they missed their target, how much they missed it by, and what adjustments they must make.

Using the default XAML platform controls available ensures that your app works correctly on all devices and in all input situations. If your app features custom

interactions that require customized feedback, you should ensure the feedback is appropriate, spans input devices, and doesn't distract a user from their task. This can be a particular issue in game or drawing apps, where the visual feedback might conflict with or obscure critical UI.

> **ⓘ Important**
>
> We don't recommend changing the interaction behavior of the built-in gestures.

Feedback Across Devices

Visual feedback is generally dependent on the input device (touch, touchpad, mouse, pen/stylus, keyboard, and so on). For example, the built-in feedback for a mouse usually involves moving and changing the cursor, while touch and pen require contact visualizations, and keyboard input and navigation uses focus rectangles and highlighting.

Use ShowGestureFeedback to set feedback behavior for the platform gestures.

If customizing feedback UI, ensure you provide feedback that supports, and is suitable for, all input modes.

Here are some examples of built-in contact visualizations in Windows.

Expand table

			Touch visualization	Mouse/touchpad visualization	Pen visualization	Keyboard visualization

High Visibility Focus Visuals

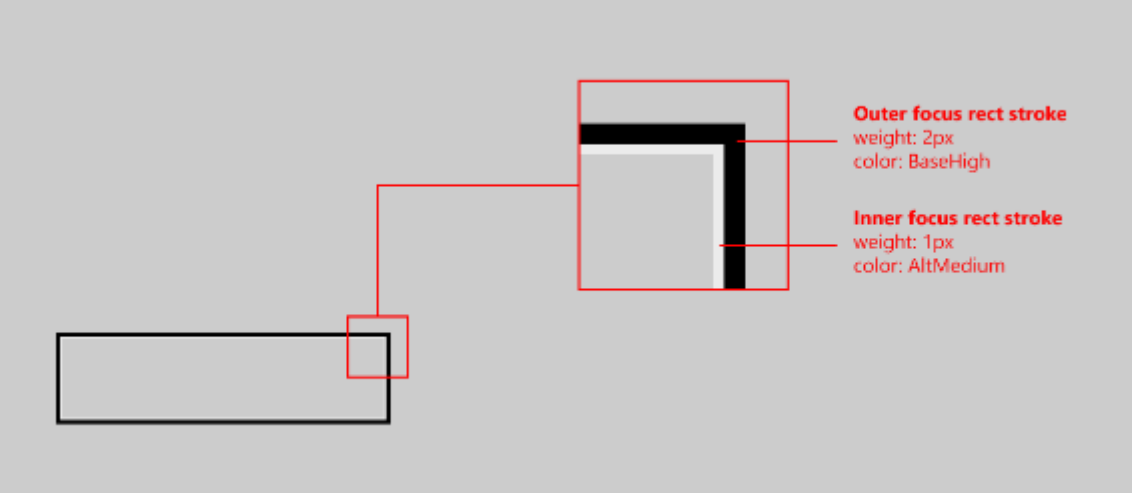
All Windows apps sport a more defined focus visual around interactable controls within the application. These new focus visuals are fully customizable as well as disableable when needed.

For the **10-foot experience** typical of Xbox and TV usage, Windows supports **Reveal focus**, a lighting effect that animates the border of focusable elements, such as a button, when they get focus through gamepad or keyboard input.

Color Branding & Customizing

Border Properties

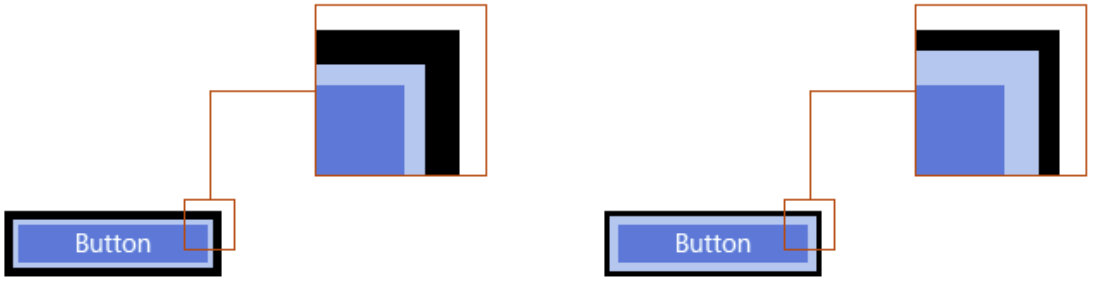
There are two parts to the high visibility focus visuals: the primary border and the secondary border. The primary border is **2px** thick, and runs around the *outside* of the secondary border. The secondary border is **1px** thick and runs around the *inside* of the primary border.



To change the thickness of either border type (primary or secondary) use the **FocusVisualPrimaryThickness** or **FocusVisualSecondaryThickness**, respectively:

XAML

```
<Slider Width="200" FocusVisualPrimaryThickness="5"
FocusVisualSecondaryThickness="2"/>
```



The margin is a property of type **Thickness**, and therefore the margin can be customized to appear only on certain sides of the control. See below:

The margin is the space between the control's visual bounds and the start of the focus visuals *secondary border*. The default margin is **1px** away from the control bounds. You can edit this margin on a per-control basis, by changing the **FocusVisualMargin** property:

```
XAML
<Slider Width="200" FocusVisualMargin="-5"/>
```

A negative margin will push the border away from the center of the control, and a positive margin will move the border closer to the center of the control.

To turn off focus visuals on the control entirely, simply disabled **UseSystemFocusVisuals**:

```
XAML
<Slider Width="200" UseSystemFocusVisuals="False"/>
```

The thickness, margin, or whether or not the app-developer wishes to have the focus visuals at all, is determined on a per-control basis.

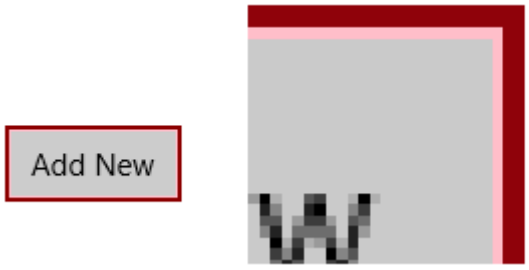
Color Properties

There are only two color properties for the focus visuals: the primary border color, and the secondary border color. These focus visual border colors can be changed per-control on a page level, and globally on an app-wide level:

To brand focus visuals app-wide, override the system brushes:

```
XAML
```

```
<SolidColorBrush x:Key="SystemControlFocusVisualPrimaryBrush"
Color="DarkRed"/>
<SolidColorBrush x:Key="SystemControlFocusVisualSecondaryBrush"
Color="Pink"/>
```



To change the colors on a per-control basis, just edit the focus visual properties on the desired control:

XAML

```
<Slider Width="200" FocusVisualPrimaryBrush="DarkRed"
FocusVisualSecondaryBrush="Pink"/>
```

Usability for Windows apps

Article • 05/13/2022

It's the little touches, an extra attention to detail, that can transform a good user experience into a truly inclusive user experience that meets the needs of users around the globe.

The design and coding instructions in this section can make your Windows app more inclusive by adding accessibility features, enabling globalization and localization, enabling users to customize their experience, and providing help when users need it.

Accessibility

Accessibility is about making your app usable by people who have limitations that prevent or impede the use of conventional user interfaces. For some situations, accessibility requirements are imposed by law. However, it's a good idea to address accessibility issues regardless of legal requirements so that your apps have the largest possible audience.

Accessibility portal

App settings

App settings let you the user customize your app, optimizing it for their individual needs and preferences. Providing the right settings and storing them properly can make a great user experience even better.

Guidelines

Best practices for creating and displaying app settings.

Store and retrieve app data

How to store and retrieve local, roaming, and temporary app data.

Globalization and localization

Windows is used worldwide by audiences that are diverse in terms of language, region, and culture. Your users speak a variety of different languages and in a variety of different

countries and regions. Some users speak more than one language. So, your app runs on configurations that involve many permutations of language, region, and culture system settings. Increase the potential market for your app by designing it to be readily adaptable, using *globalization* and *localization*.

Globalization and localization portal

In-app help

No matter how well you've designed your app, some users will need a little extra help.

Guidelines for app help

Applications can be complex, and providing effective help for your users can greatly improve their experience.

Instructional UI

Sometimes it can be helpful to teach the user about functions in your app that might not be obvious to them, such as specific touch interactions. In these cases, you need to present instructions to the user through the UI so they can discover and use features they might have missed.

In-app help

Most of the time, it's best for help to be displayed within the app, and to be displayed when the user chooses to view it. Consider the following guidelines when creating in-app help.

External help

Most of the time, it's best for help to be displayed within the app, and to be displayed when the user chooses to view it. Consider the following guidelines when creating in-app help.

Accessibility

Article • 05/13/2022

Accessibility is about building experiences that make your Windows application usable by people who use technology in a wide range of environments and approach your UI with a range of needs and experiences. For some situations, accessibility requirements are imposed by law. However, it's a good idea to address accessibility issues regardless of legal requirements so that your apps have the largest possible audience.

> There's also a Microsoft Store declaration regarding accessibility for your app!

Accessibility overview

Article • 03/31/2023

This article is an overview of the concepts and technologies related to accessibility scenarios for Windows apps.

Accessibility and your app

There are many possible disabilities or impairments, including limitations in mobility, vision, color perception, hearing, speech, cognition, and literacy. However, you can address most requirements by following the guidelines offered here. This means providing:

- Support for keyboard interactions and screen readers.
- Support for user customization, such as font, zoom setting (magnification), color, and high-contrast settings.
- Alternatives or supplements for parts of your UI.

Controls for XAML provide built-in keyboard support and support for assistive technologies such as screen readers, which take advantage of accessibility frameworks that already support UWP apps, HTML, and other UI technologies. This built-in support enables a basic level of accessibility that you can customize with very little work, by setting just a handful of properties. If you are creating your own custom XAML components and controls, you can also add similar support to those controls by using the concept of an *automation peer*.

In addition, data binding, style, and template features make it easy to implement support for dynamic changes to display settings and text for alternative UIs.

UI Automation

Accessibility support comes primarily from the integrated support for the Microsoft UI Automation framework. That support is provided through base classes and the built-in behavior of the class implementation for control types, and an interface representation of the UI Automation provider API. Each control class uses the UI Automation concepts of automation peers and automation patterns that report the control's role and content to UI Automation clients. The app is treated as a top-level window by UI Automation, and through the UI Automation framework all the accessibility-relevant content within that app window is available to a UI Automation client. For more info about UI Automation, see UI Automation Overview.

Assistive technology

Many user accessibility needs are met by assistive technology products installed by the user or by tools and settings provided by the operating system. This includes functionality such as screen readers, screen magnification, and high-contrast settings.

Assistive technology products include a wide variety of software and hardware. These products work through the standard keyboard interface and accessibility frameworks that report information about the content and structure of a UI to screen readers and other assistive technologies. Examples of assistive technology products include:

- The On-Screen Keyboard, which enables people to use a pointer in place of a keyboard to type text.
- Voice-recognition software, which converts spoken words into typed text.
- Screen readers, which convert text into spoken words or other forms such as Braille.
- The Narrator screen reader, which is specifically part of Windows. Narrator has a touch mode, which can perform screen reading tasks by processing touch gestures, for when there is no keyboard available.
- Programs or settings that adjust the display or areas of it, for example high contrast themes, dots per inch (dpi) settings of the display, or the Magnifier tool.

Apps that have good keyboard and screen reader support usually work well with various assistive technology products. In many cases, a UWP app works with these products without additional modification of information or structure. However, you may want to modify some settings for optimal accessibility experience or to implement additional support.

Some of the options that you can use for testing basic accessibility scenarios with assistive technologies are listed in Accessibility testing.

Screen reader support and basic accessibility information

Screen readers provide access to the text in an app by rendering it in some other format, such as spoken language or Braille output. The exact behavior of a screen reader depends on the software and on the user's configuration of it.

For example, some screen readers read the entire app UI when the user starts or switches to the app being viewed, which enables the user to receive all of the available informational content before attempting to navigate it. Some screen readers also read

the text associated with an individual control when it receives focus during tab navigation. This enables users to orient themselves as they navigate among the input controls of an application. Narrator is an example of a screen reader that provides both behaviors, depending on user choice.

The most important information that a screen reader or any other assistive technology needs in order to help users understand or navigate an app is an *accessible name* for the element parts of the app. In many cases, a control or element already has an accessible name that is calculated from other property values that you have otherwise provided. The most common case in which you can use an already-calculated name is with an element that supports and displays inner text. For other elements, you sometimes need to account for other ways to provide an accessible name by following best practices for element structure. And sometimes you need to provide a name that is explicitly intended as the accessible name for app accessibility. For a listing of how many of these calculated values work in common UI elements, and for more info about accessible names in general, see Basic accessibility information.

There are several other automation properties available (including the keyboard properties described in the next section). However, not all screen readers support all automation properties. In general, you should set all appropriate automation properties and test to provide the widest possible support for screen readers.

Keyboard support

To provide good keyboard support, you must ensure that every part of your application can be used with a keyboard. If your app uses mostly the standard controls and doesn't use any custom controls, you are most of the way there already. The basic XAML control model provides built-in keyboard support including tab navigation, text input, and control-specific support. The elements that serve as layout containers (such as panels) use the layout order to establish a default tab order. That order is often the correct tab order to use for an accessible representation of the UI. If you use **ListBox** and **GridView** controls to display data, they provide built-in arrow-key navigation. Or if you use a **Button** control, it already handles the Spacebar or Enter keys for button activation.

For more info about all the aspects of keyboard support, including tab order and key-based activation or navigation, see Keyboard accessibility.

Media and captioning

You typically display audiovisual media through a **MediaElement** object. You can use **MediaElement** APIs to control the media playback. For accessibility purposes, provide

controls that enable users to play, pause, and stop the media as needed. Sometimes, media includes additional components that are intended for accessibility, such as captioning or alternative audio tracks that include narrative descriptions.

Accessible text

Three main aspects of text are relevant to accessibility:

- Tools must determine whether the text is to be read as part of a tab-sequence traversal or only as part of an overall document representation. You can help control this determination by choosing the appropriate element for displaying the text or by adjusting properties of those text elements. Each text element has a specific purpose, and that purpose often has a corresponding UI Automation role. Using the wrong element can result in reporting the wrong role to UI Automation and creating a confusing experience for an assistive technology user.
- Many users have sight limitations that make it difficult for them to read text unless it has adequate contrast against the background. How this impacts the user is not intuitive for app designers who do not have that sight limitation. For example, for color-blind users, poor color choices in the design can prevent some users from being able to read the text. Accessibility recommendations that were originally made for web content define standards for contrast that can avoid these problems in apps as well. For more info, see Accessible text requirements.
- Many users have difficulty reading text that is simply too small. You can prevent this issue by making the text in your app's UI reasonably large in the first place. However, that's challenging for apps that display large quantities of text, or text interspersed with other visual elements. In such cases, make sure that the app correctly interacts with the system features that can scale up the display, so that any text in apps scales up along with it. (Some users change dpi values as an accessibility option. That option is available from **Make things on the screen larger** in **Ease of Access**, which redirects to a **Control Panel** UI for **Appearance and Personalization** / **Display**.)

Supporting high-contrast themes

UI controls use a visual representation that is defined as part of a XAML resource dictionary of themes. One or more of these themes is specifically used when the system is set for high contrast. When the user switches to high contrast, by looking up the appropriate theme from a resource dictionary dynamically, all your UI controls will use an appropriate high-contrast theme too. Just make sure that you haven't disabled the themes by specifying an explicit style or using another styling technique that prevents

the high-contrast themes from loading and overriding your style changes. For more info, see High-contrast themes.

Design for alternative UI

When you design your apps, consider how they may be used by people with limited mobility, vision, and hearing. Because assistive technology products make extensive use of standard UI, it is particularly important to provide good keyboard and screen-reader support even if you make no other adjustments for accessibility.

In many cases, you can convey essential information by using multiple techniques to widen your audience. For example, you can highlight information using both icon and color information to help users who are color blind, and you can display visual alerts along with sound effects to help users who are deaf or hard of hearing.

If necessary, you can provide alternative, accessible user interface elements that completely remove nonessential elements and animations, and provide other simplifications to streamline the user experience. The following code example demonstrates how to display one **UserControl** instance in place of another depending on a user setting.

XAML

XML

```
<StackPanel x:Name="LayoutRoot" Background="White">

  <CheckBox x:Name="ShowAccessibleUICheckBox"
Click="ShowAccessibleUICheckBox_Click">
    Show Accessible UI
  </CheckBox>

  <UserControl x:Name="ContentBlock">
    <local:ContentPage/>
  </UserControl>

</StackPanel>
```

Visual Basic

VB

```
Private Sub ShowAccessibleUICheckBox_Click(ByVal sender As Object,
    ByVal e As RoutedEventArgs)

    If (ShowAccessibleUICheckBox.IsChecked.Value) Then
```

```
        ContentBlock.Content = New AccessibleContentPage()
    Else
        ContentBlock.Content = New ContentPage()
    End If
End Sub
```

C#

```
C#

private void ShowAccessibleUICheckBox_Click(object sender, RoutedEventArgs
e)
{
    if ((sender as CheckBox).IsChecked.Value)
    {
        ContentBlock.Content = new AccessibleContentPage();
    }
    else
    {
        ContentBlock.Content = new ContentPage();
    }
}
```

Verification and publishing

For more info about accessibility declarations and publishing your app, see Accessibility in the Store.

> ⓘ **Note**
>
> Declaring the app as accessible is only relevant to the Microsoft Store.

Assistive technology support in custom controls

When you create a custom control, we recommend that you also implement or extend one or more **AutomationPeer** subclasses to provide accessibility support. In some cases, so long as you use the same peer class as was used by the base control class, the automation support for your derived class is adequate at a basic level. However, you should test this, and implementing a peer is still recommended as a best practice so that the peer can correctly report the class name of your new control class. Implementing a custom automation peer has a few steps involved. For more info, see Custom automation peers.

Assistive technology support in apps that support XAML / Microsoft DirectX interop

Microsoft DirectX content that's hosted in a XAML UI (using **SwapChainPanel** or **SurfaceImageSource**) is not accessible by default. The XAML SwapChainPanel DirectX interop sample shows how to create UI Automation peers for the hosted DirectX content. This technique makes the hosted content accessible through UI Automation.

Examples

> **Tip**

Open the WinUI 3 Gallery app and see the following Accessibility principles in action:

- **Screen reader support**
- **Keyboard support**
- **Color contrast**

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Designing inclusive software for Windows

Article • 05/13/2022

Learn about evolving inclusive design with Windows apps for Windows. Design and build inclusive software with accessibility in mind.

At Microsoft, we're evolving our design principles and practices. These inform how our experiences look, feel, function, and behave. We're elevating our perspective.

This new design philosophy is called inclusive design. The idea is to design software with everyone in mind from the very beginning. This is in contrast to viewing accessibility as a technology you bolt on at the end of the development process in order to satisfy some small group of users.

"We define disability as a mismatch between the needs of the individual and the service, product or environment offered. Anyone can experience a disability. It is a common human trait to be excluded." - from the Inclusive video

Inclusive design creates better products for everyone. It's about considering the full range of human diversity. Consider the curb cutouts that you now find on most street corner sidewalks. They were clearly intended to be used by people in wheelchairs. But now nearly everyone uses them, including people with baby strollers, bicyclists, skateboarders. Even pedestrians will often use curb cutouts because they are there and provide a better experience. The television remote control could be considered an assistive technology (AT) for someone with physical limitations. And yet, today it is nearly impossible to buy a television without one. Before children learn to tie their shoes, they can wear slip-on or easy fastening shoes. Shoes that are easy to put on and take off are often preferred in cultures where shoes are removed before entering a home. They are also better for people with dexterity issues such as arthritis or even a temporarily broken wrist.

Inclusive design principles

The following 4 principles are guiding Microsoft's shift to inclusive design:

Think universal: We focus on what unifies people — human motivations, relationships, and abilities. This drives us to consider the broader social impact of our work. The result is an experience that has a diversity of ways for all people to participate.

Make it personal: Next, we challenge ourselves to create emotional connections. Human-to-human interactions can inspire better human-to-technology interaction. A person's unique circumstances can improve a design for everyone. The result is an experience that feels like it was created for one person.

Keep it simple: We start with simplicity as the ultimate unifier. When we reduce clutter people know what to do next. They're inspired to move forward into spaces that are clean, light, and open. The result is an experience that's honest and timeless.

Create delight: Delightful experiences evoke wonder and discovery. Sometimes it's magical. Sometimes it's a detail that's just right. We design these moments to feel like a welcomed change in tempo. The result is an experience that has momentum and flow.

Inclusive design users

There are essentially two types of users of assistive technology (AT):

1. Those who need it, because of disabilities or impairments, age-related conditions, or temporary conditions (such as limited mobility from a broken limb)
2. Those who use it out of preference, for a more comfortable or convenient computing experience

The majority of computer users (54 per-cent) are aware of some form of assistive technology, and 44 percent of computer users use some form of it, but many of them are not using AT that would benefit them (Forrester 2004).

A 2003-2004 study commissioned by Microsoft and conducted by Forrester Research found that over half — 57 percent — of computer users in the United States between the ages of 18 and 64 could benefit from assistive technology. Most of these users did not identify themselves as having a disability or being impaired but expressed certain task-related difficulties or impairments when using a computer. Forrester (2003) also found the following number of users with these specific difficulties: One in four experiences a visual difficulty. One in four experiences pain in the wrists or hands. One in five experiences hearing difficulty.

Besides permanent disabilities, the severity and types of difficulties an individual experiences can vary throughout their life. There is no such thing as a normal human. Our capabilities are always changing. Margaret Meade said, "We are all unique. Being all unique makes us all the same."

Microsoft is dedicated to conducting computer science and software engineering research with goals to enhance the computing experience and invent novel computing

technologies. See Current Microsoft Research and Development Projects aimed at making the computer more accessible, and easier to see, hear, and interact with.

Practical design steps

If you're all in, then this section is for you. It describes the practical design steps to consider when implementing inclusive design for your app.

Describe the target audience

Define the potential users of your app. Think through all of their different abilities and characteristics. For example, age, gender, language, deaf or hard of hearing users, visual impairments, cognitive abilities, learning style, mobility restrictions, and so on. Is your design meeting their individual needs?

Talk to actual humans with specific needs

Meet with potential users who have diverse characteristics. Make sure you are considering all of their needs when designing your app. For example, Microsoft discovered that deaf users were turning off toast notifications on their Xbox consoles. When we asked actual deaf users about this, we learned that toast notifications were obscuring a section of closed captioning. The fix was to display the toast slight higher on the screen. This was a simple solution that was not necessarily obvious from the telemetry data that initially revealed the behavior.

Choose a development framework wisely

In the design stage, the development framework you will use (i.e. UWP, Win32, web) is critical to the development of your product. If you have the luxury of choosing your framework, think about how much effort it will take to create your controls within the framework. What are the default or built-in accessibility properties that come with it? Which controls will you need to customize? When choosing your framework, you are essentially choosing how much of the accessibility controls you will get “for free” (that is, how much of the controls are already built-in) and how much will require additional development costs because of control customizations.

Use standard Windows controls whenever possible. These controls are already enabled with the technology necessary to interface with assistive technologies.

Design a logical hierarchy for your controls

Once you have your framework, design a logical hierarchy to map out your controls. The logical hierarchy of your app includes the layout and tab order of controls. When assistive technology (AT) programs, such as screen readers, read your UI, visual presentation is not sufficient; you must provide a programmatic alternative that makes sense structurally to your users. A logical hierarchy can help you do that. It is a way of studying the layout of your UI and structuring each element so that users can understand it. A logical hierarchy is mainly used:

1. To provide programs context for the logical (reading) order of the elements in the UI
2. To identify clear boundaries between custom controls and standard controls in the UI
3. To determine how pieces of the UI interact together

A logical hierarchy is a great way to address any potential usability issues. If you cannot structure the UI in a relatively simple manner, you may have problems with usability. A logical representation of a simple dialog box should not result in pages of diagrams. For logical hierarchies that become too deep or too wide, you may need to redesign your UI. For more information, download the Engineering Software for Accessibility eBook.

Design appropriate visual UI settings

When designing the visual UI, ensure that your product has a high contrast setting, uses the default system fonts and smoothing options, correctly scales to the dots per inch (dpi) screen settings, has default text with at least a 5:1 contrast ratio with the background, and has color combinations that will be easy for users with color deficiencies to differentiate.

High contrast setting

One of the built-in accessibility features in Windows is High Contrast mode, which heightens the color contrast of text and images. For some people, increasing the contrast in colors reduces eyestrain and makes it easier to read. When you verify your UI in high contrast mode, you want to check that controls, such as links, have been coded consistently and with system colors (not with hard-coded colors) to ensure that they will be able to see all the controls on the screen that a user not using high contrast would see.

System font settings

To ensure readability and minimize any unexpected distortions to the text, make sure that your product always adheres to the default system fonts and uses the anti-aliasing and smoothing options. If your product uses custom fonts, users may face significant readability issues and distractions when they customize the presentation of their UI (through the use of a screen reader or by using different font styles to view your UI, for instance).

High DPI resolutions

For users with vision impairments, having a scalable UI is important. User interfaces that do not scale correctly in high dots-per-inch (DPI) resolutions may cause important components to overlap or hide other components and can become inaccessible.

Color contrast ratio

The updated Section 508 of the Americans with Disability Act (ADA), as well as other legislations, requires that the default color contrasts between text and its background must be 5:1. For large texts (18-point font sizes, or 14 points and bolded) the required default contrast is 3:1.

Color combinations

About 7 percent of males (and less than 1 percent of females) have some form of color deficiency. Users with colorblindness have problems distinguishing between certain colors, so it is important that color alone is never used to convey status or meaning in an application. As for decorative images (such as icons or backgrounds), color combinations should be chosen in a manner that maximizes the perception of the image by colorblind users. If you design using these color recommendations from the beginning, your app will already be taking significant steps toward being inclusive.

Summary — seven steps for inclusive design

In summary, follow these seven steps to ensure your software is inclusive.

1. Decide if inclusive design is an important aspect to your software. If it is, learn and appreciate how it enables real users to live, work, and play, to help guide your design.
2. As you design solutions for your requirements, use controls provided by your framework (standard controls) as much as possible, and avoid any unnecessary effort and costs of custom controls.

3. Design a logical hierarchy for your product, noting where the standard controls, any custom controls, and keyboard focus are in the UI.
4. Design useful system settings (such as keyboard navigation, high contrast, and high dpi) into your product.
5. Implement your design, using the Microsoft accessibility developer hub and your framework's accessibility specification as a reference point.
6. Test your product with users who have functional needs to ensure they will be able to take advantage of the inclusive design techniques implemented in it.
7. Deliver your finished product and document your implementation for those who may work on the project after you.

Developing inclusive Windows apps

Article • 05/13/2022

This article discusses how to develop accessible Windows apps. Specifically, it assumes that you understand how to design the logical hierarchy for your app. Learn to develop accessible Windows apps that include keyboard navigation, color and contrast settings, and support for assistive technologies.

If you have not yet done so, please start by reading Designing inclusive software.

There are three things you should do to make sure that your app is accessible:

1. Expose your UI elements to programmatic access.
2. Ensure that your app supports keyboard navigation for people who are unable to use a mouse or touchscreen.
3. Make sure that your app supports accessible color and contrast settings.

Programmatic access

Programmatic access is critical for creating accessibility in apps. This is achieved by setting the accessible name (required) and description (optional) for content and interactive UI elements in your app. This ensures that UI controls are exposed to assistive technology (AT) such as screen readers (for example, Narrator) or alternative output devices (such as Braille displays). Without programmatic access, the APIs for assistive technology cannot interpret information correctly, leaving the user unable to use the products sufficiently, or forcing the AT to use undocumented programming interfaces or techniques never intended to be used as an accessibility interface. When UI controls are exposed to assistive technology, the AT is able to determine what actions and options are available to the user.

For more information about making your app UI elements available to assistive technologies (AT), see Expose basic accessibility information.

Keyboard navigation

For users who are blind or have mobility issues, being able to navigate the UI with a keyboard is extremely important. However, only those UI controls that require user interaction to function should be given keyboard focus. Components that don't require an action, such as static images, do not need keyboard focus.

It is important to remember that unlike navigating with a mouse or touch, keyboard navigation is linear. When considering keyboard navigation, think about how your user will interact with your product and what the logical navigation will be. In Western cultures, people read from left to right, top to bottom. It is, therefore, common practice to follow this pattern for keyboard navigation.

When designing keyboard navigation, examine your UI, and think about these questions:

- How are the controls laid out or grouped in the UI?
- Are there a few significant groups of controls?
  - If yes, do those groups contain another level of groups?
- Among peer controls, should navigation be done by tabbing around, or via special navigation (such as arrow keys), or both?

The goal is to help the user understand how the UI is laid out and identify the controls that are actionable. If you are finding that there are too many tab stops before the user completes the navigation loop, consider grouping related controls together. Some controls that are related, such as a hybrid control, may need to be addressed at this early exploration stage. After you begin to develop your product, it is difficult to rework the keyboard navigation, so plan carefully and plan early!

To learn more about keyboard navigation among UI elements, see Keyboard accessibility.

Also, the Engineering Software for Accessibility eBook has an excellent chapter on this subject titled *Designing the Logical Hierarchy*.

Color and contrast

One of the built-in accessibility features in Windows is the High Contrast mode, which heightens the color contrast of text and images on the computer screen. For some people, increasing the contrast in colors reduces eyestrain and makes it easier to read. When you verify your UI in high contrast, you want to check that controls have been coded consistently and with system colors (not with hard-coded colors) to ensure that they will be able to see all the controls on the screen that a user not using high contrast would see.

XAML

```
XAML
```

```
<Button Background="{ThemeResource ButtonBackgroundThemeBrush}">OK</Button>
```

For more information about using system colors and resources, see XAML theme resources.

As long as you haven't overridden system colors, a UWP app supports high-contrast themes by default. If a user has chosen that they want the system to use a high-contrast theme from system settings or accessibility tools, the framework automatically uses colors and style settings that produce a high-contrast layout and rendering for controls and components in the UI.

For more information, see High-contrast themes.

If you have decided to use you own color theme instead of system colors, consider these guidelines:

Color contrast ratio – The updated Section 508 of the Americans with Disability Act, as well as other legislation, requires that the default color contrasts between text and its background must be 5:1. For large text (18-point font sizes, or 14 points and bolded), the required default contrast is 3:1.

Color combinations – About 7 percent of males (and less than 1 percent of females) have some form of color deficiency. Users with colorblindness have problems distinguishing between certain colors, so it is important that color alone is never used to convey status or meaning in an application. As for decorative images (such as icons or backgrounds), color combinations should be chosen in a manner that maximizes the perception of the image by colorblind users.

Accessibility checklist

Following is an abbreviated version of the accessibility checklist:

1. Set the accessible name (required) and description (optional) for content and interactive UI elements in your app.
2. Implement keyboard accessibility.
3. Visually verify your UI to ensure that the text contrast is adequate, elements render correctly in the high-contrast themes, and colors are used correctly.
4. Run accessibility tools, address reported issues, and verify the screen reading experience. (See Accessibility testing topic.)
5. Make sure your app manifest settings follow accessibility guidelines.
6. Declare your app as accessible in the Microsoft Store. (See the Accessibility in the store topic.)

For more detail, please see the full Accessibility checklist topic.

Accessibility testing

Article • 08/13/2022

This topic describes various tools and procedures to help you verify the accessibility implementation of your Windows and web applications.

Successful user experiences

Programmatic access and keyboard access are critical requirements for supporting accessibility in your application. Testing the accessibility of your Windows applications, assistive technology (AT) tools, and UI frameworks is crucial to ensure a successful user experience for people with various disabilities and limitations (including vision, learning, dexterity/mobility, and language/communication disabilities), or those who simply prefer using a keyboard.

Without adequate support for accessible technology (AT) such as screen-readers and on-screen keyboards, users with vision, learning, dexterity/mobility, and language/communication disabilities or limitations (and users who just prefer using the keyboard) could find it difficult, if not impossible, to use your application.

Accessibility testing tools

Accessibility Insights

Accessibility Insights helps developers find and fix accessibility issues in both websites and Windows applications.
https://www.youtube-nocookie.com/embed/XlvI91Q3c_8

- Accessibility Insights for Windows helps developers find and fix accessibility issues in Windows apps. The tool supports three primary scenarios:
  - **Live Inspect** lets developers verify that an element in an app has the right UI Automation properties simply by hovering over the element or setting keyboard focus on it.
  - **FastPass** - a lightweight, two-step process that helps developers identify common, high-impact accessibility issues in less than five minutes.
  - **Troubleshooting** allows you to diagnose and fix specific accessibility issues.
- Accessibility Insights for Web is an extension for Chrome and Microsoft Edge Insider that helps developers find and fix accessibility issues in web apps and sites. It supports two primary scenarios:

- **FastPass** - a lightweight, two-step process that helps developers identify common, high-impact accessibility issues in less than five minutes.
- **Assessment** - lets anyone verify that a web site is 100% compliant with accessibility standards and guidelines. Accessibility Insights also lets you review UI Automation elements, properties, control patterns, and events (similar to the Inspect and AccEvent legacy tools described in the following section).

Legacy testing tools

> **Note**
>
> The tools described here are still available in the Windows SDK, but we strongly recommend transitioning to **Accessibility Insights**.

The Windows Software Development Kit (SDK) includes several accessibility testing tools, including **AccScope**, **Inspect** and **UI Accessibility Checker**, among others.

You can launch the following accessibility testing tools either from a Microsoft Visual Studio command prompt or by navigating to the *bin* folder of wherever the Windows SDK is installed on your development machine.

AccScope

The **AccScope** Enables visual evaluation of an application's accessibility during the early design and development phases. AccScope is specifically intended for testing Narrator accessibility scenarios and uses the UI Automation information provided by an app to show where accessibility can be improved.

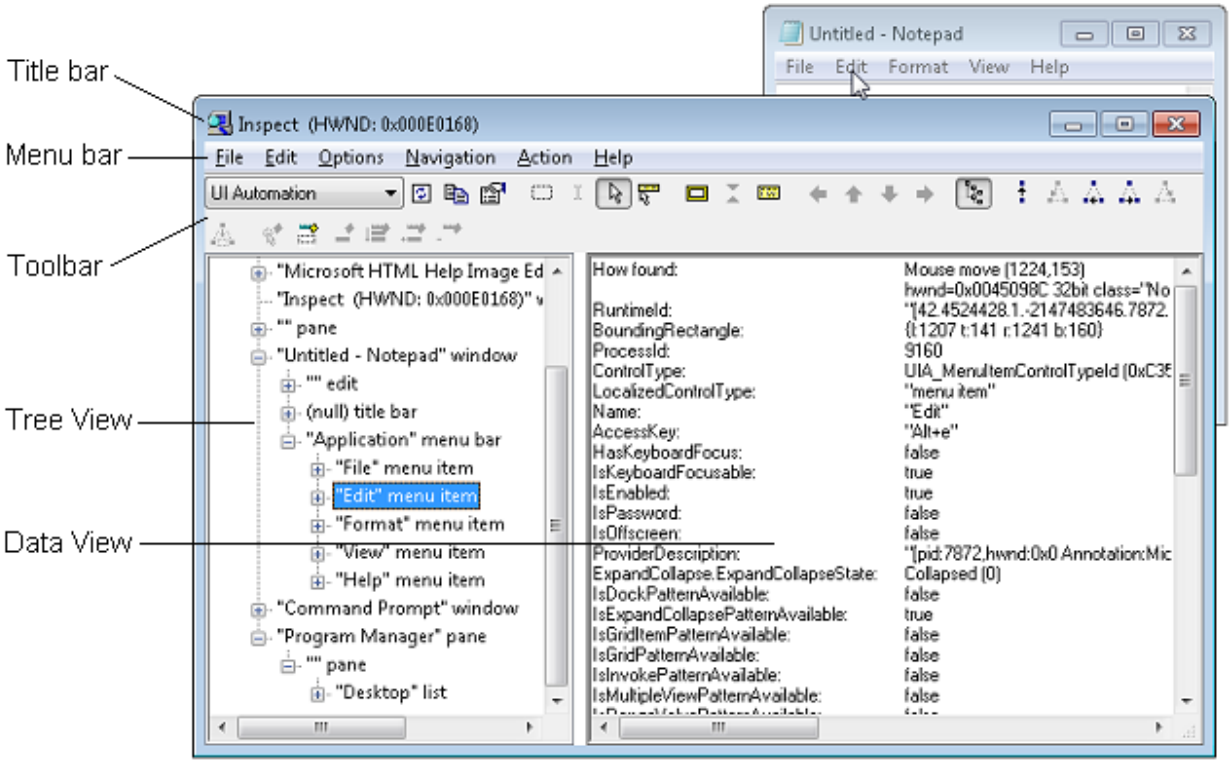
Inspect

Inspect enables you to select any UI element and view its accessibility data. You can view Microsoft UI Automation properties and control patterns and test the navigational structure of the automation elements in the UI Automation tree. It is especially useful for ensuring properties and control patterns are set correctly when extending a common control or creating a custom control.

Use **Inspect** as you develop the UI to verify how accessibility attributes are exposed in UI Automation. In some cases the attributes come from the UI Automation support that is already implemented for default XAML controls. In other cases the attributes come from

specific values that you have set in your XAML markup, as **AutomationProperties** attached properties.

The following image shows the **Inspect** tool querying the UI Automation properties of the **Edit** menu element in Notepad.



UI Accessibility Checker

UI Accessibility Checker (AccChecker) helps you discover potential accessibility issues at run time. AccChecker includes verification checks for UI Automation, Microsoft Active Accessibility, and Accessible Rich Internet Applications (ARIA). It can provide a static check for errors such as missing names, tree issues and more. It helps verify programmatic access and includes advanced features for automating accessibility testing. You can run **AccChecker** in UI or command line mode. To run the UI mode tool, open the *AccChecker* folder in the Windows SDK *bin* folder, run accccheckui.exe, and click the **Help** menu.

UI Automation Verify

UI Automation Verify (UIA Verify) is a framework for manual and automated testing of the UI Automation implementation in a control or application (results can be logged). **UIA Verify** can integrate into the test code and conduct regular, automated testing or spot checks of UI Automation scenarios and is useful for verifying that changes to applications with established features do not have new issues or regressions. **UIA Verify** can be found in the *UIAVerify* subfolder of the Windows SDK *bin* folder.

Accessible Event Watcher

Accessible Event Watcher (AccEvent) tests whether an app's UI elements fire proper UI Automation and Microsoft Active Accessibility events when UI changes occur. Changes in the UI can occur when the focus changes, or when a UI element is invoked, selected, or has a state or property change. AccEvent is typically used to debug issues and to validate that custom and extended controls are working correctly.

Accessibility testing procedures

Test keyboard accessibility

The best way to test your keyboard accessibility is to unplug your mouse or use the On-Screen Keyboard if you are using a tablet device. Test keyboard accessibility navigation by using the *Tab* key. You should be able to cycle through all interactive UI elements by using *Tab* key. For composite UI elements, verify that you can navigate among the parts of elements by using the arrow keys. For example, you should be able to navigate lists of items using keyboard keys. Finally, make sure that you can invoke all interactive UI elements with the keyboard once those elements have focus, typically by using the Enter or Spacebar key.

Verify the contrast ratio of visible text

Use color contrast tools to verify that the visible text contrast ratio is acceptable. The exceptions include inactive UI elements, and logos or decorative text that doesn't convey any information and can be rearranged without changing the meaning. See Accessible text requirements for more information on contrast ratio and exceptions. See Techniques for WCAG 2.0 G18 (Resources section) for tools that can test contrast ratios.

> **Note**
>
> Some of the tools listed by Techniques for WCAG 2.0 G18 can't be used interactively with a UWP app. You may need to enter foreground and background color values manually in the tool, make screen captures of app UI and then run the contrast ratio tool over the screen capture image, or run the tool while opening source bitmap files in an image editing program rather than while that image is loaded by the app.

Verify your app in high contrast

Use your app while a high-contrast theme is active to verify that all the UI elements display correctly. All text should be readable, and all images should be clear. Adjust the XAML theme-dictionary resources or control templates to correct any theme issues that come from controls. In cases where prominent high-contrast issues are not coming from themes or controls (such as from image files), provide separate versions to use when a high-contrast theme is active.

Verify your app with display settings

Use the system display options that adjust the display's dots per inch (dpi) value, and ensure that your app UI scales correctly when the dpi value changes. (Some users change dpi values as an accessibility option, it's available from **Ease of Access** as well as display properties.) If you find any issues, follow the Guidelines for layout scaling and provide additional resources for different scaling factors.

Verify main app scenarios by using Narrator

Use Narrator to test the screen reading experience for your app.

Use these steps to test your app using Narrator with a mouse and keyboard:

1. Start Narrator by pressing *Windows logo key* + *Ctrl* + *Enter*. In versions prior to Windows 10 version 1607, use *Windows logo key* + *Enter* to start Narrator.
2. Navigate your app with the keyboard by using the *Tab* key, the arrow keys, and the *Caps Lock* + *arrow keys*.
3. As you navigate your app, listen as Narrator reads the elements of your UI and verify the following:

    - For each control, ensure that Narrator reads all visible content. Also ensure that Narrator reads each control's name, any applicable state (checked, selected, and so on), and the control type (button, check box, list item, and so on).
    - If the element is interactive, verify that you can use Narrator to invoke its action by pressing *Caps Lock* + *Enter*.
    - For each table, ensure that Narrator correctly reads the table name, the table description (if available), and the row and column headings.

4. Press *Caps Lock* + *Shift* + *Enter* to search your app and verify that all of your controls appear in the search list, and that the control names are localized and readable.

5. Turn off your monitor and try to accomplish main app scenarios by using only the keyboard and Narrator. To get the full list of Narrator commands and shortcuts, press *Caps Lock + F1*.

Starting with Windows 10 version 1607, we introduced a new developer mode in Narrator. Turn on developer mode when Narrator is already running by pressing *Control + Caps Lock + F12*. When developer mode is enabled, the screen will be masked and will highlight only the accessible objects and the associated text that is exposed programmatically to Narrator. This gives a you a good visual representation of the information that is exposed to Narrator.

Use these steps to test your app using Narrator's touch mode:

> ⓘ **Note**
>
> Narrator automatically enters touch mode on devices that support 4+ contacts. Narrator doesn't support multi-monitor scenarios or multi-touch digitizers on the primary screen.

1. Get familiar with the UI and explore the layout.

    - **Navigate through the UI by using single-finger swipe gestures.** Use left or right swipes to move between items, and up or down swipes to change the category of items being navigated. Categories include all items, links, tables, headers, and so on. Navigating with single-finger swipe gestures is similar to navigating with *Caps Lock + Arrow*.
    - **Use tab gestures to navigate through focusable elements.** A three-finger swipe to the right or left is the same as navigating with *Tab* and *Shift + Tab* on a keyboard.
    - **Spatially investigate the UI with a single finger.** Drag a single finger up and down, or left and right, to have Narrator read the items under your finger. You can use the mouse as an alternative because it uses the same hit-testing logic as dragging a single finger.
    - **Read the entire window and all its contents with a three finger swipe up**. This is equivalent to using *Caps Lock + W*.

    If there is important UI that you cannot reach, you may have an accessibility issue.

2. Interact with a control to test its primary and secondary actions, and its scrolling behavior.

    Primary actions include things like activating a button, placing a text caret, and setting focus to the control. Secondary actions include actions such as selecting a

list item or expanding a button that offers multiple options.

- To test a primary action: Double tap, or press with one finger and tap with another.
- To test a secondary action: Triple tap, or press with one finger and double tap with another.
- To test scrolling behavior: Use two-finger swipes to scroll in the desired direction.

Some controls provide additional actions. To display the full list, enter a single four-finger tap.

If a control responds to the mouse or keyboard but does not respond to a primary or secondary touch interaction, the control might need to implement additional UI Automation control patterns.

You should also consider using the **AccScope** tool to test Narrator accessibility scenarios with your app. The **AccScope tool topic** describes how to configure **AccScope** to test Narrator scenarios.

Examine the UI Automation representation for your app

Several of the UI Automation testing tools mentioned previously provide a way to view your app in a way that deliberately does not consider what the app looks like, and instead represents the app as a structure of UI Automation elements. This is how UI Automation clients, mainly assistive technologies, will be interacting with your app in accessibility scenarios.

The **AccScope** tool provides a particularly interesting view of your app because you can see the UI Automation elements either as a visual representation or as a list. If you use the visualization, you can drill down into the parts in a way that you'll be able to correlate with the visual appearance of your app's UI. You can even test the accessibility of your earliest UI prototypes before you've assigned all the logic to the UI, making sure that both the visual interaction and accessibility-scenario navigation for your app is in balance.

One aspect that you can test is whether there are elements appearing in the UI Automation element view that you don't want to appear there. If you find elements you want to omit from the view, or conversely if there are elements missing, you can use the **AutomationProperties.AccessibilityView** XAML attached property to adjust how XAML controls appear in accessibility views. After you've looked at the basic accessibility views, this is also a good opportunity to recheck your tab sequences or spatial navigation as

enabled by arrow keys to make sure users can reach each of the parts that are interactive and exposed in the control view.

Accessibility in the Store

Article • 01/04/2023

Describes the requirements for declaring your Windows app as accessible in the Microsoft Store.

While submitting your app to the Microsoft Store for certification, you can declare your app as accessible. Declaring your app as accessible makes it easier to discover for users who are interested in accessible apps, such as users who have visual impairments. Users discover accessible apps by using the **Accessible** filter while searching the Microsoft Store. Declaring your app as accessible also adds the **Accessible** tag to your app's description.

By declaring your app as accessible, you state that it has the basic accessibility information that users need for primary scenarios using one or more of the following:

- The keyboard.
- A high contrast theme.
- A variable dots per inch (dpi) setting.
- Common assistive technology such as the Windows accessibility features, including Narrator, Magnifier, and On-Screen Keyboard.

You should declare your app as accessible if you built and tested it for accessibility. This means that you did the following:

- Set all the relevant accessibility information for UI elements, including name, role, value, and so on.
- Implemented full keyboard accessibility, enabling the user to:
  - Accomplish primary app scenarios by using only the keyboard.
  - Tab among UI elements in a logical order.
  - Navigate among UI elements within a control by using the arrow keys.
  - Use keyboard shortcuts to reach primary app functionality.
  - Use Narrator touch gestures for Tab and arrow equivalency for devices with no keyboard.
- Ensured that your app UI is visually accessible: has a minimum text contrast ratio of 4.5:1, does not rely on color alone to convey information, and so on.
- Used accessibility testing tools such as **Inspect** and **UIAVerify** to verify your accessibility implementation, and resolved all priority 1 errors reported by such tools.
- Verified your app's primary scenarios from end to end by using Narrator, Magnifier, On-Screen Keyboard, a high contrast theme, and adjusted dpi settings.

See the Accessibility checklist for a review of these procedures and links to resources that will help you accomplish them.

Accessibility checklist

Article • 06/24/2021

Provides a checklist to help you ensure that your Windows app is accessible .

Here we provide a checklist you can use to ensure that your app is accessible.

1. Set the accessible name (required) and description (optional) for content and interactive UI elements in your app.

   An accessible name is a short, descriptive text string that a screen reader uses to announce a UI element. Some UI elements such as **TextBlock** and **TextBox** promote their text content as the default accessible name; see Basic accessibility information.

   You should set the accessible name explicitly for images or other controls that do not promote inner text content as an implicit accessible name. You should use labels for form elements so that the label text can be used as a **LabeledBy** target in the Microsoft UI Automation model for correlating labels and inputs. If you want to provide more UI guidance for users than is typically included in the accessible name, accessible descriptions and tooltips help users understand the UI.

   For more info, see Accessible name and Accessible description.

2. Implement keyboard accessibility:

   - Test the default tab index order for a UI. Adjust the tab index order if necessary, which may require enabling or disabling certain controls, or changing the default values of **TabIndex** on some of the UI elements.
   - Use controls that support arrow-key navigation for composite elements. For default controls, the arrow-key navigation is typically already implemented.
   - Use controls that support keyboard activation. For default controls, particularly those that support the UI Automation **Invoke** pattern, keyboard activation is typically available; check the documentation for that control.
   - Set access keys or implement accelerator keys for specific parts of the UI that support interaction.
   - For any custom controls that you use in your UI, verify that you have implemented these controls with correct **AutomationPeer** support for activation, and defined overrides for key handling as needed to support activation, traversal and access or accelerator keys.

   For more info, see Keyboard interactions.

3. Ensure text is a readable size

    - Windows includes various accessibility tools and settings that users can take advantage of and adjust to their own needs and preferences for reading text. These include:
        - The Magnifier tool, which enlarges a selected area of the UI. You should ensure the layout of text in your app doesn't make it difficult to use Magnifier for reading.
        - Global scale and resolution settings in **Settings->System->Display->Scale and layout**. Exactly which sizing options are available can vary as this depends on the capabilities of the display device.
        - Text size settings in **Settings->Ease of access->Display**. Adjust the **Make text bigger** setting to specify only the size of text in supporting controls across all applications and screens (all UWP text controls support the text scaling experience without any customization or templating).

    > ⓘ **Note**
    >
    > The **Make everything bigger** setting lets a user specify their preferred size for text and apps in general on their primary screen only.

4. Visually verify your UI to ensure that the text contrast is adequate, elements render correctly in the high-contrast themes, and colors are used correctly.

    - Use a color analyzer tool to verify that the visual text contrast ratio is at least 4.5:1.
    - Switch to a high contrast theme and verify that the UI for your app is readable and usable.
    - Ensure that your UI doesn't use color as the only way to convey information.

    For more info, see High-contrast themes and Accessible text requirements.

5. Run accessibility tools, address reported issues, and verify the screen reading experience.

    Use tools such as **Inspect** to verify programmatic access, run diagnostic tools such as **AccChecker** to discover common errors, and verify the screen reading experience with Narrator.

    For more info, see Accessibility testing.

6. Make sure your app manifest settings follow accessibility guidelines.

7. Declare your app as accessible in the Microsoft Store.

   If you implemented the baseline accessibility support, declaring your app as accessible in the Microsoft Store can help reach more customers and get some additional good ratings.

   For more info, see Accessibility in the Store.

Expose basic accessibility information

Article • 01/04/2023

Basic accessibility info is often categorized into name, role, and value. This topic describes code to help your app expose the basic information that assistive technologies need.

Accessible name

An accessible name is a short, descriptive text string that a screen reader uses to announce a UI element. Set the accessible name for UI elements so that have a meaning that is important for understanding the content or interacting with the UI. Such elements typically include images, input fields, buttons, controls, and regions.

This table describes how to define or obtain an accessible name for various types of elements in a XAML UI.

Element type	Description
Static text	For **TextBlock** and **RichTextBlock** elements, an accessible name is automatically determined from the visible (inner) text. All of the text in that element is used as the name. See Name from inner text.
Images	The XAML **Image** element does not have a direct analog to the HTML **alt** attribute of **img** and similar elements. Either use **AutomationProperties.Name** to provide a name, or use the captioning technique. See Accessible names for images.
Form elements	The accessible name for a form element should be the same as the label that is displayed for that element. See Labels and LabeledBy.
Buttons and links	By default, the accessible name of a button or link is based on the visible text, using the same rules as described in Name from inner text. In cases where a button contains only an image, use **AutomationProperties.Name** to provide a text-only equivalent of the button's intended action.

Most container elements such as panels do not promote their content as accessible name. This is because it is the item content that should report a name and corresponding role, not its container. The container element might report that it is an element that has children in a Microsoft UI Automation representation, such that the assistive technology logic can traverse it. But users of assistive technologies don't generally need to know about the containers and thus most containers aren't named.

Role and value

The controls and other UI elements that are part of the XAML vocabulary implement UI Automation support for reporting role and value as part of their definitions. You can use UI Automation tools to examine the role and value information for the controls, or you can read the documentation for the AutomationPeer implementations of each control. The available roles in a UI Automation framework are defined in the AutomationControlType enumeration. UI Automation clients such as assistive technologies can obtain role information by calling methods that the UI Automation framework exposes by using the control's **AutomationPeer**.

Not all controls have a value. Controls that do have a value report this information to UI Automation through the peers and patterns that are supported by that control. For example, a TextBox form element does have a value. An assistive technology can be a UI Automation client and can discover both that a value exists and what the value is. In this specific case the **TextBox** supports the IValueProvider pattern through the TextBoxAutomationPeer definitions.

> ⓘ Note
>
> For cases where you use **AutomationProperties.Name** or other techniques to supply the accessible name explicitly, do not include the same text as is used by the control role or type information in the accessible name. For example do not include strings such as "button" or "list" in the name. The role and type information comes from a different UI Automation property (**LocalizedControlType**) that is supplied by the default control support for UI Automation. Many assistive technologies append the **LocalizedControlType** to the accessible name, so duplicating the role in the accessible name can result in unnecessarily repeated words. For example, if you give a **Button** control an accessible name of "button" or include "button" as the last part of the name, this might be read by screen readers as "button button". You should test this aspect of your accessibility info using Narrator.

Influencing the UI Automation tree views

The UI Automation framework has a concept of tree views, where UI Automation clients can retrieve the relationships between elements in a UI using three possible views: raw, control, and content. The control view is the view that's often used by UI Automation clients because it provides a good representation and organization of the elements in a UI that are interactive. Testing tools usually enable you to choose which tree view to use when the tool presents the organization of elements.

By default, any Control derived class and a few other elements will appear in the control view when the UI Automation framework represents the UI for a Windows app. But sometimes you don't want an element to appear in the control view because of UI composition, where that element is duplicating information or presenting information that's unimportant for accessibility scenarios. Use the attached property AutomationProperties.AccessibilityView to change how elements are exposed to the tree views. If you put an element in the **Raw** tree, most assistive technologies won't report that element as part of their views. To see some examples of how this works in existing controls, open the generic.xaml design reference XAML file in a text editor, and search for **AutomationProperties.AccessibilityView** in the templates.

Name from inner text

To make it easier to use strings that already exist in the visible UI for accessible name values, many of the controls and other UI elements provide support for automatically determining a default accessible name based on inner text within the element, or from string values of content properties.

- TextBlock, RichTextBlock, TextBox and **RichTextBlock** each promote the value of the **Text** property as the default accessible name.
- Any ContentControl subclass uses an iterative "ToString" technique to find strings in its Content value, and promotes these strings as the default accessible name.

> ⓘ **Note**
>
> As enforced by UI Automation, the accessible name length cannot be greater than 2048 characters. If a string used for automatic accessible name determination exceeds that limit, the accessible name is truncated at that point.

Accessible names for images

To support screen readers and to provide the basic identifying information for each element in the UI, you sometimes must provide text alternatives to non-textual information such as images and charts (excluding any purely decorative or structural elements). These elements don't have inner text so the accessible name won't have a calculated value. You can set the accessible name directly by setting the AutomationProperties.Name attached property as shown in this example.

XAML

XML

```
<!-- Comment -->
<Image Source="product.png"
  AutomationProperties.Name="An image of a customer using the product."/>
```

Alternatively, consider including a text caption that appears in the visible UI and that also serves as the label-associated accessibility information for the image content. Here's an example:

XAML

XML

```
<Image HorizontalAlignment="Left" Width="480" x:Name="img_MyPix"
  Source="snoqualmie-NF.jpg"
  AutomationProperties.LabeledBy="{Binding ElementName=caption_MyPix}"/>
<TextBlock x:Name="caption_MyPix">Mount Snoqualmie Skiing</TextBlock>
```

Labels and LabeledBy

The preferred way to associate a label with a form element is to use a **TextBlock** with an **x:Name** for label text, and then to set the **AutomationProperties.LabeledBy** attached property on the form element to reference the labeling **TextBlock** by its XAML name. If you use this pattern, assistive technologies can use the label text as the accessible name for the form field. Here's an example that shows this technique.

XAML

XML

```
<StackPanel x:Name="LayoutRoot" Background="White">
   <StackPanel Orientation="Horizontal">
     <TextBlock Name="lbl_FirstName">First name</TextBlock>
     <TextBox
      AutomationProperties.LabeledBy="{Binding ElementName=lbl_FirstName}"
      Name="tbFirstName" Width="100"/>
   </StackPanel>
   <StackPanel Orientation="Horizontal">
     <TextBlock Name="lbl_LastName">Last name</TextBlock>
     <TextBox
      AutomationProperties.LabeledBy="{Binding ElementName=lbl_LastName}"
      Name="tbLastName" Width="100"/>
   </StackPanel>
 </StackPanel>
```

Accessible description (optional)

An accessible description provides additional accessibility information about a particular UI element. You typically provide an accessible description when an accessible name alone does not adequately convey an element's purpose.

The Narrator screen reader reads an element's accessible description only when the user requests more information about the element by pressing CapsLock+F.

The accessible name is meant to identify the control rather than to fully document its behavior. If a brief description is not enough to explain the control, you can set the **AutomationProperties.HelpText** attached property in addition to **AutomationProperties.Name**.

Testing accessibility early and often

Ultimately, the best approach for supporting screen readers is to test your app using a screen reader yourself. That will show you how the screen reader behaves and what basic accessibility information might be missing from the app. Then you can adjust the UI or UI Automation property values accordingly. For more info, see Accessibility testing.

One of the tools you can use for testing accessibility is called **AccScope**. The **AccScope** tool is particularly useful because you can see visual representations of your UI that represent how assistive technologies might view your app as an automation tree. In particular, there's a Narrator mode that gives a view of how Narrator gets text from your app and how it organizes the elements in the UI. AccScope is designed so that it can be used and be useful throughout a development cycle for an app, even during the preliminary design phase. For more info see AccScope.

Accessible names from dynamic data

Windows supports many controls that can be used to display values that come from an associated data source, through a feature known as *data binding*. When you populate lists with data items, you may need to use a technique that sets accessible names for data-bound list items after the initial list is populated. For more info, see "Scenario 4" in the XAML accessibility sample.

Accessible names and localization

To make sure that the accessible name is also an element that is localized, you should use correct techniques for storing localizable strings as resources and then referencing

the resource connections with x:Uid directive values. If the accessible name is coming from an explicitly set **AutomationProperties.Name** usage, make sure that the string there is also localizable.

Note that attached properties such as the **AutomationProperties** properties use a special qualifying syntax for the resource name, so that the resource references the attached property as applied to a specific element. For example, the resource name for **AutomationProperties.Name** as applied to a UI element named `MediumButton` is: `MediumButton.[using:Windows.UI.Xaml.Automation]AutomationProperties.Name`.

Keyboard accessibility

Article • 06/11/2024

Building keyboard accessibility (for traditional, modified, or keyboard emulation hardware) into your app, provides users who are blind, have low vision, motor disabilities, or have little or no use of their hands, the ability to navigate through and use the full functionality of your app. In addition, users without disabilities might choose the keyboard for navigation due to preference or efficiency.

If your app does not provide good keyboard access, users who are blind or have mobility issues might have difficulty using your app.

Keyboard navigation among UI elements

To interact with a control using the keyboard, the control must have focus. To receive focus (without using a pointer), the control must be accessible through tab navigation. By default, the tab order of controls is the same as the order in which they are added to a design surface, declared in XAML, or programmatically added to a container.

Typically, the default tab order is based on how controls are defined in XAML, particularly as that is the order in which the controls are traversed by screen readers. However, the default order does not necessarily correspond to the visual order. The actual display position might depend on the parent layout container and various properties of child elements that can affect the layout.

To ensure your app has an optimal tab order, test the behavior yourself. If you use a grid or table for your layout, the order in which users might read the screen versus the tab order could be very different. This isn't always a problem, but just make sure to test your app's functionality through both touch and keyboard to verify that your UI is optimized for both input methods.

You can make the tab order match the visual order by either adjusting the XAML or overriding the default tab order. THe following example shows how to use the **TabIndex** property with a **Grid** layout that uses column-first tab navigation.

XAML

```
<Grid>
  <Grid.RowDefinitions>...</Grid.RowDefinitions>
  <Grid.ColumnDefinitions>...</Grid.ColumnDefinitions>

  <TextBlock Grid.Column="1" HorizontalAlignment="Center">Groom</TextBlock>
  <TextBlock Grid.Column="2" HorizontalAlignment="Center">Bride</TextBlock>
```

```
  <TextBlock Grid.Row="1">First name</TextBlock>
  <TextBox x:Name="GroomFirstName" Grid.Row="1" Grid.Column="1"
TabIndex="1"/>
  <TextBox x:Name="BrideFirstName" Grid.Row="1" Grid.Column="2"
TabIndex="3"/>

  <TextBlock Grid.Row="2">Last name</TextBlock>
  <TextBox x:Name="GroomLastName" Grid.Row="2" Grid.Column="1"
TabIndex="2"/>
  <TextBox x:Name="BrideLastName" Grid.Row="2" Grid.Column="2"
TabIndex="4"/>
</Grid>
```

In some cases, you might want to exclude a specific control from the tab order. This is typically accomplished by making the control noninteractive by setting its **IsEnabled** property to **false**. A disabled control is automatically excluded from the tab order.

If you want to exclude an interactive control from the tab order, you can set the **IsTabStop** property to **false**.

By default, UI elements that support focus are typically included in the tab order. Some exceptions to this include certain text-display types (such as **RichTextBlock**) that support focus for text selection and clipboard access but are not in the tab order because they are static text elements. These controls are not conventionally interactive (they can't be invoked, and don't require text input, but do support the Text control pattern that supports finding and adjusting selection points in text). Text controls will still be detected by assistive technologies, and read aloud in screen readers, but that relies on techniques other than tab order.

Whether you adjust **TabIndex** values or use the default order, these rules apply:

- If **TabIndex** is not set on an element, the default value is Int32.MaxValue and the tab order is based on declaration order in the XAML or child collections.
- If **TabIndex** is set on an element:
  - UI elements with **TabIndex** equal to 0 are added to the tab order based on declaration order in XAML or child collections.
  - UI elements with **TabIndex** greater than 0 are added to the tab order based on the **TabIndex** value.
  - UI elements with **TabIndex** less than 0 are added to the tab order and appear before any zero value.

The following code snippet shows a collection of elements with various **TabIndex** settings (`B` is assigned the value of Int32.MaxValue, or 2,147,483,647).

XAML

```
<StackPanel Background="#333">
  <StackPanel Background="#FF33FF">
    <Button>A</Button>
    <Button TabIndex="2147483647">B</Button>
    <Button>C</Button>
  </StackPanel>
  <StackPanel Background="#33FFFF">
    <Button TabIndex="1">D</Button>
    <Button TabIndex="1">E</Button>
    <Button TabIndex="0">F</Button>
  </StackPanel>
</StackPanel>
```

This results in the following tab order:

1. F
2. D
3. E
4. A
5. B
6. C

Keyboard navigation between application panes with F6

An application pane is a logical area of prominent, related UI within an application window (for example, Microsoft Edge panes include the address bar, the bookmark bar, the tab bar, and the content panel). The F6 key can be used to navigate between these panes, where groups of child elements can then be accessed using standard keyboard navigation.

While keyboard navigation can provide an accessibly-compliant UI, making an accessibly-*usable* UI often require a few more steps. Typically, this includes:

- Listening to **F6** to navigate between important sections of your UI.
- Adding **keyboard shortcuts** for common actions in your UI.
- Adding **access keys** to important controls in your UI.

See Keyboard shortcuts below and Access keys for more guidance about implementing shortcuts and access keys.

Optimize for F6

F6 lets keyboard users efficiently navigate between panes of UI without tabbing through potentially hundreds of controls.

For example, F6 in Microsoft Edge cycles between the address bar, the bookmark bar, the tab bar, and the content panel. As a web page can potentially have hundreds of tabable controls, F6 can make it easier for keyboard users to reach the tab bar and address bar without using application-specific shortcuts.

The F6 tab cycle can also loosely correspond to landmarks or headings in content, though it doesn't need to match exactly. F6 should focus on large, distinct regions in your UI, whereas landmarks can be more granular. For example, you might mark an app bar and its search box as landmarks, but only include the app bar itself in the F6 cycle.

> **ⓘ Important**
>
> You must implement F6 navigation in your app as it is not supported natively.

Where possible, regions in the F6 cycle should have an accessible name: either through a landmark or by manually adding an **AutomationProperties.Name** to the "root" element of the region.

Shift-F6 should cycle in the opposite direction.

Keyboard navigation within a UI element

For composite controls, it is important to ensure proper inner navigation among the contained elements. A composite control can manage the currently active child element to reduce the overhead of having all child elements support focus. The composite control is included in the tab order and handles keyboard navigation events itself. Many composite controls already have some inner navigation logic built into their event handling. For example, arrow-key traversal of items is enabled by default on the **ListView**, **GridView**, **ListBox** and **FlipView** controls.

Keyboard alternatives to pointer actions and events for specific control elements

UI elements that can be clicked should also be invokable through the keyboard. To use the keyboard with a UI element, the element must have focus (only classes that derive from **Control** support focus and tab navigation).

For UI elements that can be invoked, implement keyboard event handlers for the Spacebar and Enter keys. This ensures basic keyboard accessibility support and lets

users reach all interactive UI elements and activate functionality by using the keyboard only.

Where an element does not support focus, you can create your own custom control. In this case, to enable focus, you must set the **IsTabStop** property to **true** and you must provide a visual indication of the focused visual state with a focus indicator.

However, it can be easier to use control composition so that the support for tab stops, focus, and Microsoft UI Automation peers and patterns are handled by the control within which you choose to compose your content. For example, instead of handling a pointer-pressed event on an **Image**, wrap that element in a **Button** to get pointer, keyboard, and focus support.

XAML

```
<!--Don't do this.-->
<Image Source="sample.jpg" PointerPressed="Image_PointerPressed"/>

<!--Do this instead.-->
<Button Click="Button_Click"><Image Source="sample.jpg"/></Button>
```

Keyboard shortcuts

In addition to implementing keyboard navigation and activation, it is also good practice to implement keyboard shortcuts such as keyboard accelerators and access keys for important or frequently used functionality.

A *shortcut* is a keyboard combination that provides an efficient way for the user to access app functionality. There are two kinds of shortcut:

- *Accelerators* are shortcuts that invoke an app command. Your app may or may not provide specific UI that corresponds to the command. Accelerators typically consist of the Ctrl key plus a letter key.
- *Access keys* are shortcuts that set focus to specific UI in your application. Access keys typicaly consist of the Alt key plus a letter key.

Always provide an easy way for users who rely on screen readers and other assistive technology to discover your app's shortcut keys. Communicate shortcut keys by using tooltips, accessible names, accessible descriptions, or some other form of on-screen communication. At a minimum, shortcut keys should be well documented in your app's Help content.

You can document access keys through screen readers by setting the AutomationProperties.AccessKey attached property to a string that describes the shortcut key. There is also an AutomationProperties.AcceleratorKey attached property for documenting non-mnemonic shortcut keys, although screen readers generally treat both properties the same way. Try to document shortcut keys in multiple ways, using tooltips, automation properties, and written Help documentation.

The following example demonstrates how to document shortcut keys for media play, pause, and stop buttons.

XAML

```
<Grid KeyDown="Grid_KeyDown">

  <Grid.RowDefinitions>
    <RowDefinition Height="Auto" />
    <RowDefinition Height="Auto" />
  </Grid.RowDefinitions>

  <MediaElement x:Name="DemoMovie" Source="xbox.wmv"
    Width="500" Height="500" Margin="20" HorizontalAlignment="Center" />

  <StackPanel Grid.Row="1" Margin="10"
    Orientation="Horizontal" HorizontalAlignment="Center">

    <Button x:Name="PlayButton" Click="MediaButton_Click"
      ToolTipService.ToolTip="Shortcut key: Ctrl+P"
      AutomationProperties.AcceleratorKey="Control P">
      <TextBlock>Play</TextBlock>
    </Button>

    <Button x:Name="PauseButton" Click="MediaButton_Click"
      ToolTipService.ToolTip="Shortcut key: Ctrl+A"
      AutomationProperties.AcceleratorKey="Control A">
      <TextBlock>Pause</TextBlock>
    </Button>

    <Button x:Name="StopButton" Click="MediaButton_Click"
      ToolTipService.ToolTip="Shortcut key: Ctrl+S"
      AutomationProperties.AcceleratorKey="Control S">
      <TextBlock>Stop</TextBlock>
    </Button>
  </StackPanel>
</Grid>
```

ⓘ Important

Setting the AutomationProperties.AcceleratorKey or AutomationProperties.AccessKey doesn't enable keyboard functionality. This only

indicates what keys should be used to the UI Automation framework and then can be passed on to users via assistive technologies.

Key handling is implemented in code-behind, not XAML. You still need to attach handlers for **KeyDown** or **KeyUp** events on the relevant control in order to actually implement the keyboard shortcut behavior in your app. Also, the underline text decoration for an access key is not provided automatically. You must explicitly underline the text for the specific key in your mnemonic as inline **Underline** formatting if you wish to show underlined text in the UI.

For simplicity, the preceding example omits the use of resources for strings such as "Ctrl+A". However, you must also consider shortcut keys during localization. Localizing shortcut keys is relevant because the choice of key to use as the shortcut key typically depends on the visible text label for the element.

For more guidance about implementing shortcut keys, see Shortcut keys in the Windows User Experience Interaction Guidelines.

Implementing a key event handler

Input events (such as the key events) use an event concept called *routed events*. A routed event can bubble up through the child elements of a parent composite control, such that the parent control can handle events for multiple child elements. This event model is convenient for defining shortcut key actions for a control that contains several child elements, none of which can have focus or be part of the tab order.

For example code that shows how to write a key event handler that includes checking for modifiers such as the Ctrl key, see Keyboard interactions.

Keyboard navigation for custom controls

We recommend using the arrow keys as keyboard shortcuts for navigating among child elements in cases where the child elements have a spacial relationship to each other. If tree-view nodes have separate sub-elements for handling expand-collapse and node activation, use the left and right arrow keys to provide keyboard expand-collapse functionality. If you have an oriented control that supports directional traversal within the control content, use the appropriate arrow keys.

Generally you implement custom key handling for custom controls by including an override of the **OnKeyDown** and **OnKeyUp** methods as part of the class logic.

An example of a visual state for a focus indicator

As mentioned earlier, any custom control that supports focus should have a visual focus indicator. Typically, that focus indicator is just a rectangle outlining the bounding rectangle of the control. The **Rectangle** for visual focus is a peer element to the rest of the control's composition in a control template, but is initially set with a **Visibility** value of **Collapsed** because the control isn't focused yet. When the control does get focus, a visual state is invoked that specifically sets the **Visibility** of the focus visual to **Visible**. Once focus is moved elsewhere, another visual state is called, and the **Visibility** becomes **Collapsed**.

All focusable XAML controls display an appropriate visual focus indicator when focused. The user's selected them can also affect the indicator appearance (particularly if the user is using a high contrast mode). If you're using the XAML controls in your UI (and are not replacing the control templates), you don't need to do anything extra to get default visual focus indicators. However, if you intend to retemplate a control, or if you're curious about how XAML controls provide their visual focus indicators, the remainder of this section explains how this is done in XAML and the control logic.

Here's some example XAML that comes from the default XAML template for a **Button**.

XAML

XML

```
<ControlTemplate TargetType="Button">
...
    <Rectangle
      x:Name="FocusVisualWhite"
      IsHitTestVisible="False"
      Stroke="{ThemeResource FocusVisualWhiteStrokeThemeBrush}"
      StrokeEndLineCap="Square"
      StrokeDashArray="1,1"
      Opacity="0"
      StrokeDashOffset="1.5"/>
    <Rectangle
      x:Name="FocusVisualBlack"
      IsHitTestVisible="False"
      Stroke="{ThemeResource FocusVisualBlackStrokeThemeBrush}"
      StrokeEndLineCap="Square"
      StrokeDashArray="1,1"
      Opacity="0"
      StrokeDashOffset="0.5"/>
...
</ControlTemplate>
```

So far this is just the composition. To control the focus indicator's visibility, you define visual states that toggle the **Visibility** property. This is done using the VisualStateManager and the VisualStateManager.VisualStateGroups attached property, as applied to the root element that defines the composition.

XAML

```
<ControlTemplate TargetType="Button">
  <Grid>
    <VisualStateManager.VisualStateGroups>
       <!--other visual state groups here-->
       <VisualStateGroup x:Name="FocusStates">
         <VisualState x:Name="Focused">
           <Storyboard>
             <DoubleAnimation
               Storyboard.TargetName="FocusVisualWhite"
               Storyboard.TargetProperty="Opacity"
               To="1" Duration="0"/>
             <DoubleAnimation
               Storyboard.TargetName="FocusVisualBlack"
               Storyboard.TargetProperty="Opacity"
               To="1" Duration="0"/>
         </VisualState>
         <VisualState x:Name="Unfocused" />
         <VisualState x:Name="PointerFocused" />
       </VisualStateGroup>
     <VisualStateManager.VisualStateGroups>
<!--composition is here-->
   </Grid>
</ControlTemplate>
```

Note how only one of the named states adjusts **Visibility** directly whereas the others are apparently empty. With visual states, as soon as the control uses another state from the same **VisualStateGroup**, any animations applied by the previous state are immediately canceled. Because the default **Visibility** from composition is **Collapsed**, the rectangle will not appear. The control logic controls this by listening for focus events like **GotFocus** and changing the states with **GoToState**. Often this is already handled for you if you are using a default control or customizing based on a control that already has that behavior.

Keyboard accessibility and devices without a hardware keyboard

Some devices don't have a dedicated, hardware keyboard and rely on a Soft Input Panel (SIP) instead. Screen readers can read text input from the **Text** SIP and users can discover where their fingers are because the screen reader can detect that the user is scanning keys, and reads the scanned key name aloud. Also, some of the keyboard-

oriented accessibility concepts can be mapped to related assistive technology behaviors that don't use a keyboard at all. For example, even though a SIP won't include a Tab key, Narrator supports a touch gesture that's the equivalent of pressing the Tab key, so having a useful tab order through the controls in a UI is still crtical for accessibility. Narrator also supports many other touch gestures, including arrow keys for navigating within complex controls (see Narrator keyboard commands and touch gestures).

Examples

Open the WinUI 3 Gallery app and see keyboard accessibility support in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Screen readers and hardware system buttons

Article • 06/24/2021

Screen-readers, such as Narrator, must be able to recognize and handle hardware system button events and communicate their state to users. In some cases, the screen reader might need to handle these hardware button events exclusively and not let them bubble up to other handlers.

Beginning with Windows 10 version 2004, UWP applications can listen for and handle the **Fn** hardware system button events in the same way as other hardware buttons. Previously, this system button acted only as a modifier for how other hardware buttons reported their events and state.

> **Note**
>
> Fn button support is OEM-specific and can include features such as the ability to toggle/lock on or off (vs. a press-and-hold key combination), along with a corresponding lock indicator light (which might not be helpful to users who are blind or have a vision impairment).

Fn button events are exposed through a new SystemButtonEventController Class in the Windows.UI.Input namespace. The SystemButtonEventController object supports the following events:

- SystemFunctionButtonPressed
- SystemFunctionButtonReleased
- SystemFunctionLockChanged
- SystemFunctionLockIndicatorChanged

> **Important**
>
> The SystemButtonEventController cannot receive these events if they have already been handled by a higher priority handler.

Examples

In the following examples, we show how to create a SystemButtonEventController based on a DispatcherQueue and handle the four events supported by this object.

It is common for more than one of the supported events to fire when the Fn button is pressed. For example, pressing the Fn button on a Surface keyboard fires SystemFunctionButtonPressed, SystemFunctionLockChanged, and SystemFunctionLockIndicatorChanged at the same time.

1. In this first snippet, we simply include the required namespaces and specify some global objects, including the DispatcherQueue and the DispatcherQueueController objects for managing the SystemButtonEventController thread.

   We then specify the event tokens returned when registering the SystemButtonEventController event-handling delegates.

   C++/WinRT

   ```
   namespace winrt
   {
       using namespace Windows::System;
       using namespace Windows::UI::Input;
   }

   ...

   // Declare related members
   winrt::DispatcherQueueController _queueController;
   winrt::DispatcherQueue _queue;
   winrt::SystemButtonEventController _controller;
   winrt::event_token _fnKeyDownToken;
   winrt::event_token _fnKeyUpToken;
   winrt::event_token _fnLockToken;
   ```

2. We also specify an event token for the SystemFunctionLockIndicatorChanged event along with a bool to indicate whether the application is in "Learning Mode" (where the user is simply trying to explore the keyboard without performing any functions).

   C++/WinRT

   ```
   winrt::event_token _fnLockIndicatorToken;
   bool _isLearningMode = false;
   ```

3. This third snippet includes the corresponding event handler delegates for each event supported by the SystemButtonEventController object.

Each event handler announces the event that has occurred. In addition, the FunctionLockIndicatorChanged handler also controls whether the app is in "Learning" mode (`_isLearningMode` = true), which prevents the event from bubbling to other handlers and lets the user explore keyboard features without actually performing the action.

C++/WinRT

```
void SetupSystemButtonEventController()
{
    // Create dispatcher queue controller and dispatcher queue
    _queueController =
winrt::DispatcherQueueController::CreateOnDedicatedThread();
    _queue = _queueController.DispatcherQueue();

    // Create controller based on new created dispatcher queue
    _controller =
winrt::SystemButtonEventController::CreateForDispatcherQueue(_queue);

    // Add Event Handler for each different event
    _fnKeyDownToken = _controller->FunctionButtonPressed(
        [](const winrt::SystemButtonEventController& /*sender*/, const
winrt:: FunctionButtonEventArgs& args)
        {
            // Mock function to read the sentence "Fn button is
pressed"
            PronounceFunctionButtonPressedMock();
            // Set Handled as true means this event is consumed by this
controller
            // no more targets will receive this event
            args.Handled(true);
        });

        _fnKeyUpToken = _controller->FunctionButtonReleased(
            [](const winrt::SystemButtonEventController& /*sender*/,
const winrt:: FunctionButtonEventArgs& args)
            {
                // Mock function to read the sentence "Fn button is up"
                PronounceFunctionButtonReleasedMock();
                // Set Handled as true means this event is consumed by
this controller
                // no more targets will receive this event
                args.Handled(true);
            });

    _fnLockToken = _controller->FunctionLockChanged(
        [](const winrt::SystemButtonEventController& /*sender*/, const
winrt:: FunctionLockChangedEventArgs& args)
        {
            // Mock function to read the sentence "Fn shift is
locked/unlocked"
            PronounceFunctionLockMock(args.IsLocked());
```

```
            // Set Handled as true means this event is consumed by this
controller
            // no more targets will receive this event
            args.Handled(true);
        });

    _fnLockIndicatorToken = _controller->FunctionLockIndicatorChanged(
        [](const winrt::SystemButtonEventController& /*sender*/, const
winrt:: FunctionLockIndicatorChangedEventArgs& args)
        {
            // Mock function to read the sentence "Fn lock indicator is
on/off"
            PronounceFunctionLockIndicatorMock(args.IsIndicatorOn());
            // In learning mode, the user is exploring the keyboard.
They expect the program
            // to announce what the key they just pressed WOULD HAVE
DONE, without actually
            // doing it. Therefore, handle the event when in learning
mode so the key is ignored
            // by the system.
            args.Handled(_isLearningMode);
        });
}
```

Landmarks and Headings

Article • 06/11/2024

Landmarks and **headings** help users of assistive technology (AT) navigate a UI more efficiently by uniquely identifying different sections of a user interface.

Overview

A user interface is typically organized in a visually efficient way, allowing a sighted user to quickly skim for what interests them without having to slow down to read *all* the content. A screen reader user needs to have this same skimming ability. Marking content as landmarks and headings provides the user of a screen reader the option to skim content similar to the way a sighted user would.

The concepts of ARIA landmarks, ARIA headings, and HTML headings have been used in web content for years to allow faster navigation by screen reader users. Web pages utilize landmarks and headings to make their content more usable by allowing the AT user to quickly get to the large chunk (landmark) and smaller chunk (heading).

Specifically, screen readers have commands allowing users to jump between landmarks and jump between headings (next/previous or specific heading level).

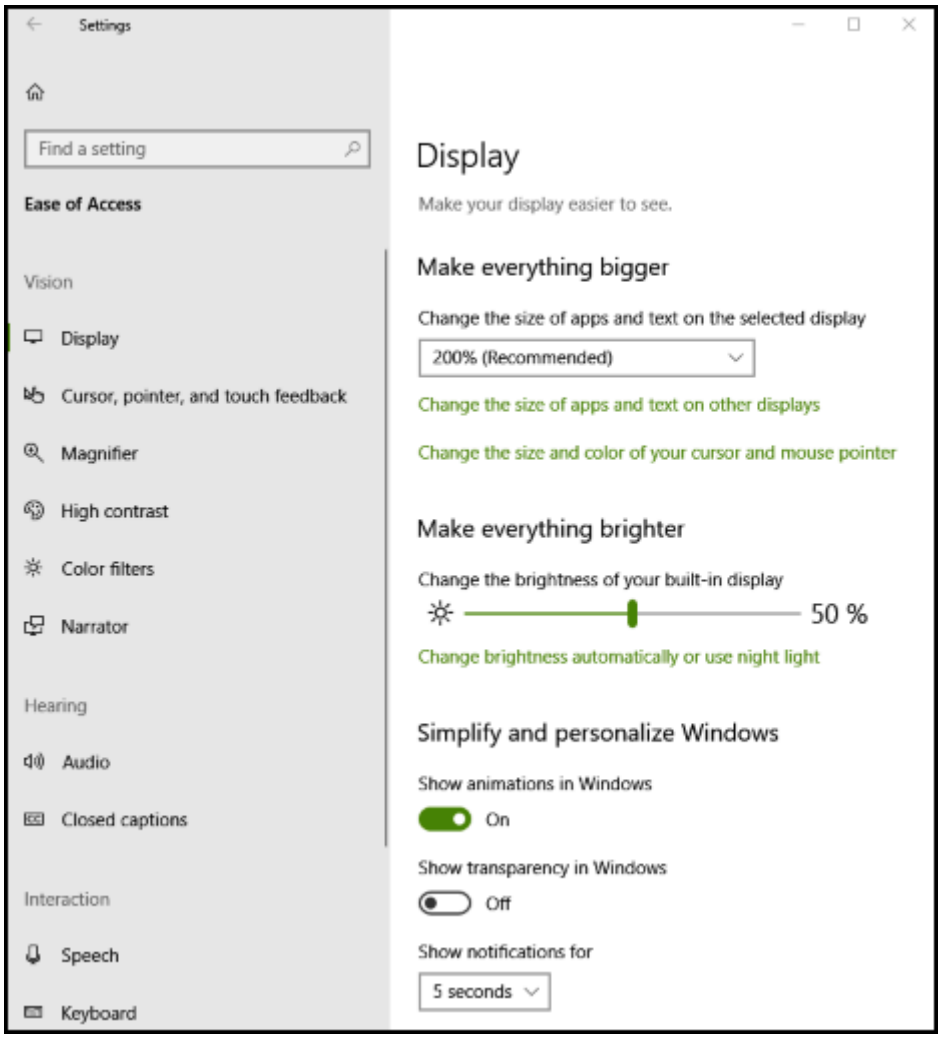
Landmarks enable content to be grouped into various categories such as *search*, *navigation*, *main content*, and so on. Once grouped, the AT user can quickly navigate between the groups. This quick navigation allows the user to skip potentially substantial amounts of content that previously required navigation item by item.

For example, when using a tab panel, consider making it a *navigation* landmark. When using a search edit box, consider making it a *search* landmark, and consider setting your main content as a *main content* landmark.

Whether within a landmark or even outside a landmark, consider annotating sub-elements as headings with logical heading levels.

The Windows Settings app

The following image shows the **Ease of Access** page in a previous version of the Windows Settings app.



For this page, the search edit box is wrapped within a search landmark, the navigation elements on the left are wrapped within a navigation landmark, and the main content on the right is wrapped within a main content landmark.

Within the navigation landmark there is a main group heading called **Ease of Access** (heading level 1) with sub-options of **Vision**, **Hearing**, and so on (heading level 2). Within the main content, **Display** is set to heading level 1 with sub-groups such as **Make everything bigger** set to heading level 2.

The Settings app would be accessible without landmarks and headings, but it becomes much more usable with them. In this case, a user with a screen reader can quickly get to the group (landmark) they're interested in, and from there they can then quickly get to the sub-group (heading).

Usage

Use AutomationProperties.LandmarkTypeProperty to identify the type of landmark for a UI element. This landmark UI element would then encapsulate all the other UI elements relevant to that landmark.

Use AutomationProperties.LocalizedLandmarkTypeProperty to name the landmark. If you select a predefined landmark type, such as main or navigation, these names will be used for the landmark name. However, if you set the landmark type to custom, you must name the landmark through this property (you can also use this property to override the default names from the pre-defined landmark types).

Use AutomationProperties.HeadingLevel to set the UI element as a heading of a specific level from *Level1* through *Level9*.

Use the F6 key and handler to support navigation between landmarks, which is a common pattern in complex apps like File Explorer and Outlook. See Keyboard navigation between application panes with F6 for more guidance.

Examples

See the Code samples for resolving common programmatic accessibility issues in Windows desktop apps to resolve many common programmatic accessibility issues in Windows desktop apps.

These code samples are referenced directly by Microsoft Accessibility Insights for Windows, which can help to identify accessibility issues in your app UI.

Contrast themes

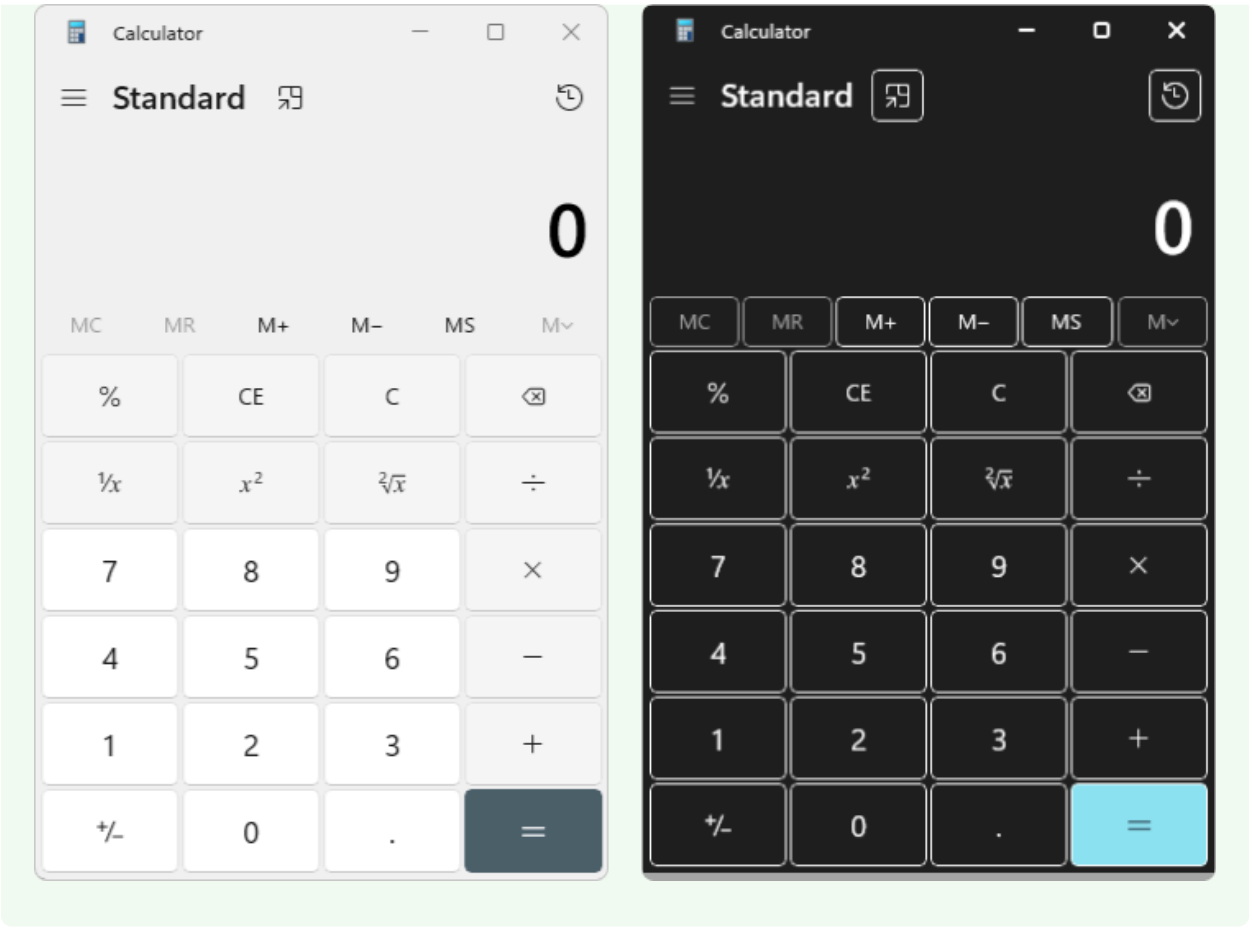
Article • 02/27/2025

Contrast themes use a small palette of colors (with a contrast ratio of at least 7:1) to help make elements in the UI easier to see, reduce eye strain, improve text readability, and accommodate user preferences.

> **Note**
>
> Don't confuse contrast themes with light and dark themes, which support a much larger color palette and don't necessarily increase contrast or make things easier to see. For more on light and dark themes, see Color.

To see how your app behaves with contrast themes, enable and customize them through the *Settings* > *Accessibility* > *Contrast themes* page.

> **Tip**
>
> You can also press the left-Alt key + Shift key + Print screen (PrtScn on some keyboards) to quickly turn contrast themes on or off. If you have not selected a theme previously, the Aquatic theme is used by default (shown in the following image).



Setting HighContrastAdjustment to None

Windows apps have HighContrastAdjustment turned on by default. This sets all text color to white with a solid black highlight behind it, ensuring sufficient contrast against all backgrounds. If you are using brushes correctly, this setting should be turned off.

Detecting high contrast

You can programmatically check if the current theme is a contrast theme through the AccessibilitySettings class (you must call the **AccessibilitySettings** constructor from a scope where the app is initialized and is already displaying content).

Creating theme dictionaries

A ResourceDictionary.ThemeDictionaries object can indicate theme colors that are different from the system-defined colors by specifying brushes for the **Default** (Dark), **Light**, and **HighContrast** contrast themes.

> **Tip**

Contrast theme refers to the feature in general, while **HighContrast** refers to the specific dictionary being referenced.

1. In App.xaml, create a **ThemeDictionaries** collection with both a **Default** and a **HighContrast** ResourceDictionary (a **Light** ResourceDictionary is not necessary for this example).

2. In the **Default** dictionary, create the type of Brush you need (usually a **SolidColorBrush**). Give it an *x:Key* name corresponding to its intended use (a **StaticResource** referencing an existing system brush would also be appropriate).

3. In the **HighContrast** ResourceDictionary (shown in the following code snippet), specify an appropriate **SystemColor** brush. See Contrast colors for details on picking one of the dynamic system **HighContrast** colors for the **SystemColor** brush.

XAML

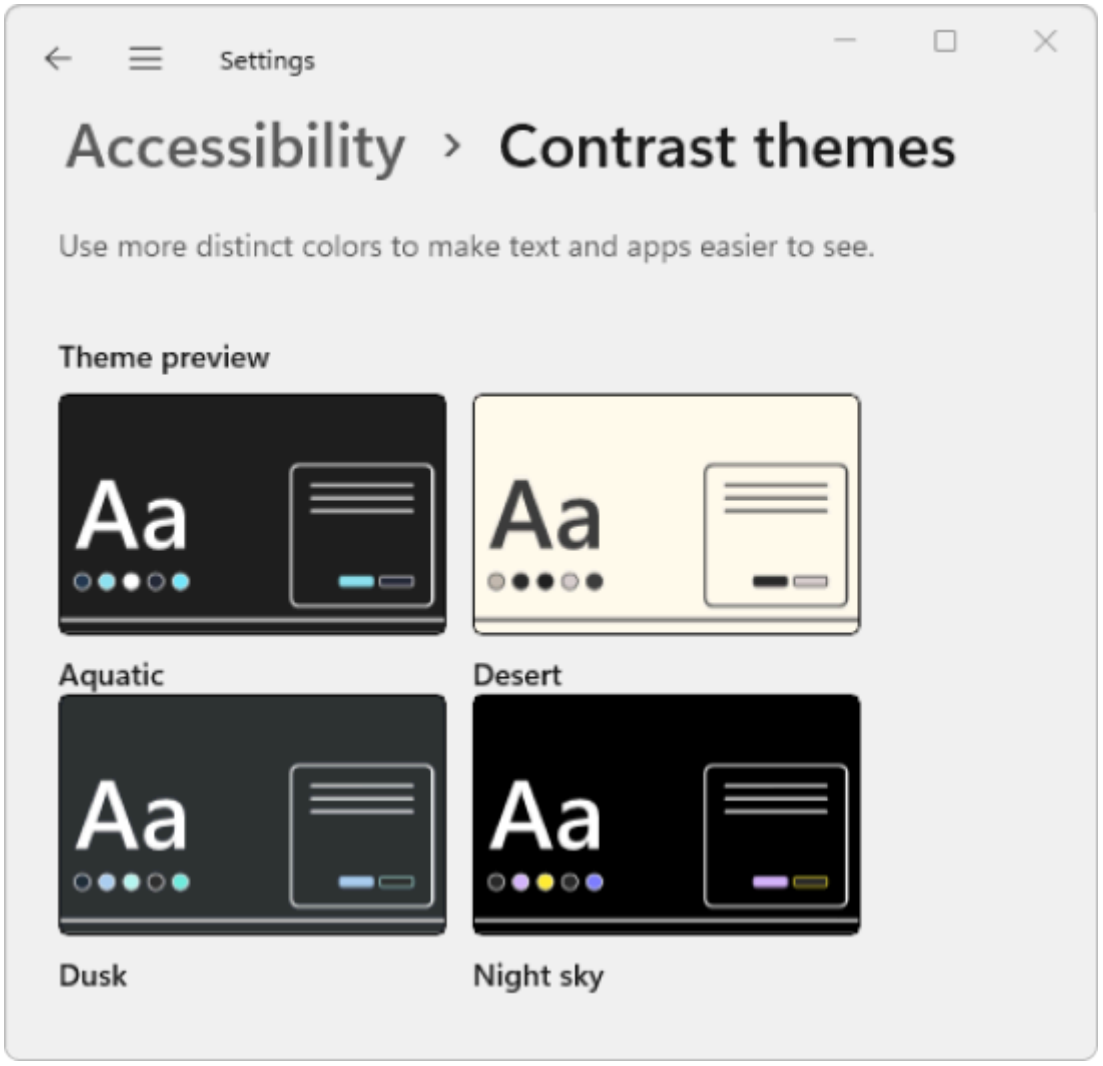
```
<Application.Resources>
    <ResourceDictionary>
        <ResourceDictionary.ThemeDictionaries>
            <!-- Default is a fallback if a more precise theme isn't
called
            out below -->
            <ResourceDictionary x:Key="Default">
                <SolidColorBrush x:Key="BrandedPageBackgroundBrush"
Color="#E6E6E6" />
            </ResourceDictionary>

            <!-- Optional, Light is used in light theme.
            If included, Default will be used for Dark theme -->
            <ResourceDictionary x:Key="Light">
                <SolidColorBrush x:Key="BrandedPageBackgroundBrush"
Color="#E6E6E6" />
            </ResourceDictionary>

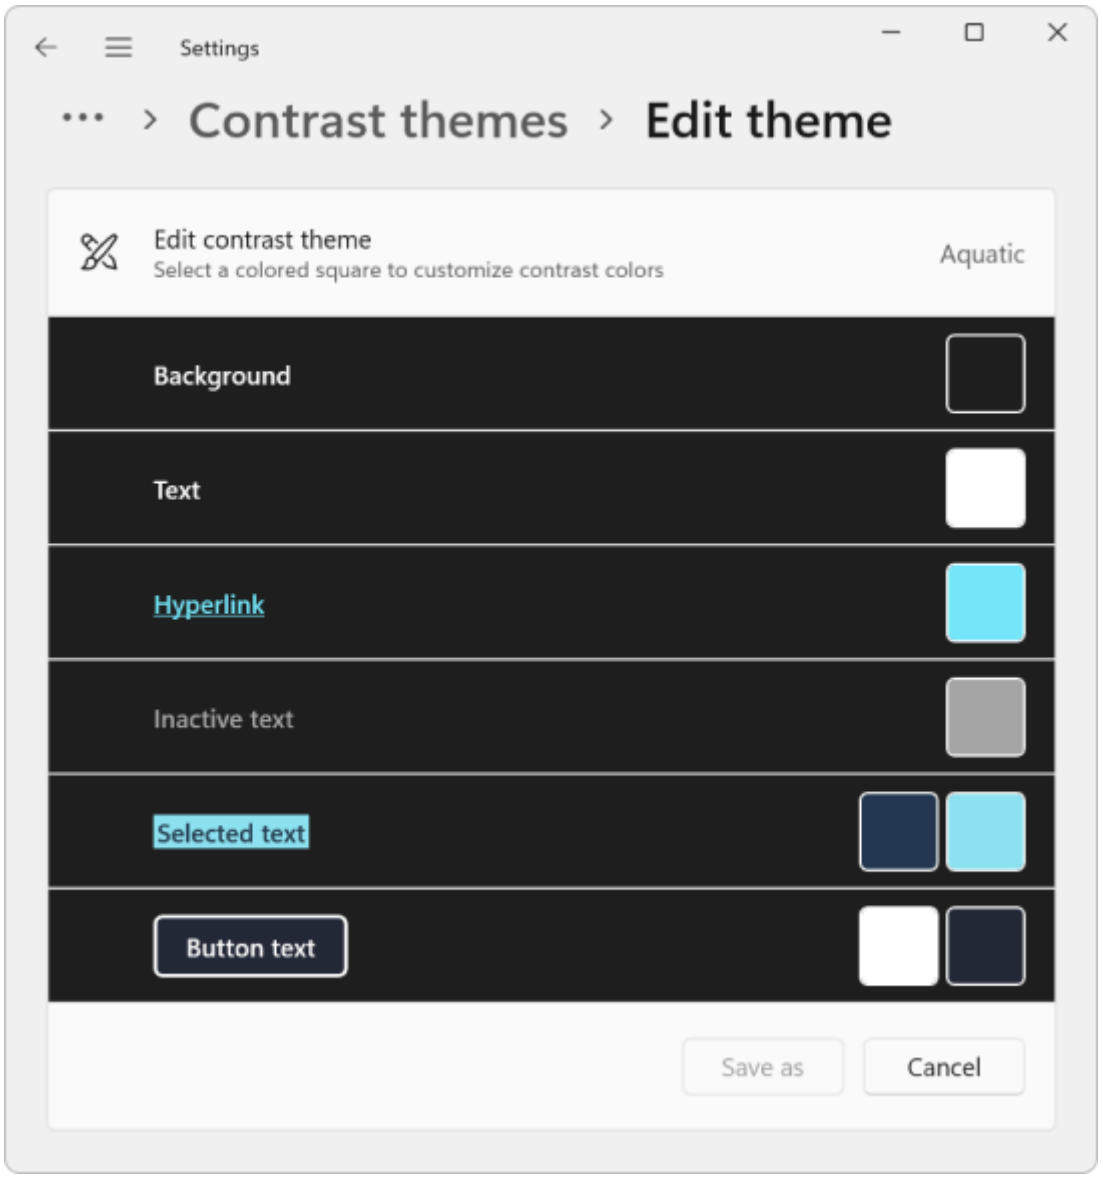
            <!-- HighContrast is used in all high contrast themes -->
            <ResourceDictionary x:Key="HighContrast">
                <SolidColorBrush x:Key="BrandedPageBackgroundBrush"
Color="{ThemeResource SystemColorWindowColor}" />
            </ResourceDictionary>
        </ResourceDictionary.ThemeDictionaries>
    </ResourceDictionary>
</Application.Resources>
```

Contrast colors

On the *Settings* > *Ease of access* > *Contrast themes* page (shown in the following image), users can select from four default contrast themes: **Aquatic**, **Desert**, **Dusk**, and **Night sky**.



After the user selects an option, they can choose to immediately apply it, or they can edit the theme. The following image shows the Edit theme dialog for the **Aquatic** contrast theme.



This table shows the contrast theme colors and their recommended pairings. Each **SystemColor** resource is a variable that automatically updates the color when the user switches contrast themes.

Expand table

Color swatch	Description
	SystemColorWindowColor Background of pages, panes, popups, and windows. Pair with **SystemColorWindowTextColor**
	SystemColorWindowTextColor Headings, body copy, lists, placeholder text, app and window borders, any UI that can't be interacted with. Pair with **SystemColorWindowColor**

Color swatch	Description
	SystemColorHotlightColor Hyperlinks. Pair with **SystemColorWindowColor**
	**SystemColorGrayTextColor** Inactive or disabled UI. Pair with **SystemColorWindowColor**
	SystemColorHighlightTextColor Foreground color of text or UI that is selected, interacted with (hover, pressed), or in progress. Pair with **SystemColorHighlightColor**
	SystemColorHighlightColor Background or accent color of UI that is selected, interacted with (hover, pressed), or in progress. Pair with **SystemColorHighlightTextColor**
	**SystemColorButtonTextColor** Foreground color of buttons and any UI that can be interacted with. Pair with **SystemColorButtonFaceColor**
	**SystemColorButtonFaceColor** Background color of buttons and any UI that can be interacted with. Pair with **SystemColorButtonTextColor**

The next table shows how the colors appear when used on a background set to **SystemColorWindowColor**.

Expand table

Example	Values
	SystemColorWindowTextColor
	SystemColorHotlightColor
	SystemColorGrayTextColor
	SystemColorHighlightTextColor + SystemColorHighlightColor
	SystemColorButtonTextColor + SystemColorButtonFaceColor

In the following code snippet, we show how to pick a resource for **BrandedPageBackgroundBrush**. **SystemColorWindowColor** is a good choice here as **BrandedPageBackgroundBrush** indicates that it will be used for a background.

XAML

```
<Application.Resources>
    <ResourceDictionary>
        <ResourceDictionary.ThemeDictionaries>
            <!-- Default is a fallback if a more precise theme isn't called
            out below -->
            <ResourceDictionary x:Key="Default">
                <SolidColorBrush x:Key="BrandedPageBackgroundBrush"
Color="#E6E6E6" />
            </ResourceDictionary>

            <!-- Optional, Light is used in light theme.
            If included, Default will be used for Dark theme -->
            <ResourceDictionary x:Key="Light">
                <SolidColorBrush x:Key="BrandedPageBackgroundBrush"
Color="#E6E6E6" />
            </ResourceDictionary>

            <!-- HighContrast is used in all high contrast themes -->
            <ResourceDictionary x:Key="HighContrast">
                <SolidColorBrush x:Key="BrandedPageBackgroundBrush" Color="
{ThemeResource SystemColorWindowColor}" />
            </ResourceDictionary>
        </ResourceDictionary.ThemeDictionaries>
    </ResourceDictionary>
</Application.Resources>
```

The resource is then assigned to the background of an element.

XAML

```
<Grid Background="{ThemeResource BrandedPageBackgroundBrush}">
```

We use `{ThemeResource}` twice in the preceding example, once to reference **SystemColorWindowColor** and again to reference **BrandedPageBackgroundBrush**. Both are required for your app to theme correctly at run time. This is a good time to test out the functionality in your app. The **Grid** background will automatically update as you switch to a high contrast theme. It will also update when switching between different high contrast themes.

> ⓘ **Note**
>
> **WinUI 2.6 and newer**

There are eight high contrast system brushes available for referencing through a **ResourceKey** (see the following example for **SystemColorWindowTextColorBrush**).

```
<StaticResource x:Key="MyControlBackground"
ResourceKey="SystemColorWindowTextColorBrush" />
```

The brush names match one of the eight previously mentioned system colors exactly (with "Brush" appended). We recommend using a **StaticResource** instead of a local **SolidColorBrush** for performance reasons.

Best practices

Here are some recommendations for customizing the contrast theme colors in your Windows app.

- Test in all four high contrast themes while your app is running.
- Be consistent.
- Make sure **HighContrastAdjustment** is set to `None` in your app (it is turned on by default). See Setting HighContrastAdjustment to None.
- **Do not** hard code a color in the HighContrast theme. Instead, use the **SystemColor** `Color` and `ColorBrush` resources. For more detail, see Hard-coded colors.
- **Do not** mix background/foreground pairs that are not compatible
- **Do not** choose color resource for aesthetics. Remember, the colors change with the theme.
- **Do not** use `SystemColorGrayTextColor` for body copy that is secondary or acts as hint text. This is intended for disabled content only.
- **Do not** use `SystemColorHotlightColor` and corresponding brush as both are reserved for hyperlinks.

Tip

It's often helpful to look at the WinUI Gallery app to see how common controls use the **SystemColor** brushes. If installed already, open them by clicking the following links: WinUI 3 Gallery or WinUI 2 Gallery.

If they are not installed, you can download the WinUI 3 Gallery and the WinUI 2 Gallery from the Microsoft Store.

You can also get the source code for both from GitHub (use the *main* branch for WinUI 3 and the *winui2* branch for WinUI 2).

Hard-coded colors

Platform controls provide built-in support for contrast themes, but you should be careful when customizing your application UI. Two of the most common issues occur when either the color of an element is hard-coded or an incorrect **SystemColor** resource is used.

In the following code snippet, we show a Grid element declared with a background color set to `#E6E6E6` (a very light grey). If you hard-code the color in this way, you also override the background color across all themes. For example, if the user selects the **Aquatic** contrast theme, instead of white text on a near black background, the text color in this app changes to white while the background remains light grey. The very low contrast between text and background could make this app very difficult to use.

XAML

```
<Grid Background="#E6E6E6">
```

Instead, we recommend using the **{ThemeResource} markup extension** to reference a color in the **ThemeDictionaries** collection of a **ResourceDictionary**. This enables the automatic substitution of colors and brushes based on the user's current theme.

XAML

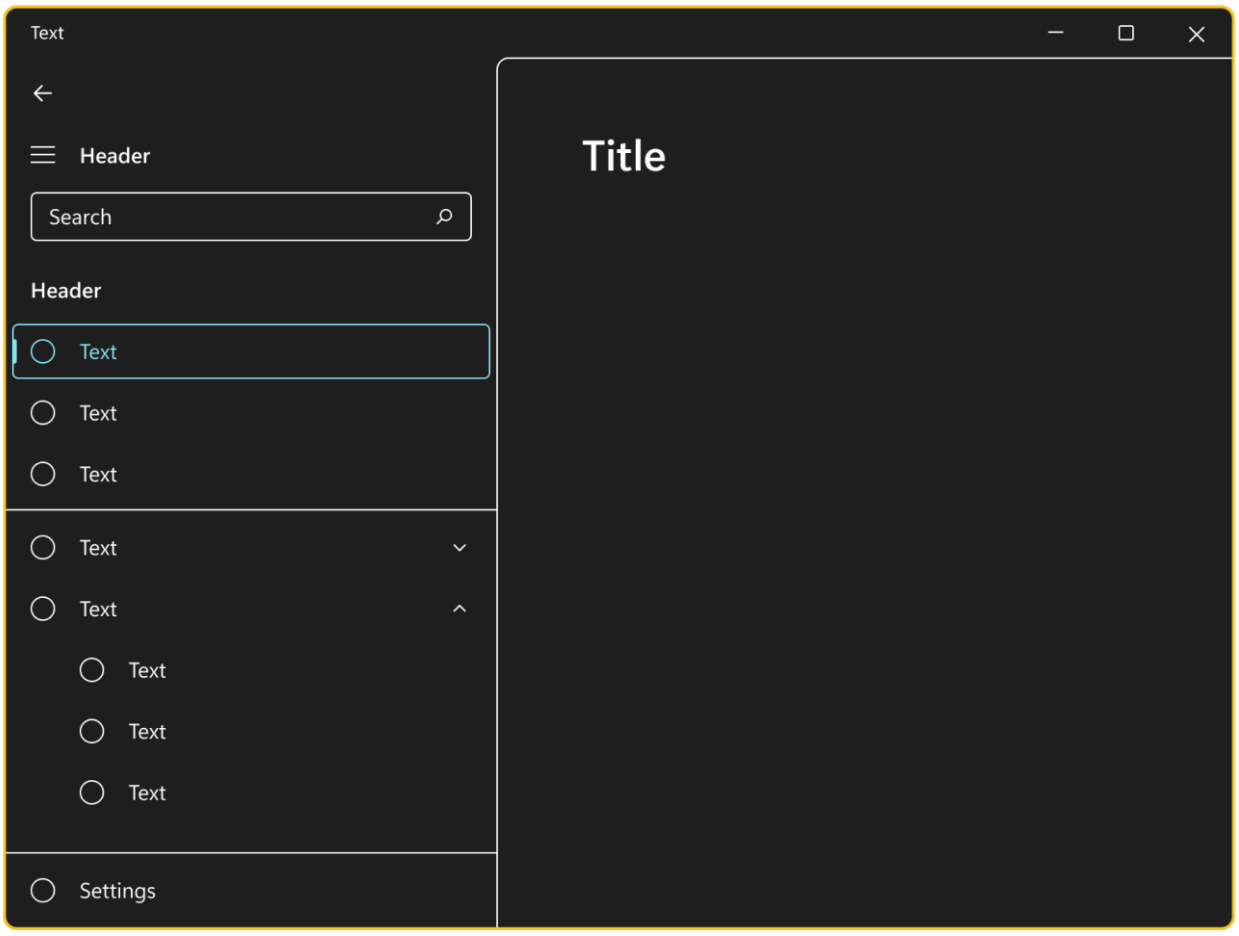
```
<Grid Background="{ThemeResource BrandedPageBackgroundBrush}">
```

Borders

Pages, panes, popups, and bars should all use **SystemColorWindowColor** for their background. Add a contrast theme-only border only where necessary to preserve important boundaries in your UI.

> **Tip**
>
> We recommend using 2px borders for transitory surfaces such as flyouts and dialogs.

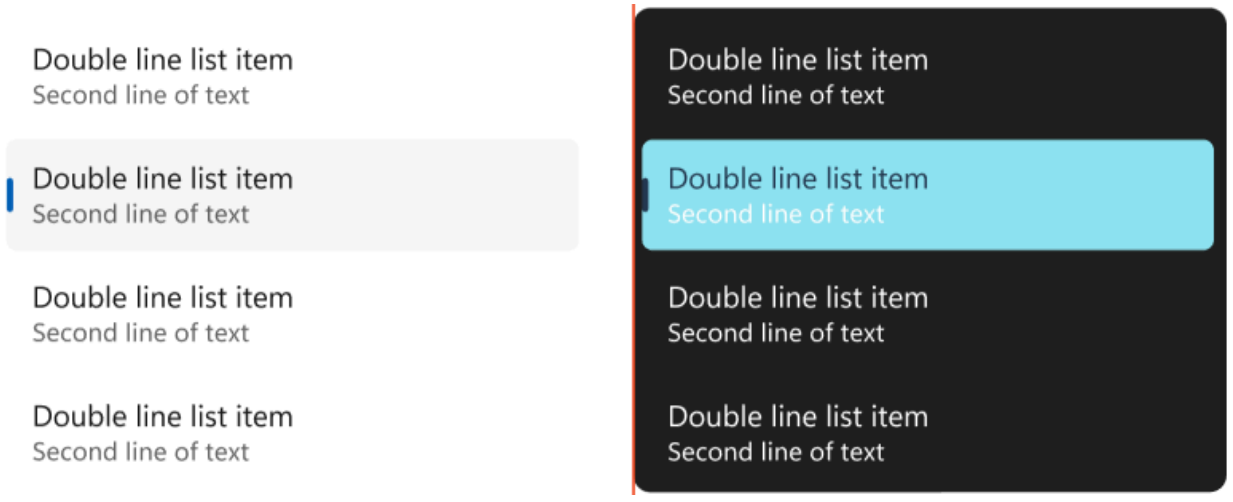
The navigation pane and the page both share the same background color in contrast themes. To distinguish them, a contrast theme-only border is essential.



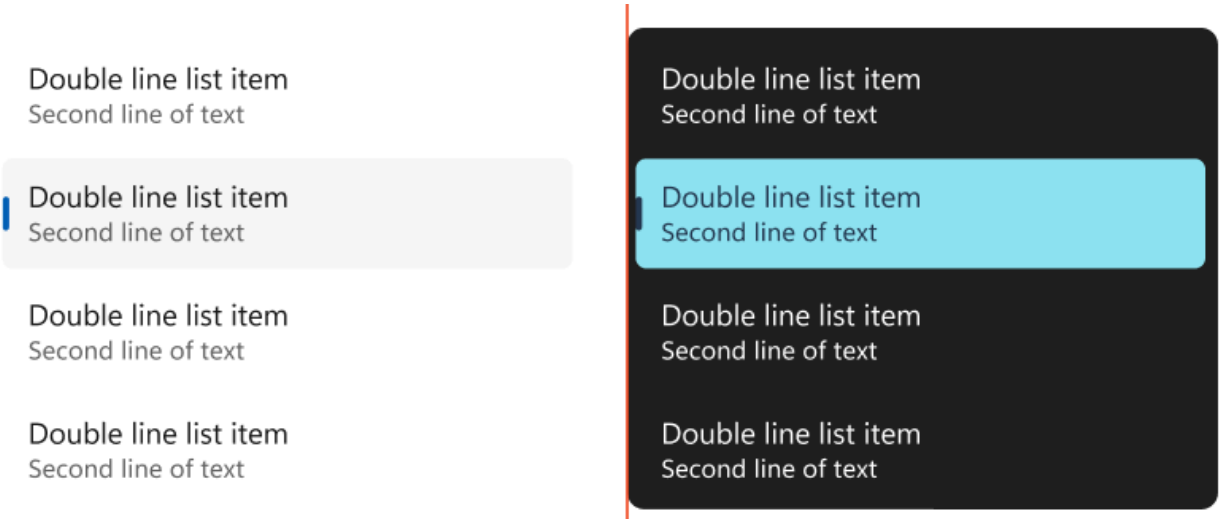
List items with colored text

In contrast themes, items in a ListView have their background set to **SystemColorHighlightColor** when the user hovers over, presses, or selects them. A common issue with complex list items occurs when the content of the list item fails to invert its color, making the items impossible to read.

Be careful when you set the TextBlock.Foreground in the DataTemplate of the **ListView** (typically done to establish visual hierarchy). The **Foreground** property is set on the **ListViewItem**, and each **TextBlock** in the DataTemplate inherits the correct **Foreground** color. Setting **Foreground** breaks this inheritance.



You can resolve this by setting **Foreground** conditionally through a **Style** in a ThemeDictionaries collection. As the **Foreground** is not set by **SecondaryBodyTextBlockStyle** in **HighContrast**, the color will invert correctly.



The following code snippet (from an App.xaml file) shows an example ThemeDictionaries collection in a **ListView** data template.

XAML

```
<ResourceDictionary.ThemeDictionaries>
    <ResourceDictionary x:Key="Default">
        <Style
            x:Key="SecondaryBodyTextBlockStyle"
            TargetType="TextBlock"
            BasedOn="{StaticResource BodyTextBlockStyle}">
            <Setter Property="Foreground"
                Value="{StaticResource
SystemControlForegroundBaseMediumBrush}" />
        </Style>
    </ResourceDictionary>

    <ResourceDictionary x:Key="Light">
        <Style
            x:Key="SecondaryBodyTextBlockStyle"
            TargetType="TextBlock"
            BasedOn="{StaticResource BodyTextBlockStyle}">
            <Setter Property="Foreground"
                Value="{StaticResource
SystemControlForegroundBaseMediumBrush}" />
        </Style>
    </ResourceDictionary>

    <ResourceDictionary x:Key="HighContrast">
        <!-- The Foreground Setter is omitted in HighContrast -->
        <Style
            x:Key="SecondaryBodyTextBlockStyle"
            TargetType="TextBlock"
            BasedOn="{StaticResource BodyTextBlockStyle}" />
```

```
    </ResourceDictionary>
</ResourceDictionary.ThemeDictionaries>

<!-- Usage in your DataTemplate... -->
<DataTemplate>
    <StackPanel>
        <TextBlock Style="{StaticResource BodyTextBlockStyle}" Text="Double
line list item" />

        <!-- Note how ThemeResource is used to reference the Style -->
        <TextBlock Style="{ThemeResource SecondaryBodyTextBlockStyle}"
Text="Second line of text" />
    </StackPanel>
</DataTemplate>
```

Accessible text requirements

Article • 11/27/2024

This topic describes best practices for accessibility of text in an app, by assuring that colors and backgrounds satisfy the necessary contrast ratio. This topic also discusses the Microsoft UI Automation roles that text elements in a Universal Windows Platform (UWP) app can have, and best practices for text in graphics.

Contrast ratios

Although users always have the option to switch to a high-contrast mode, your app design for text should regard that option as a last resort. A much better practice is to make sure that your app text meets certain established guidelines for the level of contrast between text and its background. Evaluation of the level of contrast is based on deterministic techniques that do not consider color hue. For example, if you have red text on a green background, that text might not be readable to someone with a color blindness impairment. Checking and correcting the contrast ratio can prevent these types of accessibility issues.

The recommendations for text contrast documented here are based on a web accessibility standard, G18: Ensuring that a contrast ratio of at least 4.5:1 exists between text (and images of text) and background behind the text. This guidance exists in the *W3C Techniques for WCAG 2.0* specification.

To be considered accessible, visible text must have a minimum luminosity contrast ratio of 4.5:1 against the background. Exceptions include logos and incidental text, such as text that is part of an inactive UI component.

Text that is decorative and conveys no information is excluded. For example, if random words are used to create a background, and the words can be rearranged or substituted without changing meaning, the words are considered to be decorative and do not need to meet this criterion.

Use color contrast tools to verify that the visible text contrast ratio is acceptable. See Techniques for WCAG 2.0 G18 (Resources section) for tools that can test contrast ratios.

> **Note**
>
> Some of the tools listed by Techniques for WCAG 2.0 G18 can't be used interactively with a UWP app. You may need to enter foreground and background

color values manually in the tool, or make screen captures of app UI and then run the contrast ratio tool over the screen capture image.

Text element roles

A UWP app can use these default elements (commonly called *text elements* or *textedit controls*):

- **TextBlock**: role is **Text**
- **TextBox**: role is **Edit**
- **RichTextBlock** (and overflow class **RichTextBlockOverflow**): role is **Text**
- **RichEditBox**: role is **Edit**

When a control reports that is has a role of **Edit**, assistive technologies assume that there are ways for users to change the values. So if you put static text in a **TextBox**, you are misreporting the role and thus misreporting the structure of your app to the accessibility user.

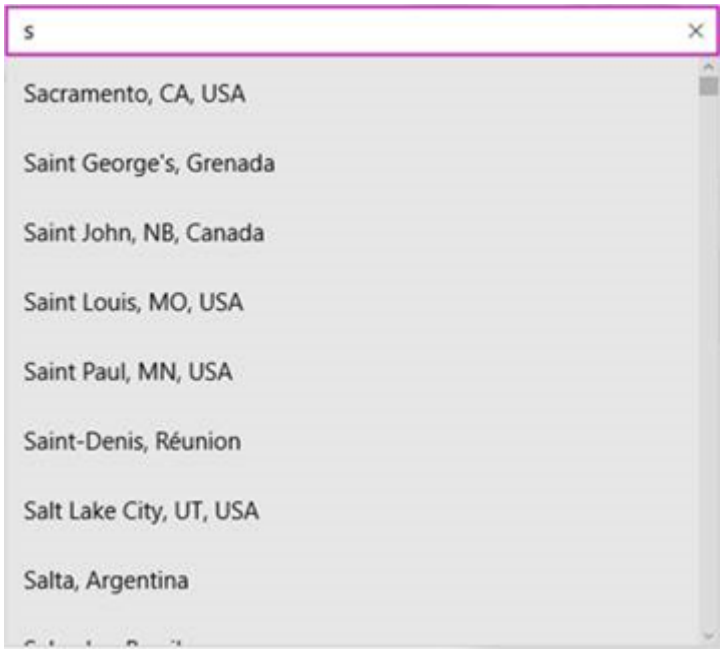
In the text models for XAML, there are two elements that are primarily used for static text, **TextBlock** and **RichTextBlock**. Neither of these are a **Control** subclass, and as such neither of them are keyboard-focusable or can appear in the tab order. But that does not mean that assistive technologies can't or won't read them. Screen readers are typically designed to support multiple modes of reading the content in an app, including a dedicated reading mode or navigation patterns that go beyond focus and the tab order, like a "virtual cursor". So don't put your static text into focusable containers just so that tab order gets the user there. Assistive technology users expect that anything in the tab order is interactive, and if they encounter static text there, that is more confusing than helpful. You should test this out yourself with Narrator to get a sense of the user experience with your app when using a screen reader to examine your app's static text.

Auto-suggest accessibility

When a user types into an entry field and a list of potential suggestions appears, this type of scenario is called auto-suggest. This is common in the **To:** line of a mail field, the Cortana search box in Windows, the URL entry field in Microsoft Edge, the location entry field in the Weather app, and so on. If you are using a XAML **AutosuggestBox** or the HTML intrinsic controls, then this experience is already hooked up for you by default. To make this experience accessible the entry field and the list must be associated. This is explained in the Implementing auto-suggest section.

Narrator has been updated to make this type of experience accessible with a special suggestions mode. At a high level, when the edit field and list are connected properly the end user will:

- Know the list is present and when the list closes
- Know how many suggestions are available
- Know the selected item, if any
- Be able to move Narrator focus to the list
- Be able to navigate through a suggestion with all other reading modes



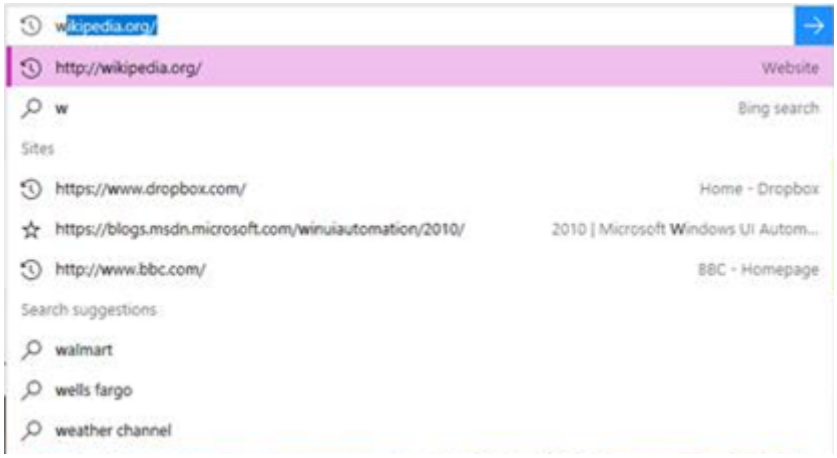
Example of a suggestion list

Implementing auto-suggest

To make this experience accessible the entry field and the list must be associated in the UIA tree. This association is done with the UIA_ControllerForPropertyId property in desktop apps or the ControlledPeers property in UWP apps.

At a high level there are 2 types of auto-suggest experiences.

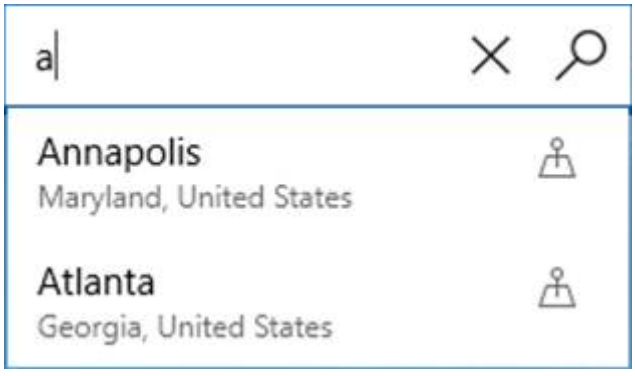
Default selection
If a default selection is made in the list, Narrator looks for a **UIA_SelectionItem_ElementSelectedEventId** event in a desktop app, or the **AutomationEvents.SelectionItemPatternOnElementSelected** event to be fired in a UWP app. Every time the selection changes, when the user types another letter and the suggestions have been updated or when a user navigates through the list, the **ElementSelected** event should be fired.



Example where there is a default selection

No default selection

If there is no default selection, such as in the Weather app's location box, then Narrator looks for the desktop **UIA_LayoutInvalidatedEventId** event or the UWP **LayoutInvalidated** event to be fired on the list every time the list is updated.



Example where there is no default selection

XAML implementation

If you are using the default XAML **AutosuggestBox**, then everything is already hooked up for you. If you are making your own auto-suggest experience using a **TextBox** and a list then you will need to set the list as **AutomationProperties.ControlledPeers** on the **TextBox**. You must fire the **AutomationPropertyChanged** event for the **ControlledPeers** property every time you add or remove this property and also fire your own **SelectionItemPatternOnElementSelected** events or **LayoutInvalidated** events depending on your type of scenario, which was explained previously in this article.

HTML implementation

If you are using the intrinsic controls in HTML, then the UIA implementation has already been mapped for you. Below is an example of an implementation that is already hooked up for you:

HTML

```
<label>Sites <input id="input1" type="text" list="datalist1" /></label>
<datalist id="datalist1">
        <option value="http://www.google.com/" label="Google"></option>
        <option value="http://www.reddit.com/" label="Reddit"></option>
</datalist>
```

If you are creating your own controls, you must set up your own ARIA controls, which are explained in the W3C standards.

Text in graphics

Whenever possible, avoid including text in a graphic. For example, any text that you include in the image source file that is displayed in the app as an **Image** element is not automatically accessible or readable by assistive technologies. If you must use text in graphics, make sure that the **AutomationProperties.Name** value that you provide as the equivalent of "alt text" includes that text or a summary of the text's meaning. Similar considerations apply if you are creating text characters from vectors as part of a **Path**, or by using **Glyphs**.

Text font size and scale

Users can have difficulty reading text in an app when the fonts uses are simply too small, so make sure any text in your application is a reasonable size in the first place.

Once you've done the obvious, Windows includes various accessibility tools and settings that users can take advantage of and adjust to their own needs and preferences for reading text. These include:

- The Magnifier tool, which enlarges a selected area of the UI. You should ensure the layout of text in your app doesn't make it difficult to use Magnifier for reading.
- Global scale and resolution settings in **Settings->System->Display->Scale and layout**. Exactly which sizing options are available can vary as this depends on the capabilities of the display device.
- Text size settings in **Settings->Ease of access->Display**. Adjust the **Make text bigger** setting to specify only the size of text in supporting controls across all applications and screens (all UWP text controls support the text scaling experience without any customization or templating).

> ⓘ Note

The **Make everything bigger** setting lets a user specify their preferred size for text and apps in general on their primary screen only.

Various text elements and controls have an **IsTextScaleFactorEnabled** property. This property has the value **true** by default. When **true**, the size of text in that element can be scaled. The scaling affects text that has a small **FontSize** to a greater degree than it affects text that has a large **FontSize**. You can disable automatic resizing by setting an element's **IsTextScaleFactorEnabled** property to **false**.

See Text scaling for more details.

Add the following markup to an app and run it. Adjust the **Text size** setting, and see what happens to each **TextBlock**.

XAML

```xml
<TextBlock Text="In this case, IsTextScaleFactorEnabled has been left set to its default value of true."
    Style="{StaticResource BodyTextBlockStyle}"/>

<TextBlock Text="In this case, IsTextScaleFactorEnabled has been set to false."
    Style="{StaticResource BodyTextBlockStyle}"
IsTextScaleFactorEnabled="False"/>
```

We don't recommend that you disable text scaling as scaling UI text universally across all apps is an important accessibility experience for users.

You can also use the **TextScaleFactorChanged** event and the **TextScaleFactor** property to find out about changes to the **Text size** setting on the phone. Here's how:

C#

```
{
    ...
    var uiSettings = new Windows.UI.ViewManagement.UISettings();
    uiSettings.TextScaleFactorChanged += UISettings_TextScaleFactorChanged;
    ...
}

private async void
UISettings_TextScaleFactorChanged(Windows.UI.ViewManagement.UISettings
sender, object args)
{
```

```
    var messageDialog = new
Windows.UI.Popups.MessageDialog(string.Format("It's now {0}",
sender.TextScaleFactor), "The text scale factor has changed");
    await messageDialog.ShowAsync();
}
```

The value of **TextScaleFactor** is a double in the range [1,2.25]. The smallest text is scaled up by this amount. You might be able to use the value to, say, scale graphics to match the text. But remember that not all text is scaled by the same factor. Generally speaking, the larger text is to begin with, the less it's affected by scaling.

These types have an **IsTextScaleFactorEnabled** property:

- **ContentPresenter**
- **Control** and derived classes
- **FontIcon**
- **RichTextBlock**
- **TextBlock**
- **TextElement** and derived classes

Examples

Open the WinUI 3 Gallery app and see text accessibility support in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Accessibility practices to avoid

Article • 01/04/2023

If you want to create an accessible Windows app, see this list of practices to avoid:

- **Avoid building custom UI elements if you can use the default Windows controls** or controls that have already implemented Microsoft UI Automation support. Standard Windows controls are accessible by default and usually require adding only a few accessibility attributes that are app-specific. In contrast, implementing the **AutomationPeer** support for a true custom control is somewhat more involved (see Custom automation peers).

- **Don't put static text or other non-interactive elements into the tab order** (for example, by setting the **TabIndex** property for an element that is not interactive). If non-interactive elements are in the tab order, that is against keyboard accessibility guidelines because it decreases efficiency of keyboard navigation for users. Many assistive technologies use tab order and the ability to focus an element as part of their logic for how to present an app's interface to the assistive technology user. Text-only elements in the tab order can confuse users who expect only interactive elements in the tab order (buttons, check boxes, text input fields, combo boxes, lists, and so on).

- **Avoid using absolute positioning of UI elements** (such as in a **Canvas** element) because the presentation order often differs from the child element declaration order (which is the de facto logical order). Whenever possible, arrange UI elements in document or logical order to ensure that screen readers can read those elements in the correct order. If the visible order of UI elements can diverge from the document or logical order, use explicit tab index values (set **TabIndex**) to define the correct reading order.

- **Don’t use color as the only way to convey information.** Users who are color blind cannot receive information that is conveyed only through color, such as in a color status indicator. Include other visual cues, preferably text, to ensure that information is accessible.

- **Don’t automatically refresh an entire app canvas** unless it is really necessary for app functionality. If you need to automatically refresh page content, update only certain areas of the page. Assistive technologies generally must assume that a refreshed app canvas is a totally new structure, even if the effective changes were minimal. The cost of this to the assistive technology user is that any document

view or description of the refreshed app now must be recreated and presented to the user again.

A deliberate page navigation that is initiated by the user is a legitimate case for refreshing the app's structure. But make sure that the UI item that initiates the navigation is correctly identified or named to give some indication that invoking it will result in a context change and page reload.

> ⓘ **Note**
>
> If you do refresh content within a region, consider setting the **AccessibilityProperties.LiveSetting** accessibility property on that element to one of the non-default settings **Polite** or **Assertive**. Some assistive technologies can map this setting to the Accessible Rich Internet Applications (ARIA) concept of live regions and can thus inform the user that a region of content has changed.

- **Don’t use UI elements that flash more than three times per second.** Flashing elements can cause some people to have seizures. It is best to avoid using UI elements that flash.
- **Don’t change user context or activate functionality automatically.** Context or activation changes should occur only when the user takes a direct action on a UI element that has focus. Changes in user context include changing focus, displaying new content, and navigating to a different page. Making context changes without involving the user can be disorienting for users who have disabilities. The exceptions to this requirement include displaying submenus, validating forms, displaying help text in another control, and changing context in response to an asynchronous event.

Custom automation peers

Article • 01/04/2023

Describes the concept of automation peers for Microsoft UI Automation, and how you can provide automation support for your own custom UI class.

UI Automation provides a framework that automation clients can use to examine or operate the user interfaces of a variety of UI platforms and frameworks. If you are writing a Windows app, the classes that you use for your UI already provide UI Automation support. You can derive from existing, non-sealed classes to define a new kind of UI control or support class. In the process of doing so, your class might add behavior that should have accessibility support but that the default UI Automation support does not cover. In this case, you should extend the existing UI Automation support by deriving from the **AutomationPeer** class that the base implementation used, adding any necessary support to your peer implementation, and informing the Windows app control infrastructure that it should create your new peer.

UI Automation enables not only accessibility applications and assistive technologies, such as screen readers, but also quality-assurance (test) code. In either scenario, UI Automation clients can examine user-interface elements and simulate user interaction with your app from other code outside your app. For info about UI Automation across all platforms and in its wider meaning, see UI Automation Overview.

There are two distinct audiences who use the UI Automation framework.

- **UI Automation *clients*** call UI Automation APIs to learn about all of the UI that is currently displayed to the user. For example, an assistive technology such as a screen reader acts as a UI Automation client. The UI is presented as a tree of automation elements that are related. The UI Automation client might be interested in just one app at a time, or in the entire tree. The UI Automation client can use UI Automation APIs to navigate the tree and to read or change information in the automation elements.
- **UI Automation *providers*** contribute information to the UI Automation tree, by implementing APIs that expose the elements in the UI that they introduced as part of their app. When you create a new control, you should now act as a participant in the UI Automation provider scenario. As a provider, you should ensure that all UI Automation clients can use the UI Automation framework to interact with your control for both accessibility and testing purposes.

Typically there are parallel APIs in the UI Automation framework: one API for UI Automation clients and another, similarly named API for UI Automation providers. For

the most part, this topic covers the APIs for the UI Automation provider, and specifically the classes and interfaces that enable provider extensibility in that UI framework. Occasionally we mention UI Automation APIs that the UI Automation clients use, to provide some perspective, or provide a lookup table that correlates the client and provider APIs. For more info about the client perspective, see UI Automation Client Programmer's Guide.

> **Note**
>
> UI Automation clients don't typically use managed code and aren't typically implemented as a UWP app (they are usually desktop apps). UI Automation is based on a standard and not a specific implementation or framework. Many existing UI Automation clients, including assistive technology products such as screen readers, use Component Object Model (COM) interfaces to interact with UI Automation, the system, and the apps that run in child windows. For more info on the COM interfaces and how to write a UI Automation client using COM, see UI Automation Fundamentals.

Determining the existing state of UI Automation support for your custom UI class

Before you attempt to implement an automation peer for a custom control, you should test whether the base class and its automation peer already provides the accessibility or automation support that you need. In many cases, the combination of the **FrameworkElementAutomationPeer** implementations, specific peers, and the patterns they implement can provide a basic but satisfactory accessibility experience. Whether this is true depends on how many changes you made to the object model exposure to your control versus its base class. Also, this depends on whether your additions to base class functionality correlate to new UI elements in the template contract or to the visual appearance of the control. In some cases your changes might introduce new aspects of user experience that require additional accessibility support.

Even if using the existing base peer class provides the basic accessibility support, it is still a best practice to define a peer so that you can report precise **ClassName** information to UI Automation for automated testing scenarios. This consideration is especially important if you are writing a control that is intended for third-party consumption.

Automation peer classes

The UWP builds on existing UI Automation techniques and conventions used by previous managed-code UI frameworks such as Windows Forms, Windows Presentation Foundation (WPF) and Microsoft Silverlight. Many of the control classes and their function and purpose also have their origin in a previous UI framework.

By convention, peer class names begin with the control class name and end with "AutomationPeer". For example, **ButtonAutomationPeer** is the peer class for the **Button** control class.

> **Note**
>
> For purposes of this topic, we treat the properties that are related to accessibility as being more important when you implement a control peer. But for a more general concept of UI Automation support, you should implement a peer in accordance with recommendations as documented by the UI Automation Provider Programmer's Guide and UI Automation Fundamentals. Those topics don't cover the specific AutomationPeer APIs that you would use to provide the information in the UWP framework for UI Automation, but they do describe the properties that identify your class or provide other information or interaction.

Peers, patterns and control types

A *control pattern* is an interface implementation that exposes a particular aspect of a control's functionality to a UI Automation client. UI Automation clients use the properties and methods exposed through a control pattern to retrieve information about capabilities of the control, or to manipulate the control's behavior at run time.

Control patterns provide a way to categorize and expose a control's functionality independent of the control type or the appearance of the control. For example, a control that presents a tabular interface uses the **Grid** control pattern to expose the number of rows and columns in the table, and to enable a UI Automation client to retrieve items from the table. As other examples, the UI Automation client can use the **Invoke** control pattern for controls that can be invoked, such as buttons, and the **Scroll** control pattern for controls that have scroll bars, such as list boxes, list views, or combo boxes. Each control pattern represents a separate type of functionality, and control patterns can be combined to describe the full set of functionality supported by a particular control.

Control patterns relate to UI as interfaces relate to COM objects. In COM, you can query an object to ask what interfaces it supports and then use those interfaces to access functionality. In UI Automation, UI Automation clients can query a UI Automation element to find out which control patterns it supports, and then interact with the

element and its peered control through the properties, methods, events, and structures exposed by the supported control patterns.

One of the main purposes of an automation peer is to report to a UI Automation client which control patterns the UI element can support through its peer. To do this, UI Automation providers implement new peers that change the **GetPattern** method behavior by overriding the **GetPatternCore** method. UI Automation clients make calls that the UI Automation provider maps to calling **GetPattern**. UI Automation clients query for each specific pattern that they want to interact with. If the peer supports the pattern, it returns an object reference to itself; otherwise it returns **null**. If the return is not **null**, the UI Automation client expects that it can call APIs of the pattern interface as a client, in order to interact with that control pattern.

A *control type* is a way to broadly define the functionality of a control that the peer represents. This is a different concept than a control pattern because while a pattern informs UI Automation what info it can get or what actions it can perform through a particular interface, the control type exists one level above that. Each control type has guidance about these aspects of UI Automation:

- UI Automation control patterns: A control type might support more than one pattern, each of which represents a different classification of info or interaction. Each control type has a set of control patterns that the control must support, a set that is optional, and a set that the control must not support.
- UI Automation property values: Each control type has a set of properties that the control must support. These are the general properties, as described in UI Automation Properties Overview, not the ones that are pattern-specific.
- UI Automation events: Each control type has a set of events that the control must support. Again these are general, not pattern-specific, as described in UI Automation Events Overview.
- UI Automation tree structure: Each control type defines how the control must appear in the UI Automation tree structure.

Regardless of how automation peers for the framework are implemented, UI Automation client functionality isn't tied to the UWP, and in fact it's likely that existing UI Automation clients such as assistive technologies will use other programming models, such as COM. In COM, clients can **QueryInterface** for the COM control pattern interface that implements the requested pattern or the general UI Automation framework for properties, events or tree examination. For the patterns, the UI Automation framework marshals that interface code across into UWP code running against the app's UI Automation provider and the relevant peer.

When you implement control patterns for a managed-code framework such as a UWP app using C# or Microsoft Visual Basic, you can use .NET Framework interfaces to represent these patterns instead of using the COM interface representation. For example, the UI Automation pattern interface for a Microsoft .NET provider implementation of the **Invoke** pattern is **IInvokeProvider**.

For a list of control patterns, provider interfaces, and their purpose, see Control patterns and interfaces. For the list of the control types, see UI Automation Control Types Overview.

Guidance for how to implement control patterns

The control patterns and what they're intended for are part of a larger definition of the UI Automation framework, and don't just apply to the accessibility support for a UWP app. When you implement a control pattern you should make sure you're implementing it in a way that matches the guidance as documented in these docs and also in the UI Automation specification. If you're looking for guidance, you can generally use the Microsoft documentation and won't need to refer to the specification. Guidance for each pattern is documented here: Implementing UI Automation Control Patterns. You'll notice that each topic under this area has an "Implementation Guidelines and Conventions" section and "Required Members" section. The guidance usually refers to specific APIs of the relevant control pattern interface in the Control Pattern Interfaces for Providers reference. Those interfaces are the native/COM interfaces (and their APIs use COM-style syntax). But everything you see there has an equivalent in the **Windows.UI.Xaml.Automation.Provider** namespace.

If you're using the default automation peers and expanding on their behavior, those peers have already been written in conformance to UI Automation guidelines. If they support control patterns, you can rely on that pattern support conforming with guidance at Implementing UI Automation Control Patterns. If a control peer reports that it's representative of a control type defined by UI Automation, then the guidance documented at Supporting UI Automation Control Types has been followed by that peer.

Nevertheless you might need additional guidance for control patterns or control types in order to follow the UI Automation recommendations in your peer implementation. That would be particularly true if you're implementing pattern or control type support that doesn't yet exist as a default implementation in a UWP control. For example, the pattern for annotations isn't implemented in any of the default XAML controls. But you might have an app that uses annotations extensively and therefore you want to surface that functionality to be accessible. For this scenario, your peer should implement

IAnnotationProvider and should probably report itself as the **Document** control type with appropriate properties to indicate that your documents support annotation.

We recommend that you use the guidance that you see for the patterns under Implementing UI Automation Control Patterns or control types under Supporting UI Automation Control Types as orientation and general guidance. You might even try following some of the API links for descriptions and remarks as to the purpose of the APIs. But for syntax specifics that are needed for UWP app programming, find the equivalent API within the **Windows.UI.Xaml.Automation.Provider** namespace and use those reference pages for more info.

Built-in automation peer classes

In general, elements implement an automation peer class if they accept UI activity from the user, or if they contain information needed by users of assistive technologies that represent the interactive or meaningful UI of apps. Not all UWP visual elements have automation peers. Examples of classes that implement automation peers are **Button** and **TextBox**. Examples of classes that do not implement automation peers are **Border** and classes based on **Panel**, such as **Grid** and **Canvas**. A **Panel** has no peer because it is providing a layout behavior that is visual only. There is no accessibility-relevant way for the user to interact with a **Panel**. Whatever child elements a **Panel** contains are instead reported to UI Automation trees as child elements of the next available parent in the tree that has a peer or element representation.

UI Automation and UWP process boundaries

Typically, UI Automation client code that accesses a UWP app runs out-of-process. The UI Automation framework infrastructure enables information to get across the process boundary. This concept is explained in more detail in UI Automation Fundamentals.

OnCreateAutomationPeer

All classes that derive from **UIElement** contain the protected virtual method **OnCreateAutomationPeer**. The object initialization sequence for automation peers calls **OnCreateAutomationPeer** to get the automation peer object for each control and thus to construct a UI Automation tree for run-time use. UI Automation code can use the peer to get information about a control's characteristics and features and to simulate interactive use by means of its control patterns. A custom control that supports automation must override **OnCreateAutomationPeer** and return an instance of a class that derives from **AutomationPeer**. For example, if a custom control derives from the

ButtonBase class, the object returned by **OnCreateAutomationPeer** should derive from ButtonBaseAutomationPeer.

If you're writing a custom control class and intend to also supply a new automation peer, you should override the OnCreateAutomationPeer method for your custom control so that it returns a new instance of your peer. Your peer class must derive directly or indirectly from AutomationPeer.

For example, the following code declares that the custom control `NumericUpDown` should use the peer `NumericUpDownPeer` for UI Automation purposes.

C#

```
using Windows.UI.Xaml.Automation.Peers;
...
public class NumericUpDown : RangeBase {
    public NumericUpDown() {
    // other initialization; DefaultStyleKey etc.
    }
    ...
    protected override AutomationPeer OnCreateAutomationPeer()
    {
        return new NumericUpDownAutomationPeer(this);
    }
}
```

VB

```
Public Class NumericUpDown
    Inherits RangeBase
    ' other initialization; DefaultStyleKey etc.
       Public Sub New()
       End Sub
       Protected Overrides Function OnCreateAutomationPeer() As
AutomationPeer
              Return New NumericUpDownAutomationPeer(Me)
       End Function
End Class
```

C++/WinRT

```
// NumericUpDown.idl
namespace MyNamespace
{
    runtimeclass NumericUpDown :
Windows.UI.Xaml.Controls.Primitives.RangeBase
    {
        NumericUpDown();
        Int32 MyProperty;
```

```
    }
}

// NumericUpDown.h
...
struct NumericUpDown : NumericUpDownT<NumericUpDown>
{
    ...
    Windows::UI::Xaml::Automation::Peers::AutomationPeer
OnCreateAutomationPeer()
    {
        return
winrt::make<MyNamespace::implementation::NumericUpDownAutomationPeer>
(*this);
    }
};
```

C++

```
//.h
public ref class NumericUpDown sealed :
Windows::UI::Xaml::Controls::Primitives::RangeBase
{
// other initialization not shown
protected:
    virtual AutomationPeer^ OnCreateAutomationPeer() override
    {
         return ref new NumericUpDownAutomationPeer(this);
    }
};
```

> **Note**
>
> The OnCreateAutomationPeer implementation should do nothing more than initialize a new instance of your custom automation peer, passing the calling control as owner, and return that instance. Do not attempt additional logic in this method. In particular, any logic that could potentially lead to destruction of the AutomationPeer within the same call may result in unexpected runtime behavior.

In typical implementations of OnCreateAutomationPeer, the *owner* is specified as **this** or **Me** because the method override is in the same scope as the rest of the control class definition.

The actual peer class definition can be done in the same code file as the control or in a separate code file. The peer definitions all exist in the Windows.UI.Xaml.Automation.Peers namespace that is a separate namespace from the controls that they provide peers for. You can choose to declare your peers in separate

namespaces also, as long as you reference the necessary namespaces for the OnCreateAutomationPeer method call.

Choosing the correct peer base class

Make sure that your AutomationPeer is derived from a base class that gives you the best match for the existing peer logic of the control class you are deriving from. In the case of the previous example, because `NumericUpDown` derives from RangeBase, there is a RangeBaseAutomationPeer class available that you should base your peer on. By using the closest matching peer class in parallel to how you derive the control itself, you can avoid overriding at least some of the IRangeValueProvider functionality because the base peer class already implements it.

The base Control class does not have a corresponding peer class. If you need a peer class to correspond to a custom control that derives from **Control**, derive the custom peer class from FrameworkElementAutomationPeer.

If you derive from ContentControl directly, that class has no default automation peer behavior because there is no OnCreateAutomationPeer implementation that references a peer class. So make sure either to implement **OnCreateAutomationPeer** to use your own peer, or to use FrameworkElementAutomationPeer as the peer if that level of accessibility support is adequate for your control.

> ⓘ **Note**
>
> You don't typically derive from AutomationPeer rather than FrameworkElementAutomationPeer. If you did derive directly from **AutomationPeer** you'll need to duplicate a lot of basic accessibility support that would otherwise come from **FrameworkElementAutomationPeer**.

Initialization of a custom peer class

The automation peer should define a type-safe constructor that uses an instance of the owner control for base initialization. In the next example, the implementation passes the *owner* value on to the RangeBaseAutomationPeer base, and ultimately it is the FrameworkElementAutomationPeer that actually uses *owner* to set FrameworkElementAutomationPeer.Owner.

```
C#
```

```
public NumericUpDownAutomationPeer(NumericUpDown owner): base(owner)
{}
```

VB

```
Public Sub New(owner As NumericUpDown)
    MyBase.New(owner)
End Sub
```

C++/WinRT

```
// NumericUpDownAutomationPeer.idl
import "NumericUpDown.idl";
namespace MyNamespace
{
    runtimeclass NumericUpDownAutomationPeer :
Windows.UI.Xaml.Automation.Peers.AutomationPeer
    {
        NumericUpDownAutomationPeer(NumericUpDown owner);
        Int32 MyProperty;
    }
}

// NumericUpDownAutomationPeer.h
...
struct NumericUpDownAutomationPeer :
NumericUpDownAutomationPeerT<NumericUpDownAutomationPeer>
{
    ...
    NumericUpDownAutomationPeer(MyNamespace::NumericUpDown const& owner);
};
```

C++

```
//.h
public ref class NumericUpDownAutomationPeer sealed :
Windows::UI::Xaml::Automation::Peers::RangeBaseAutomationPeer
//.cpp
public:    NumericUpDownAutomationPeer(NumericUpDown^ owner);
```

Core methods of AutomationPeer

For UWP infrastructure reasons, the overridable methods of an automation peer are part of a pair of methods: the public access method that the UI Automation provider uses as a forwarding point for UI Automation clients, and the protected "Core" customization method that a UWP class can override to influence the behavior. The method pair is

wired together by default in such a way that the call to the access method always invokes the parallel "Core" method that has the provider implementation, or as a fallback, invokes a default implementation from the base classes.

When implementing a peer for a custom control, override any of the "Core" methods from the base automation peer class where you want to expose behavior that is unique to your custom control. UI Automation code gets information about your control by calling public methods of the peer class. To provide information about your control, override each method with a name that ends with "Core" when your control implementation and design creates accessibility scenarios or other UI Automation scenarios that differ from what's supported by the base automation peer class.

At a minimum, whenever you define a new peer class, implement the GetClassNameCore method, as shown in the next example.

C#

```
protected override string GetClassNameCore()
{
    return "NumericUpDown";
}
```

> ⓘ Note
>
> You might want to store the strings as constants rather than directly in the method body, but that is up to you. For GetClassNameCore, you won't need to localize this string. The **LocalizedControlType** property is used any time a localized string is needed by a UI Automation client, not **ClassName**.

GetAutomationControlType

Some assistive technologies use the GetAutomationControlType value directly when reporting characteristics of the items in a UI Automation tree, as additional information beyond the UI Automation **Name**. If your control is significantly different from the control you are deriving from and you want to report a different control type from what is reported by the base peer class used by the control, you must implement a peer and override GetAutomationControlTypeCore in your peer implementation. This is particularly important if you derive from a generalized base class such as ItemsControl or ContentControl, where the base peer doesn't provide precise information about control type.

Your implementation of GetAutomationControlTypeCore describes your control by returning an AutomationControlType value. Although you can return **AutomationControlType.Custom**, you should return one of the more specific control types if it accurately describes your control's main scenarios. Here's an example.

```
C#

protected override AutomationControlType GetAutomationControlTypeCore()
{
    return AutomationControlType.Spinner;
}
```

> ⓘ Note
>
> Unless you specify AutomationControlType.Custom, you don't have to implement GetLocalizedControlTypeCore to provide a **LocalizedControlType** property value to clients. UI Automation common infrastructure provides translated strings for every possible **AutomationControlType** value other than **AutomationControlType.Custom**.

GetPattern and GetPatternCore

A peer's implementation of GetPatternCore returns the object that supports the pattern that is requested in the input parameter. Specifically, a UI Automation client calls a method that is forwarded to the provider's GetPattern method, and specifies a PatternInterface enumeration value that names the requested pattern. Your override of **GetPatternCore** should return the object that implements the specified pattern. That object is the peer itself, because the peer should implement the corresponding pattern interface any time that it reports that it supports a pattern. If your peer does not have a custom implementation of a pattern, but you know that the peer's base does implement the pattern, you can call the base type's implementation of **GetPatternCore** from your **GetPatternCore**. A peer's **GetPatternCore** should return **null** if a pattern is not supported by the peer. However, instead of returning **null** directly from your implementation, you would usually rely on the call to the base implementation to return **null** for any unsupported pattern.

When a pattern is supported, the GetPatternCore implementation can return **this** or **Me**. The expectation is that the UI Automation client will cast the GetPattern return value to the requested pattern interface whenever it is not **null**.

If a peer class inherits from another peer, and all necessary support and pattern reporting is already handled by the base class, implementing **GetPatternCore** isn't necessary. For example, if you are implementing a range control that derives from **RangeBase**, and your peer derives from **RangeBaseAutomationPeer**, that peer returns itself for **PatternInterface.RangeValue** and has working implementations of the **IRangeValueProvider** interface that supports the pattern.

Although it is not the literal code, this example approximates the implementation of **GetPatternCore** already present in **RangeBaseAutomationPeer**.

C#

```
protected override object GetPatternCore(PatternInterface patternInterface)
{
    if (patternInterface == PatternInterface.RangeValue)
    {
        return this;
    }
    return base.GetPatternCore(patternInterface);
}
```

If you are implementing a peer where you don't have all the support you need from a base peer class, or you want to change or add to the set of base-inherited patterns that your peer can support, then you should override **GetPatternCore** to enable UI Automation clients to use the patterns.

For a list of the provider patterns that are available in the UWP implementation of UI Automation support, see **Windows.UI.Xaml.Automation.Provider**. Each such pattern has a corresponding value of the **PatternInterface** enumeration, which is how UI Automation clients request the pattern in a **GetPattern** call.

A peer can report that it supports more than one pattern. If so, the override should include return path logic for each supported **PatternInterface** value and return the peer in each matching case. It is expected that the caller will request only one interface at a time, and it is up to the caller to cast to the expected interface.

Here's an example of a **GetPatternCore** override for a custom peer. It reports the support for two patterns, **IRangeValueProvider** and **IToggleProvider**. The control here is a media display control that can display as full-screen (the toggle mode) and that has a progress bar within which users can select a position (the range control). This code came from the XAML accessibility sample.

C#

```
protected override object GetPatternCore(PatternInterface patternInterface)
{
    if (patternInterface == PatternInterface.RangeValue)
    {
        return this;
    }
    else if (patternInterface == PatternInterface.Toggle)
    {
        return this;
    }
    return null;
}
```

Forwarding patterns from sub-elements

A **GetPatternCore** method implementation can also specify a sub-element or part as a pattern provider for its host. This example mimics how **ItemsControl** transfers scroll-pattern handling to the peer of its internal **ScrollViewer** control. To specify a sub-element for pattern handling, this code gets the sub-element object, creates a peer for the sub-element by using the **FrameworkElementAutomationPeer.CreatePeerForElement** method, and returns the new peer.

C#

```
protected override object GetPatternCore(PatternInterface patternInterface)
{
    if (patternInterface == PatternInterface.Scroll)
    {
        ItemsControl owner = (ItemsControl) base.Owner;
        UIElement itemsHost = owner.ItemsHost;
        ScrollViewer element = null;
        while (itemsHost != owner)
        {
            itemsHost = VisualTreeHelper.GetParent(itemsHost) as UIElement;
            element = itemsHost as ScrollViewer;
            if (element != null)
            {
                break;
            }
        }
        if (element != null)
        {
            AutomationPeer peer =
FrameworkElementAutomationPeer.CreatePeerForElement(element);
            if ((peer != null) && (peer is IScrollProvider))
            {
                return (IScrollProvider) peer;
            }
```

```
            }
        }
        return base.GetPatternCore(patternInterface);
    }
```

Other Core methods

Your control may need to support keyboard equivalents for primary scenarios; for more info about why this might be necessary, see Keyboard accessibility. Implementing the key support is necessarily part of the control code and not the peer code because that is part of a control's logic, but your peer class should override the **GetAcceleratorKeyCore** and **GetAccessKeyCore** methods to report to UI Automation clients which keys are used. Consider that the strings that report key information might need to be localized, and should therefore come from resources, not hard-coded strings.

If you are providing a peer for a class that supports a collection, it's best to derive from both functional classes and peer classes that already have that kind of collection support. If you can't do so, peers for controls that maintain child collections may have to override the collection-related peer method **GetChildrenCore** to properly report the parent-child relationships to the UI Automation tree.

Implement the **IsContentElementCore** and **IsControlElementCore** methods to indicate whether your control contains data content or fulfills an interactive role in the user interface (or both). By default, both methods return **true**. These settings improve the usability of assistive technologies such as screen readers, which may use these methods to filter the automation tree. If your **GetPatternCore** method transfers pattern handling to a sub-element peer, the sub-element peer's **IsControlElementCore** method can return **false** to hide the sub-element peer from the automation tree.

Some controls may support labeling scenarios, where a text label part supplies information for a non-text part, or a control is intended to be in a known labeling relationship with another control in the UI. If it's possible to provide a useful class-based behavior, you can override **GetLabeledByCore** to provide this behavior.

GetBoundingRectangleCore and **GetClickablePointCore** are used mainly for automated testing scenarios. If you want to support automated testing for your control, you might want to override these methods. This might be desired for range-type controls, where you can't suggest just a single point because where the user clicks in coordinate space has a different effect on a range. For example, the default **ScrollBar** automation peer overrides **GetClickablePointCore** to return a "not a number" **Point** value.

GetLiveSettingCore influences the control default for the **LiveSetting** value for UI Automation. You might want to override this if you want your control to return a value

other than AutomationLiveSetting.Off. For more info on what **LiveSetting** represents, see AutomationProperties.LiveSetting.

You might override GetOrientationCore if your control has a settable orientation property that can map to AutomationOrientation. The ScrollBarAutomationPeer and SliderAutomationPeer classes do this.

Base implementation in FrameworkElementAutomationPeer

The base implementation of FrameworkElementAutomationPeer provides some UI Automation information that can be interpreted from various layout and behavior properties that are defined at the framework level.

- GetBoundingRectangleCore: Returns a Rect structure based on the known layout characteristics. Returns a 0-value **Rect** if IsOffscreen is **true**.
- GetClickablePointCore: Returns a Point structure based on the known layout characteristics, as long as there is a nonzero **BoundingRectangle**.
- GetNameCore: More extensive behavior than can be summarized here; see GetNameCore. Basically, it attempts a string conversion on any known content of a ContentControl or related classes that have content. Also, if there is a value for LabeledBy, that item's **Name** value is used as the **Name**.
- HasKeyboardFocusCore: Evaluated based on the owner's FocusState and IsEnabled properties. Elements that aren't controls always return **false**.
- IsEnabledCore: Evaluated based on the owner's IsEnabled property if it is a Control. Elements that aren't controls always return **true**. This doesn't mean that the owner is enabled in the conventional interaction sense; it means that the peer is enabled despite the owner not having an **IsEnabled** property.
- IsKeyboardFocusableCore: Returns **true** if owner is a Control; otherwise it is **false**.
- IsOffscreenCore: A Visibility of Collapsed on the owner element or any of its parents equates to a **true** value for IsOffscreen. Exception: a Popup object can be visible even if its owner's parents are not.
- SetFocusCore: Calls Focus.
- GetParent: Calls FrameworkElement.Parent from the owner, and looks up the appropriate peer. This isn't an override pair with a "Core" method, so you can't change this behavior.

> ⓘ **Note**
>
> Default UWP peers implement a behavior by using internal native code that implements the UWP, not necessarily by using actual UWP code. You won't be able

to see the code or logic of the implementation through common language runtime (CLR) reflection or other techniques. You also won't see distinct reference pages for subclass-specific overrides of base peer behavior. For example, there might be additional behavior for GetNameCore of a TextBoxAutomationPeer, which won't be described on the **AutomationPeer.GetNameCore** reference page, and there is no reference page for **TextBoxAutomationPeer.GetNameCore**. There isn't even a **TextBoxAutomationPeer.GetNameCore** reference page. Instead, read the reference topic for the most immediate peer class, and look for implementation notes in the Remarks section.

Peers and AutomationProperties

Your automation peer should provide appropriate default values for your control's accessibility-related information. Note that any app code that uses the control can override some of that behavior by including **AutomationProperties** attached-property values on control instances. Callers can do this either for the default controls or for custom controls. For example, the following XAML creates a button that has two customized UI Automation properties: `<Button AutomationProperties.Name="Special" AutomationProperties.HelpText="This is a special button."/>`

For more info about **AutomationProperties** attached properties, see Basic accessibility information.

Some of the **AutomationPeer** methods exist because of the general contract of how UI Automation providers are expected to report information, but these methods are not typically implemented in control peers. This is because that info is expected to be provided by **AutomationProperties** values applied to the app code that uses the controls in a specific UI. For example, most apps would define the labeling relationship between two different controls in the UI by applying a **AutomationProperties.LabeledBy** value. However, **LabeledByCore** is implemented in certain peers that represent data or item relationships in a control, such as using a header part to label a data-field part, labeling items with their containers, or similar scenarios.

Implementing patterns

Let's look at how to write a peer for a control that implements an expand-collapse behavior by implementing the control pattern interface for expand-collapse. The peer should enable the accessibility for the expand-collapse behavior by returning itself whenever **GetPattern** is called with a value of **PatternInterface.ExpandCollapse**. The

peer should then inherit the provider interface for that pattern (**IExpandCollapseProvider**) and provide implementations for each of the members of that provider interface. In this case the interface has three members to override: **Expand**, **Collapse**, **ExpandCollapseState**.

It's helpful to plan ahead for accessibility in the API design of the class itself. Whenever you have a behavior that is potentially requested either as a result of typical interactions with a user who is working in the UI or through an automation provider pattern, provide a single method that either the UI response or the automation pattern can call. For example, if your control has button parts that have wired event handlers that can expand or collapse the control, and has keyboard equivalents for those actions, have these event handlers call the same method that you call from within the body of the **Expand** or **Collapse** implementations for **IExpandCollapseProvider** in the peer. Using a common logic method can also be a useful way to make sure that your control's visual states are updated to show logical state in a uniform way, regardless of how the behavior was invoked.

A typical implementation is that the provider APIs first call **Owner** for access to the control instance at run time. Then the necessary behavior methods can be called on that object.

C#

```
public class IndexCardAutomationPeer : FrameworkElementAutomationPeer,
IExpandCollapseProvider {
    private IndexCard ownerIndexCard;
    public IndexCardAutomationPeer(IndexCard owner) : base(owner)
    {
         ownerIndexCard = owner;
    }
}
```

An alternate implementation is that the control itself can reference its peer. This is a common pattern if you are raising automation events from the control, because the **RaiseAutomationEvent** method is a peer method.

UI Automation events

UI Automation events fall into the following categories.

Expand table

Event	Description
Property change	Fires when a property on a UI Automation element or control pattern changes. For example, if a client needs to monitor an app's check box control, it can register to listen for a property change event on the ToggleState property. When the check box control is checked or unchecked, the provider fires the event and the client can act as necessary.
Element action	Fires when a change in the UI results from user or programmatic activity; for example, when a button is clicked or invoked through the **Invoke** pattern.
Structure change	Fires when the structure of the UI Automation tree changes. The structure changes when new UI items become visible, hidden, or removed on the desktop.
Global change	Fires when actions of global interest to the client occur, such as when the focus shifts from one element to another, or when a child window closes. Some events do not necessarily mean that the state of the UI has changed. For example, if the user tabs to a text-entry field and then clicks a button to update the field, a TextChanged event fires even if the user did not actually change the text. When processing an event, it may be necessary for a client application to check whether anything has actually changed before taking action.

AutomationEvents identifiers

UI Automation events are identified by AutomationEvents values. The values of the enumeration uniquely identify the kind of event.

Raising events

UI Automation clients can subscribe to automation events. In the automation peer model, peers for custom controls must report changes to control state that are relevant to accessibility by calling the RaiseAutomationEvent method. Similarly, when a key UI Automation property value changes, custom control peers should call the RaisePropertyChangedEvent method.

The next code example shows how to get the peer object from within the control definition code and call a method to fire an event from that peer. As an optimization, the code determines whether there are any listeners for this event type. Firing the event and creating the peer object only when there are listeners avoids unnecessary overhead and helps the control remain responsive.

C#

```
if (AutomationPeer.ListenerExists(AutomationEvents.PropertyChanged))
{
    NumericUpDownAutomationPeer peer =
```

```
        FrameworkElementAutomationPeer.FromElement(nudCtrl) as
NumericUpDownAutomationPeer;
    if (peer != null)
    {
        peer.RaisePropertyChangedEvent(
            RangeValuePatternIdentifiers.ValueProperty,
            (double)oldValue,
            (double)newValue);
    }
}
```

Peer navigation

After locating an automation peer, a UI Automation client can navigate the peer structure of an app by calling the peer object's **GetChildren** and **GetParent** methods. Navigation among UI elements within a control is supported by the peer's implementation of the **GetChildrenCore** method. The UI Automation system calls this method to build up a tree of sub-elements contained within a control; for example, list items in a list box. The default **GetChildrenCore** method in **FrameworkElementAutomationPeer** traverses the visual tree of elements to build the tree of automation peers. Custom controls can override this method to expose a different representation of child elements to automation clients, returning the automation peers of elements that convey information or allow user interaction.

Native automation support for text patterns

Some of the default UWP app automation peers provide control pattern support for the text pattern (**PatternInterface.Text**). But they provide this support through native methods, and the peers involved won't note the **ITextProvider** interface in the (managed) inheritance. Still, if a managed or non-managed UI Automation client queries the peer for patterns, it will report support for the text pattern, and provide behavior for parts of the pattern when client APIs are called.

If you intend to derive from one of the UWP app text controls and also create a custom peer that derives from one of the text-related peers, check the Remarks sections for the peer to learn more about any native-level support for patterns. You can access the native base behavior in your custom peer if you call the base implementation from your managed provider interface implementations, but it's difficult to modify what the base implementation does because the native interfaces on both the peer and its owner control aren't exposed. Generally you should either use the base implementations as-is (call base only) or completely replace the functionality with your own managed code and don't call the base implementation. The latter is an advanced scenario, you'll need

good familiarity with the text services framework being used by your control in order to support the accessibility requirements when using that framework.

AutomationProperties.AccessibilityView

In addition to providing a custom peer, you can also adjust the tree view representation for any control instance, by setting **AutomationProperties.AccessibilityView** in XAML. This isn't implemented as part of a peer class, but we'll mention it here because it's germane to overall accessibility support either for custom controls or for templates you customize.

The main scenario for using **AutomationProperties.AccessibilityView** is to deliberately omit certain controls in a template from the UI Automation views, because they don't meaningfully contribute to the accessibility view of the entire control. To prevent this, set **AutomationProperties.AccessibilityView** to "Raw".

Throwing exceptions from automation peers

The APIs that you are implementing for your automation peer support are permitted to throw exceptions. It's expected any UI Automation clients that are listening are robust enough to continue on after most exceptions are thrown. In all likelihood that listener is looking at an all-up automation tree that includes apps other than your own, and it's an unacceptable client design to bring down the entire client just because one area of the tree threw a peer-based exception when the client called its APIs.

For parameters that are passed in to your peer, it's acceptable to validate the input, and for example throw **ArgumentNullException** if it was passed **null** and that's not a valid value for your implementation. However, if there are subsequent operations performed by your peer, remember that the peer's interactions with the hosting control have something of an asynchronous character to them. Anything a peer does won't necessarily block the UI thread in the control (and it probably shouldn't). So you could have situations where an object was available or had certain properties when the peer was created or when an automation peer method was first called, but in the meantime the control state has changed. For these cases, there are two dedicated exceptions that a provider can throw:

- Throw **ElementNotAvailableException** if you're unable to access either the peer's owner or a related peer element based on the original info your API was passed. For example, you might have a peer that's trying to run its methods but the owner has since been removed from the UI, such as a modal dialog that's been closed. For a non-.NET client, this maps to **UIA_E_ELEMENTNOTAVAILABLE**.

- Throw **ElementNotEnabledException** if there still is an owner, but that owner is in a mode such as **IsEnabled** = **false** that's blocking some of the specific programmatic changes that your peer is trying to accomplish. For a non-.NET client, this maps to **UIA_E_ELEMENTNOTENABLED**.

Beyond this, peers should be relatively conservative regarding exceptions that they throw from their peer support. Most clients won't be able to handle exceptions from peers and turn these into actionable choices that their users can make when interacting with the client. So sometimes a no-op, and catching exceptions without rethrowing within your peer implementations, is a better strategy than is throwing exceptions every time something the peer tries to do doesn't work. Consider also that most UI Automation clients aren't written in managed code. Most are written in COM and are just checking for **S_OK** in an **HRESULT** whenever they call a UI Automation client method that ends up accessing your peer.

Control patterns and interfaces

Article • 01/04/2023

Lists the Microsoft UI Automation control patterns, the classes that clients use to access them, and the interfaces providers use to implement them.

The table in this topic describes the Microsoft UI Automation control patterns. The table also lists the classes used by UI Automation clients to access the control patterns and the interfaces used by UI Automation providers to implement them. The **Control pattern** column shows the pattern name from the UI Automation client perspective, as a constant value listed in **Control Pattern Availability Property Identifiers**. From the UI Automation provider perspective, each of these patterns is a **PatternInterface** constant name. The **Class provider interface** column shows the name of the interface that providers implement to provide this pattern for a custom XAML control.

For more info about how to implement custom automation peers that expose control patterns and implement the interfaces, see Custom automation peers.

When you implement a control pattern, you should also consult the UI Automation provider documentation that explains some of the expectations that clients will have of a control pattern regardless of which UI framework is used to implement it. Some of the info listed in the general UI Automation provider documentation will influence how you implement your peers and correctly support that pattern. See Implementing UI Automation Control Patterns, and view the page that documents the pattern you intend to implement.

Control pattern	Class provider interface	Description
Annotation	IAnnotationProvider	Used to expose the properties of an annotation in a document.
Dock	IDockProvider	Used for controls that can be docked in a docking container. For example, toolbars or tool palettes.
Drag	IDragProvider	Used to support draggable controls, or controls with draggable items.
DropTarget	IDropTargetProvider	Used to support controls that can be the target of a drag-and-drop operation.
ExpandCollapse	IExpandCollapseProvider	Used to support controls that visually expand to display more content and collapse to hide content.

Control pattern	Class provider interface	Description
Grid	IGridProvider	Used for controls that support grid functionality such as sizing and moving to a specified cell. Note that Grid itself does not implement this pattern because it provides layout but is not a control.
GridItem	IGridItemProvider	Used for controls that have cells within grids.
Invoke	IInvokeProvider	Used for controls that can be invoked, such as a Button.
ItemContainer	IItemContainerProvider	Enables applications to find an element in a container, such as a virtualized list.
MultipleView	IMultipleViewProvider	Used for controls that can switch between multiple representations of the same set of information, data, or children.
ObjectModel	IObjectModelProvider	Used to expose a pointer to the underlying object model of a document.
RangeValue	IRangeValueProvider	Used for controls that have a range of values that can be applied to the control. For example, a spinner control containing years might have a range of 1900 to the current year, while another spinner control presenting months would have a range of 1 to 12.
Scroll	IScrollProvider	Used for controls that can scroll. For example, a control that has scroll bars that are active when there is more information than can be displayed in the viewable area of the control.
ScrollItem	IScrollItemProvider	Used for controls that have individual items in a list that scrolls. For example, a list control that has individual items in the scroll list, such as a combo box control.
Selection	ISelectionProvider	Used for selection container controls. For example, ListBox and ComboBox.
SelectionItem	ISelectionItemProvider	Used for individual items in selection container controls, such as list boxes and combo boxes.
Spreadsheet	ISpreadsheetProvider	Used to expose the contents of a spreadsheet or other grid-based document.

Control pattern	Class provider interface	Description
SpreadsheetItem	ISpreadsheetItemProvider	Used to expose the properties of a cell in a spreadsheet or other grid-based document.
Styles	IStylesProvider	Used to describe a UI element that has a specific style, fill color, fill pattern, or shape.
SynchronizedInput	ISynchronizedInputProvider	Enables UI Automation client apps to direct the mouse or keyboard input to a specific UI element.
Table	ITableProvider	Used for controls that have a grid as well as header information. For example, a tabular calendar control.
TableItem	ITableItemProvider	Used for items in a table.
Text	ITextProvider	Used for edit controls and documents that expose textual information. See also ITextRangeProvider and ITextProvider2.
TextChild	ITextChildProvider	Used to access an element's nearest ancestor that supports the **Text** control pattern.
TextEdit	No managed class available	Provides access to a control that modifies text, for example a control that performs auto-correction or enables input composition through an Input Method Editor (IME).
TextRange	ITextRangeProvider	Provides access to a span of continuous text in a text container that implements ITextProvider. See also ITextRangeProvider2.
Toggle	IToggleProvider	Used for controls where the state can be toggled. For example, CheckBox and menu items that can be checked.
Transform	ITransformProvider	Used for controls that can be resized, moved, and rotated. Typical uses for the Transform control pattern are in designers, forms, graphical editors, and drawing applications.
Value	IValueProvider	Allows clients to get or set a value on controls that do not support a range of values.

Control pattern	Class provider interface	Description
VirtualizedItem	IVirtualizedItemProvider	Exposes items inside containers that are virtualized and need to be made fully accessible as UI Automation elements.
Window	IWindowProvider	Exposes information specific to windows, a fundamental concept to the Microsoft Windows operating system. Examples of controls that are windows are child windows and dialogs.

> **Note**
>
> You won't necessarily find implementations of all these patterns in existing XAML controls. Some of the patterns have interfaces solely to support parity with the general UI Automation framework definition of patterns, and to support automation peer scenarios that will require a purely custom implementation to support that pattern.

> **Note**
>
> Windows Phone Store apps do not support all the UI Automation control patterns listed here. **Annotation**, **Dock**, **Drag**, **DropTarget**, **ObjectModel** are some of the unsupported patterns.

Guidelines for app settings

Article • 06/24/2021

App settings are the user-customizable portions of your Windows app accessed through an app settings page. For example, a news reader app might let the user specify which news sources to display or how many columns to display on the screen, while a weather app could let the user choose between Celsius and Fahrenheit. This article provides recommendations and best practices for creating and displaying app settings.

When to provide a settings page

Here are examples of app options that belong in an app settings page:

- Configuration options that affect the behavior of the app and don't require frequent readjustment, like choosing between Celsius or Fahrenheit as default units for temperature in a weather app, changing account settings for a mail app, settings for notifications, or accessibility options.
- Options that depend on the user's preferences, like music, sound effects, or color themes.
- App information that isn't accessed very often, such as privacy policy, help, app version, or copyright info.

Commands that are part of the typical app workflow (for example, changing the brush size in an art app) shouldn't be in a settings page. To learn more about command placement, see Command design basics.

General recommendations

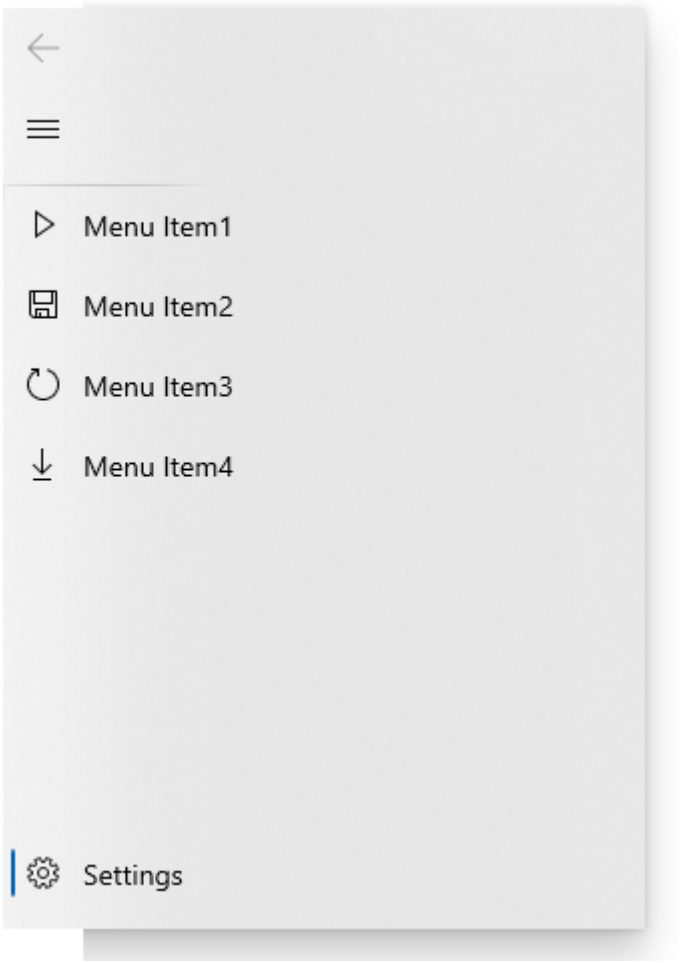
- Keep settings pages simple and make use of binary (on/off) controls. A toggle switch is usually the best control for a binary setting.
- For settings that let users choose one item from a set of up to 5 mutually exclusive, related options, use radio buttons.
- Create an entry point for all app settings in your app setting's page.
- Keep your settings simple. Define smart defaults and keep the number of settings to a minimum.
- When a user changes a setting, the app should immediately reflect the change.
- Don't include commands that are part of the common app workflow.

Entry point

The way that users get to your app settings page should be based on your app's layout.

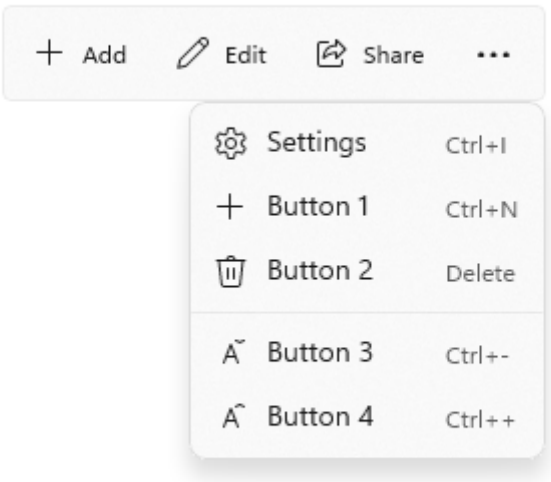
Navigation pane

For a nav pane layout, app settings should be the last item in the list of navigational choices and be pinned to the bottom:



Command bar

If you're using a command bar or tool bar, place the settings entry point as one of the last items in the "More" overflow menu. If greater discoverability for the settings entry point is important for your app, place the entry point directly on the command bar and not within the overflow.



Hub

If you're using a hub layout, the entry point for app settings should be placed inside the "More" overflow menu of a command bar.

Tabs/pivots

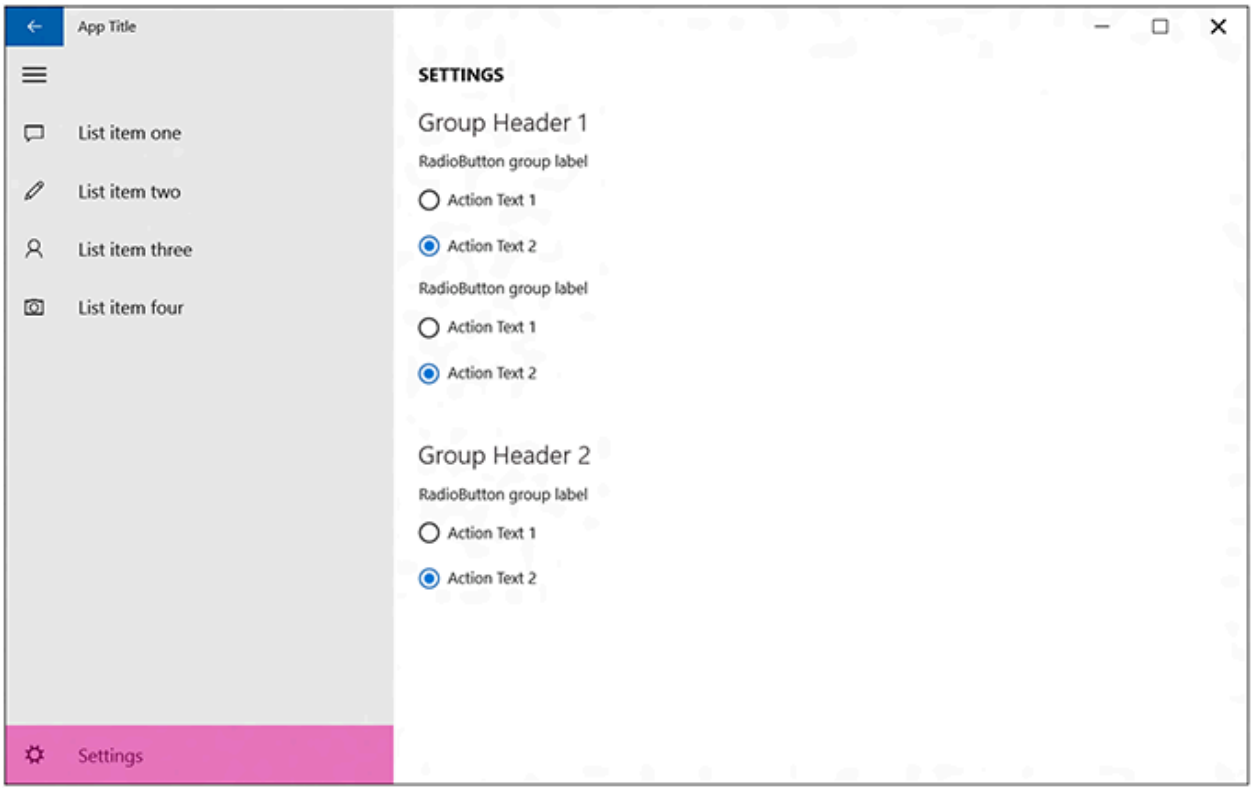
For a tabs or pivots layout, we don't recommend placing the app settings entry point as one of the top items within the navigation. Instead, the entry point for app settings should be placed inside the "More" overflow menu of a command bar.

List-details

Instead of burying the app settings entry point deeply within a list-details pane, make it the last pinned item on the top level of the list pane.

Layout

The app settings window should open full-screen and fill the whole window. If your app settings menu has up to four top-level groups, those groups should cascade down one column.

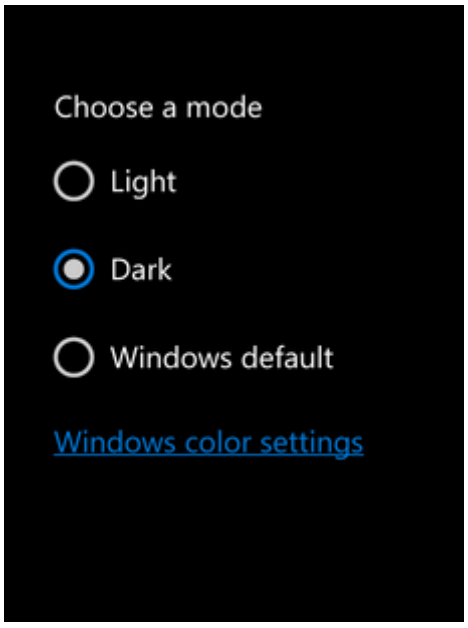


"Color mode" settings

If your app allows users to choose the app's color mode, present these options using radio buttons or a combo box with the header "Choose an app mode". The options should read

- Light
- Dark
- Windows default

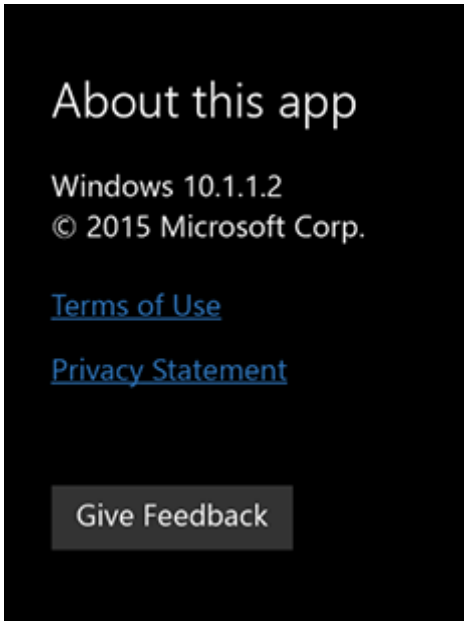
We also recommend adding a hyperlink to the Colors page of the Windows Settings app where users can access and modify the current default app mode. Use the string "Windows color settings" for the hyperlink text and `ms-settings:colors` for the URI.



About section and Feedback button

We recommend placing "About this App" section in your app either as a dedicated page or in its own section. If you want a "Send Feedback" button, place that toward the bottom of the "About this App" page.

Under a "Legal" subheader, place any "Terms of Use" and "Privacy Statement" (should be hyperlink buttons with wrapping text) as well as additional legal information, such as copyright.



Recommended page content

Once you have a list of items that you want to include in your app settings page, consider these guidelines:

- Group similar or related settings under one settings label.
- Try to keep the total number of settings to a maximum of four or five.
- Display the same settings regardless of the app context. If some settings aren't relevant in a certain context, disable those in the app settings flyout.
- Use descriptive, one-word labels for settings. For example, name the setting "Accounts" instead of "Account settings" for account-related settings. If you only want one option for your settings and the settings don't lend themselves to a descriptive label, use "Options" or "Defaults."
- If a setting directly links to the web instead of to a flyout, let the user know this with a visual clue, such as "Help (online)" or "Web forums" styled as a hyperlink. Consider grouping multiple links to the web into a flyout with a single setting. For example, an "About" setting could open a flyout with links to your terms of use, privacy policy, and app support.
- Combine less-used settings into a single entry so that more common settings can each have their own entry. Put content or links that only contain information in an "About" setting.
- Don't duplicate the functionality in the "Permissions" pane. Windows provides this pane by default and you can't modify it.
- Add settings content to Settings flyouts
- Present content from top to bottom in a single column, scrollable if necessary. Limit scrolling to a maximum of twice the screen height.
- Use the following controls for app settings:
  - Toggle switches: To let users set values on or off.
  - Radio buttons: To let users choose one item from a set of up to 5 mutually exclusive, related options.
  - Text input box: To let users enter text. Use the type of text input box that corresponds to the type of text you're getting from the user, such as an email or password.
  - Hyperlinks: To take the user to another page within the app or to an external website. When a user clicks a hyperlink, the Settings flyout will be dismissed.
  - Buttons: To let users initiate an immediate action without dismissing the current Settings flyout.
- Add a descriptive message if one of the controls is disabled. Place this message above the disabled control.

- Animate content and controls as a single block after the Settings flyout and header have animated. Animate content using the **enterPage** or **EntranceThemeTransition** animations with a 100px left offset.
- Use section headers, paragraphs, and labels to aid organize and clarify content, if necessary.
- If you need to repeat settings, use an additional level of UI or an expand/collapse model, but avoid hierarchies deeper than two levels. For example, a weather app that provides per-city settings could list the cities and let the user tap on the city to either open a new flyout or expand to show the settings options.
- If loading controls or web content takes time, use an indeterminate progress control to indicate to users that info is loading. For more info, see Guidelines for progress controls.
- Don't use buttons for navigation or to commit changes. Use hyperlinks to navigate to other pages, and instead of using a button to commit changes, automatically save changes to app settings when a user dismisses the Settings flyout.

Store and retrieve settings and other app data

Article • 06/16/2022

App data is mutable data that is created and managed by a specific app. It includes runtime state, app settings, user preferences, reference content (such as the dictionary definitions in a dictionary app), and other settings. App data is different from *user data*, data that the user creates and manages when using an app. User data includes document or media files, email or communication transcripts, or database records holding content created by the user. User data may be useful or meaningful to more than one app. Often, this is data that the user wants to manipulate or transmit as an entity independent of the app itself, such as a document.

Important note about app data: The lifetime of the app data is tied to the lifetime of the app. If the app is removed, all of the app data will be lost as a consequence. Don't use app data to store user data or anything that users might perceive as valuable and irreplaceable. We recommend that the user's libraries and Microsoft OneDrive be used to store this sort of information. App data is ideal for storing app-specific user preferences, settings, and favorites.

Types of app data

There are two types of app data: settings and files.

Settings

Use settings to store user preferences and application state info. The app data API enables you to easily create and retrieve settings (we'll show you some examples later in this article).

Here are data types you can use for app settings:

- **UInt8**, **Int16**, **UInt16**, **Int32**, **UInt32**, **Int64**, **UInt64**, **Single**, **Double**
- **Boolean**
- **Char16**, **String**
- DateTime, TimeSpan
  - For C#/.NET, use: System.DateTimeOffset, System.TimeSpan
- **GUID**, Point, Size, Rect
- ApplicationDataCompositeValue: A set of related app settings that must be serialized and deserialized atomically. Use composite settings to easily handle

atomic updates of interdependent settings. The system ensures the integrity of composite settings during concurrent access and roaming. Composite settings are optimized for small amounts of data, and performance can be poor if you use them for large data sets.

Files

Use files to store binary data or to enable your own, customized serialized types.

Storing app data in the app data stores

When an app is installed, the system gives it its own per-user data stores for settings and files. You don't need to know where or how this data exists, because the system is responsible for managing the physical storage, ensuring that the data is kept isolated from other apps and other users. The system also preserves the contents of these data stores when the user installs an update to your app and removes the contents of these data stores completely and cleanly when your app is uninstalled.

Within its app data store, each app has system-defined root directories: one for local files, one for roaming files, and one for temporary files. Your app can add new files and new containers to each of these root directories.

Local app data

Local app data should be used for any information that needs to be preserved between app sessions and is not suitable for roaming app data. Data that is not applicable on other devices should be stored here as well. There is no general size restriction on local data stored. Use the local app data store for data that it does not make sense to roam and for large data sets.

Retrieve the local app data store

Before you can read or write local app data, you must retrieve the local app data store. To retrieve the local app data store, use the **ApplicationData.LocalSettings** property to get the app's local settings as an **ApplicationDataContainer** object. Use the **ApplicationData.LocalFolder** property to get the files in a **StorageFolder** object. Use the **ApplicationData.LocalCacheFolder** property to get the folder in the local app data store where you can save files that are not included in backup and restore.

```
CSharp
```

```
Windows.Storage.ApplicationDataContainer localSettings =
    Windows.Storage.ApplicationData.Current.LocalSettings;
Windows.Storage.StorageFolder localFolder =
    Windows.Storage.ApplicationData.Current.LocalFolder;
```

Create and retrieve a simple local setting

To create or write a setting, use the ApplicationDataContainer.Values property to access the settings in the `localSettings` container we got in the previous step. This example creates a setting named `exampleSetting`.

CSharp

```
// Simple setting

localSettings.Values["exampleSetting"] = "Hello Windows";
```

To retrieve the setting, you use the same ApplicationDataContainer.Values property that you used to create the setting. This example shows how to retrieve the setting we just created.

CSharp

```
// Simple setting
Object value = localSettings.Values["exampleSetting"];
```

Create and retrieve a local composite value

To create or write a composite value, create an ApplicationDataCompositeValue object. This example creates a composite setting named `exampleCompositeSetting` and adds it to the `localSettings` container.

CSharp

```
// Composite setting

Windows.Storage.ApplicationDataCompositeValue composite =
    new Windows.Storage.ApplicationDataCompositeValue();
composite["intVal"] = 1;
composite["strVal"] = "string";

localSettings.Values["exampleCompositeSetting"] = composite;
```

This example shows how to retrieve the composite value we just created.

CSharp

```
// Composite setting

Windows.Storage.ApplicationDataCompositeValue composite =

(Windows.Storage.ApplicationDataCompositeValue)localSettings.Values["example
CompositeSetting"];

if (composite == null)
{
   // No data
}
else
{
   // Access data in composite["intVal"] and composite["strVal"]
}
```

Create and read a local file

To create and update a file in the local app data store, use the file APIs, such as Windows.Storage.StorageFolder.CreateFileAsync and Windows.Storage.FileIO.WriteTextAsync. This example creates a file named `dataFile.txt` in the `localFolder` container and writes the current date and time to the file. The **ReplaceExisting** value from the CreationCollisionOption enumeration indicates to replace the file if it already exists.

C#

```
async void WriteTimestamp()
{
   Windows.Globalization.DateTimeFormatting.DateTimeFormatter formatter =
       new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("longtime");

   StorageFile sampleFile = await
localFolder.CreateFileAsync("dataFile.txt",
       CreationCollisionOption.ReplaceExisting);
   await FileIO.WriteTextAsync(sampleFile,
formatter.Format(DateTimeOffset.Now));
}
```

To open and read a file in the local app data store, use the file APIs, such as Windows.Storage.StorageFolder.GetFileAsync, Windows.Storage.StorageFile.GetFileFromApplicationUriAsync, and

Windows.Storage.FileIO.ReadTextAsync. This example opens the `dataFile.txt` file created in the previous step and reads the date from the file. For details on loading file resources from various locations, see How to load file resources.

C#

```
async void ReadTimestamp()
{
   try
   {
      StorageFile sampleFile = await
localFolder.GetFileAsync("dataFile.txt");
      String timestamp = await FileIO.ReadTextAsync(sampleFile);
      // Data is contained in timestamp
   }
   catch (Exception)
   {
      // Timestamp not found
   }
}
```

Roaming data

> ⚠ **Warning**
>
> Roaming data and settings is no longer supported as of Windows 11. The recommended replacement is Azure App Service. Azure App Service is widely supported, well documented, reliable, and supports cross-platform/cross-ecosystem scenarios such as iOS, Android and web.
>
> The following documentation applies to Windows 10 versions 1909 and lower.

If you use roaming data in your app, your users can easily keep your app's app data in sync across multiple devices. If a user installs your app on multiple devices, the OS keeps the app data in sync, reducing the amount of setup work that the user needs to do for your app on their second device. Roaming also enables your users to continue a task, such as composing a list, right where they left off even on a different device. The OS replicates roaming data to the cloud when it is updated, and synchronizes the data to the other devices on which the app is installed.

The OS limits the size of the app data that each app may roam. See ApplicationData.RoamingStorageQuota. If the app hits this limit, none of the app's app data will be replicated to the cloud until the app's total roamed app data is less than the

limit again. For this reason, it is a best practice to use roaming data only for user preferences, links, and small data files.

Roaming data for an app is available in the cloud as long as it is accessed by the user from some device within the required time interval. If the user does not run an app for longer than this time interval, its roaming data is removed from the cloud. If a user uninstalls an app, its roaming data isn't automatically removed from the cloud, it's preserved. If the user reinstalls the app within the time interval, the roaming data is synchronized from the cloud.

Roaming data do's and don'ts

> See important note about roaming data.

- Use roaming for user preferences and customizations, links, and small data files. For example, use roaming to preserve a user's background color preference across all devices.
- Use roaming to let users continue a task across devices. For example, roam app data like the contents of a drafted email or the most recently viewed page in a reader app.
- Handle the **DataChanged** event by updating app data. This event occurs when app data has just finished syncing from the cloud.
- Roam references to content rather than raw data. For example, roam a URL rather than the content of an online article.
- For important, time critical settings, use the *HighPriority* setting associated with **RoamingSettings**.
- Don't roam app data that is specific to a device. Some info is only pertinent locally, such as a path name to a local file resource. If you do decide to roam local information, make sure that the app can recover if the info isn't valid on the secondary device.
- Don't roam large sets of app data. There's a limit to the amount of app data an app may roam; use **RoamingStorageQuota** property to get this maximum. If an app hits this limit, no data can roam until the size of the app data store no longer exceeds the limit. When you design your app, consider how to put a bound on larger data so as to not exceed the limit. For example, if saving a game state requires 10KB each, the app might only allow the user store up to 10 games.
- Don't use roaming for data that relies on instant syncing. Windows doesn't guarantee an instant sync; roaming could be significantly delayed if a user is offline or on a high latency network. Ensure that your UI doesn't depend on instant syncing.

- Don't use roaming for frequently changing data. For example, if your app tracks frequently changing info, such as the position in a song by second, don't store this as roaming app data. Instead, pick a less frequent representation that still provides a good user experience, like the currently playing song.

Roaming pre-requisites

> See important note about roaming data.

Any user can benefit from roaming app data if they use a Microsoft account to log on to their device. However, users and group policy administrators can switch off roaming app data on a device at any time. If a user chooses not to use a Microsoft account or disables roaming data capabilities, she will still be able to use your app, but app data will be local to each device.

Data stored in the **PasswordVault** will only transition if a user has made a device "trusted". If a device isn't trusted, data secured in this vault will not roam.

Conflict resolution

> See important note about roaming data.

Roaming app data is not intended for simultaneous use on more than one device at a time. If a conflict arises during synchronization because a particular data unit was changed on two devices, the system will always favor the value that was written last. This ensures that the app utilizes the most up-to-date information. If the data unit is a setting composite, conflict resolution will still occur on the level of the setting unit, which means that the composite with the latest change will be synchronized.

When to write data

> See important note about roaming data.

Depending on the expected lifetime of the setting, data should be written at different times. Infrequently or slowly changing app data should be written immediately. However, app data that changes frequently should only be written periodically at regular intervals (such as once every 5 minutes), as well as when the app is suspended. For example, a music app might write the "current song" settings whenever a new song starts to play, however, the actual position in the song should only be written on suspend.

Excessive usage protection

> See important note about roaming data.

The system has various protection mechanisms in place to avoid inappropriate use of resources. If app data does not transition as expected, it is likely that the device has been temporarily restricted. Waiting for some time will usually resolve this situation automatically and no action is required.

Versioning

> See important note about roaming data.

App data can utilize versioning to upgrade from one data structure to another. The version number is different from the app version and can be set at will. Although not enforced, it is highly recommended that you use increasing version numbers, since undesirable complications (including data loss)could occur if you try to transition to a lower data version number that represents newer data.

App data only roams between installed apps with the same version number. For example, devices on version 2 will transition data between each other and devices on version 3 will do the same, but no roaming will occur between a device running version 2 and a device running version 3. If you install a new app that utilized various version numbers on other devices, the newly installed app will sync the app data associated with the highest version number.

Testing and tools

> See important note about roaming data.

Developers can lock their device in order to trigger a synchronization of roaming app data. If it seems that the app data does not transition within a certain time frame, please check the following items and make sure that:

- Your roaming data does not exceed the maximum size (see **RoamingStorageQuota** for details).
- Your files are closed and released properly.
- There are at least two devices running the same version of the app.

Register to receive notification when roaming data changes

> See important note about roaming data.

To use roaming app data, you need to register for roaming data changes and retrieve the roaming data containers so you can read and write settings.

1. Register to receive notification when roaming data changes.

   The **DataChanged** event notifies you when roaming data changes. This example sets `DataChangeHandler` as the handler for roaming data changes.

```
C#
```

```
void InitHandlers()
    {
       Windows.Storage.ApplicationData.Current.DataChanged +=
          new TypedEventHandler<ApplicationData, object>(DataChangeHandler);
    }

    void DataChangeHandler(Windows.Storage.ApplicationData appData, object
o)
    {
       // TODO: Refresh your data
    }
```

2. Get the containers for the app's settings and files.

   Use the **ApplicationData.RoamingSettings** property to get the settings and the **ApplicationData.RoamingFolder** property to get the files.

```
C#
```

```
Windows.Storage.ApplicationDataContainer roamingSettings =
        Windows.Storage.ApplicationData.Current.RoamingSettings;
    Windows.Storage.StorageFolder roamingFolder =
        Windows.Storage.ApplicationData.Current.RoamingFolder;
```

Create and retrieve roaming settings

> See important note about roaming data.

Use the ApplicationDataContainer.Values property to access the settings in the `roamingSettings` container we got in the previous section. This example creates a simple setting named `exampleSetting` and a composite value named `composite`.

C#

```
// Simple setting

roamingSettings.Values["exampleSetting"] = "Hello World";
// High Priority setting, for example, last page position in book reader app
roamingSettings.values["HighPriority"] = "65";

// Composite setting

Windows.Storage.ApplicationDataCompositeValue composite =
    new Windows.Storage.ApplicationDataCompositeValue();
composite["intVal"] = 1;
composite["strVal"] = "string";

roamingSettings.Values["exampleCompositeSetting"] = composite;
```

This example retrieves the settings we just created.

C#

```
// Simple setting

Object value = roamingSettings.Values["exampleSetting"];

// Composite setting

Windows.Storage.ApplicationDataCompositeValue composite =

(Windows.Storage.ApplicationDataCompositeValue)roamingSettings.Values["examp
leCompositeSetting"];

if (composite == null)
{
   // No data
}
else
{
   // Access data in composite["intVal"] and composite["strVal"]
}
```

Create and retrieve roaming files

> See important note about roaming data.

To create and update a file in the roaming app data store, use the file APIs, such as Windows.Storage.StorageFolder.CreateFileAsync and Windows.Storage.FileIO.WriteTextAsync. This example creates a file named `dataFile.txt` in the `roamingFolder` container and writes the current date and time to the file. The **ReplaceExisting** value from the CreationCollisionOption enumeration indicates to replace the file if it already exists.

C#

```
async void WriteTimestamp()
{
   Windows.Globalization.DateTimeFormatting.DateTimeFormatter formatter =
       new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("longtime");

   StorageFile sampleFile = await
roamingFolder.CreateFileAsync("dataFile.txt",
       CreationCollisionOption.ReplaceExisting);
   await FileIO.WriteTextAsync(sampleFile,
formatter.Format(DateTimeOffset.Now));
}
```

To open and read a file in the roaming app data store, use the file APIs, such as Windows.Storage.StorageFolder.GetFileAsync, Windows.Storage.StorageFile.GetFileFromApplicationUriAsync, and Windows.Storage.FileIO.ReadTextAsync. This example opens the `dataFile.txt` file created in the previous section and reads the date from the file. For details on loading file resources from various locations, see How to load file resources.

C#

```
async void ReadTimestamp()
{
   try
   {
      StorageFile sampleFile = await
roamingFolder.GetFileAsync("dataFile.txt");
      String timestamp = await FileIO.ReadTextAsync(sampleFile);
      // Data is contained in timestamp
   }
   catch (Exception)
   {
      // Timestamp not found
   }
}
```

Temporary app data

The temporary app data store works like a cache. Its files do not roam and could be removed at any time. The System Maintenance task can automatically delete data stored at this location at any time. The user can also clear files from the temporary data store using Disk Cleanup. Temporary app data can be used for storing temporary information during an app session. There is no guarantee that this data will persist beyond the end of the app session as the system might reclaim the used space if needed. The location is available via the **temporaryFolder** property.

Retrieve the temporary data container

Use the **ApplicationData.TemporaryFolder** property to get the files. The next steps use the `temporaryFolder` variable from this step.

C#

```
Windows.Storage.StorageFolder temporaryFolder =
ApplicationData.Current.TemporaryFolder;
```

Create and read temporary files

To create and update a file in the temporary app data store, use the file APIs, such as **Windows.Storage.StorageFolder.CreateFileAsync** and **Windows.Storage.FileIO.WriteTextAsync**. This example creates a file named `dataFile.txt` in the `temporaryFolder` container and writes the current date and time to the file. The **ReplaceExisting** value from the **CreationCollisionOption** enumeration indicates to replace the file if it already exists.

C#

```
async void WriteTimestamp()
{
   Windows.Globalization.DateTimeFormatting.DateTimeFormatter formatter =
       new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("longtime");

   StorageFile sampleFile = await
temporaryFolder.CreateFileAsync("dataFile.txt",
       CreateCollisionOption.ReplaceExisting);
   await FileIO.WriteTextAsync(sampleFile,
formatter.Format(DateTimeOffset.Now));
}
```

To open and read a file in the temporary app data store, use the file APIs, such as Windows.Storage.StorageFolder.GetFileAsync, Windows.Storage.StorageFile.GetFileFromApplicationUriAsync, and Windows.Storage.FileIO.ReadTextAsync. This example opens the `dataFile.txt` file created in the previous step and reads the date from the file. For details on loading file resources from various locations, see How to load file resources.

C#

```
async void ReadTimestamp()
{
   try
   {
      StorageFile sampleFile = await
temporaryFolder.GetFileAsync("dataFile.txt");
      String timestamp = await FileIO.ReadTextAsync(sampleFile);
      // Data is contained in timestamp
   }
   catch (Exception)
   {
      // Timestamp not found
   }
}
```

Organize app data with containers

To help you organize your app data settings and files, you create containers (represented by ApplicationDataContainer objects) instead of working directly with directories. You can add containers to the local, roaming, and temporary app data stores. Containers can be nested up to 32 levels deep.

To create a settings container, call the ApplicationDataContainer.CreateContainer method. This example creates a local settings container named `exampleContainer` and adds a setting named `exampleSetting`. The **Always** value from the ApplicationDataCreateDisposition enumeration indicates that the container is created if it doesn't already exist.

C#

```
Windows.Storage.ApplicationDataContainer localSettings =
    Windows.Storage.ApplicationData.Current.LocalSettings;
Windows.Storage.StorageFolder localFolder =
    Windows.Storage.ApplicationData.Current.LocalFolder;

// Setting in a container
Windows.Storage.ApplicationDataContainer container =
```

```
    localSettings.CreateContainer("exampleContainer",
Windows.Storage.ApplicationDataCreateDisposition.Always);

if (localSettings.Containers.ContainsKey("exampleContainer"))
{
    localSettings.Containers["exampleContainer"].Values["exampleSetting"] =
"Hello Windows";
}
```

Delete app settings and containers

To delete a simple setting that your app no longer needs, use the ApplicationDataContainerSettings.Remove method. This example deletes the `exampleSetting` local setting that we created earlier.

C#

```
Windows.Storage.ApplicationDataContainer localSettings =
    Windows.Storage.ApplicationData.Current.LocalSettings;
Windows.Storage.StorageFolder localFolder =
    Windows.Storage.ApplicationData.Current.LocalFolder;

// Delete simple setting

localSettings.Values.Remove("exampleSetting");
```

To delete a composite setting, use the ApplicationDataCompositeValue.Remove method. This example deletes the local `exampleCompositeSetting` composite setting we created in an earlier example.

C#

```
Windows.Storage.ApplicationDataContainer localSettings =
    Windows.Storage.ApplicationData.Current.LocalSettings;
Windows.Storage.StorageFolder localFolder =
    Windows.Storage.ApplicationData.Current.LocalFolder;

// Delete composite setting

localSettings.Values.Remove("exampleCompositeSetting");
```

To delete a container, call the ApplicationDataContainer.DeleteContainer method. This example deletes the local `exampleContainer` settings container we created earlier.

C#

```
Windows.Storage.ApplicationDataContainer localSettings =
    Windows.Storage.ApplicationData.Current.LocalSettings;
Windows.Storage.StorageFolder localFolder =
    Windows.Storage.ApplicationData.Current.LocalFolder;

// Delete container

localSettings.DeleteContainer("exampleContainer");
```

Versioning your app data

You can optionally version the app data for your app. This would enable you to create a future version of your app that changes the format of its app data without causing compatibility problems with the previous version of your app. The app checks the version of the app data in the data store, and if the version is less than the version the app expects, the app should update the app data to the new format and update the version. For more info, see the**Application.Version** property and the **ApplicationData.SetVersionAsync** method.

Globalization and localization

Article • 12/15/2021

Windows is used worldwide by audiences that are diverse in terms of language, region, and culture. Your users speak a variety of different languages and in a variety of different countries and regions. Some users speak more than one language. So, your app runs on configurations that involve many permutations of system settings for language, region, and culture. You can increase the potential market for your app by designing it to be readily adaptable, using *globalization* and *localization*.

For a short video that demonstrates how to prepare your app for the world, see Introduction to globalization and localization.

Globalization is the process of designing and developing your app in such a way that it functions appropriately in different global markets (on systems with different language and culture configurations) without requiring culture-specific changes or customization.

- Take culture into account when manipulating strings, for example don't change the case of strings before comparing them.
- Use calendars that are appropriate for the current culture.
- Use globalization APIs to display data that are formatted appropriately for the country or region, such as numbers, dates, times, and currencies.
- Take into account that different cultures have different rules for collating (sorting) text and other data.

Your code needs to function equally well in any of the cultures that you've determined that your app will support. Ideally, your code will function equally well in the context of *any* language, region, or culture. The most efficient way to globalize your app's functions is to use the concept of cultures/locales. A culture/locale is a set of rules and a set of data that are specific to a given language and geographic area. These rules and data include information about the following.

- Character classification
- Writing system
- Date and time formatting
- Numeric, currency, weight, and measure conventions
- Sorting rules

> **Note**

For a list of supported locale names by Windows operating system version, see the Language tag column of the table in **Appendix A: Product Behavior** in the **Windows Language Code Identifier (LCID) Reference**.

Localizability is the process of preparing a globalized app for localization and/or verifying that the app is ready for localization. Correctly making an app localizable means that the later localization process will not uncover any functional defects in the app. The most essential property of a localizable app is that its executable code has been cleanly separated from the app's localizable resources.

- Strings translated into different languages can vary greatly in length. So, design your UI to accommodate different text lengths and font sizes for labels and text input controls.
- Try to avoid text and/or culturally-sensitive material in images.
- Don't hard-code strings and culture-dependent images in your app's code and markup. Instead, store them as string and image resources so that they can be adapted to different local markets independently of your app's built binaries.
- Pseudo-localize your app to disclose any localizability issues.

Localization is the process of adapting or translating your app's localizable resources to meet the language, cultural, and political requirements of the specific local markets that the app is intended to support. By the time you reach the stage of localizing your app, if your app is localizable then you will not have to modify any logic during this process.

- Translate the string resources and other assets of the app for the new market.
- Modify any culture-dependent images as necessary.
- Files can also vary depending on a user's region, separate from their language. For example, a map may have different borders depending on the user's location, but the labels should follow the user's preferred language.

Most localization teams use special tools to aid the process. For example, by recycling translations of recurring text.

Guidelines for globalization

Article • 06/24/2021

Design and develop your app in such a way that it functions appropriately on systems with different language and culture configurations. Use **Globalization** APIs to format data; and avoid assumptions in your code about language, region, character classification, writing system, date/time formatting, numbers, currencies, weights, and sorting rules.

Expand table

Recommendation	Description
Take culture into account when manipulating and comparing strings.	For example, don't change the case of strings before comparing them. See Recommendations for String Usage.
When collating (sorting) strings and other data, don't assume that it's is always done alphabetically.	For languages that don't use Latin script, collation is based on factors such as pronunciation, or number of pen strokes. Even languages that do use Latin script don't always use alphabetic sorting. For example, in some cultures, a phone book might not be sorted alphabetically. Windows can handle sorting for you, but if you create your own sorting algorithm then be sure to take into account the sorting methods used in your target markets.
Appropriately format numbers, dates, times, addresses, and phone numbers.	These formats vary between cultures, regions, languages, and markets. If you're displaying these data then use **Globalization** APIs to get the format appropriate for a particular audience. See Globalize your date/time/number formats. The order in which family and given names are displayed, and the format of addresses, can differ as well. Use standard date, time, and number displays. Use standard date and time picker controls. Use standard address information.
Support international units of measurement and currency.	Different units and scales are used in different countries, although the most popular are the metric system and the imperial system. Be sure to support the correct system measurement if you deal with measurements such as length, temperature, and area. Use the **GeographicRegion.CurrenciesInUse** property to get the set of currencies in use in a region.
Use Unicode for character encoding.	By default, Microsoft Visual Studio uses Unicode character encoding for all documents. If you're using a different editor, be sure to save source files in the appropriate Unicode character encodings. All Windows Runtime APIs return UTF-16 encoded strings.

Recommendation	Description
Support international paper sizes.	The most common paper sizes differ between countries/regions, so if you include features that depend on paper size, such as printing, be sure to support and test common international sizes.
Record the language of the keyboard or IME.	When your app asks the user for text input, record the language tag for the currently enabled keyboard layout or Input Method Editor (IME). This ensures that when the input is displayed later it's presented to the user with the appropriate formatting. Use the **Language.CurrentInputMethodLanguageTag** property to get the current input language.
Don't use language to assume a user's region; and don't use region to assume a user's language.	Language and region are separate concepts. A user can speak a particular regional variant of a language, like en-GB for English as spoken in the UK, but the user might be in an entirely different country or region. Consider whether your app requires knowledge about the user's language (for UI text, for example), or region (for licensing, for example). For more info, see Understand user profile languages and app manifest languages.
The rules for comparing language tags are non-trivial.	BCP-47 language tags are complex. There are a number of issues when comparing language tags, including issues with matching script information, legacy tags, and multiple regional variants. The Resource Management System in Windows takes care of matching for you. You can specify a set of resources in any languages, and the system chooses the appropriate one for the user and the app. See App resources and the Resource Management System and How the Resource Management System matches language tags.
Design your UI to accommodate different text lengths and font sizes for labels and text input controls.	Strings translated into different languages can vary greatly in length, so you'll need your UI controls to dynamically size to their content. Common characters in other languages include marks above or below what is typically used in English (such as Å or Ṇ). Use the standard font sizes and line heights to provide adequate vertical space. Be aware that fonts for other languages may require larger minimum font sizes to remain legible. See the classes in the Windows.Globalization.Fonts namespace.
Support the mirroring of reading order.	Text alignment and reading order can be left to right (as in English, for example), or right to left (RTL) (as in Arabic or Hebrew, for example). If you are localizing your product into languages that use a different reading order than your own, then be sure that the layout of your UI elements supports mirroring. Even items such as back buttons, UI transition effects, and images might need to be mirrored. For more info, see Adjust layout and fonts, and support RTL.
Display text and fonts correctly.	The ideal font, font size, and direction of text varies between different markets. For more info, see **Adjust layout and fonts, and support RTL** and International fonts.

Understand user profile languages and app manifest languages

Article • 01/22/2023

A Windows user can use **Settings** > **Time & Language** > **Region & language** to configure an ordered list of preferred display languages, or just a single preferred display language. A language can have a regional variant. For example, you can select Spanish as spoken in Spain, Spanish as spoken in Mexico, Spanish as spoken in the United States, among others.

Also in **Settings** > **Time & Language** > **Region & language**, but separate from language, the user can specify their location (known as region) in the world. Note that the display language (and regional variant) setting isn't a determiner of the region setting, and vice versa. For example, a user might be currently living in France but choose a preferred Windows display language of Español (México).

For Windows apps, a language is represented as a BCP-47 language tag. For example, the BCP-47 language tag "en-US" corresponds to English (United States) in **Settings**. Appropriate Windows Runtime APIs accept and return string representations of BCP-47 language tags.

Also see the IANA language subtag registry.

The following three sections define the terms "user profile language list", "app manifest language list", and "app runtime language list". We'll be using these terms in this topic and other topics in this feature area, so it's important to know what they mean.

User profile language list

The user profile language list is the name of the list that's configured by the user in **Settings** > **Time & Language** > **Region & language** > **Languages**. In code you can use the **GlobalizationPreferences.Languages** property to access the user profile language list as a read-only list of strings, where each string is a single BCP-47 language tag such as "en-US" or "ja-JP".

C#

```
    IReadOnlyList<string> userLanguages =
Windows.System.UserProfile.GlobalizationPreferences.Languages;
```

App manifest language list

The app manifest language list is the list of languages for which your app declares (or will declare) support. This list grows as you progress your app through the development lifecycle all the way to localization.

The list is determined at compile time, but you have two options for controlling exactly how that happens. One option is to let Visual Studio determine the list from the files in your project. To do that, first set your app's **Default language** on the **Application** tab in your app package manifest source file (`Package.appxmanifest`). Then, confirm that the same file contains this configuration (which it does by default).

XML

```
<Resources>
  <Resource Language="x-generate" />
</Resources>
```

Each time Visual Studio produces your built app package manifest file (`AppxManifest.xml`), it expands that single `Resource` element in the source file into a union of all the language qualifiers that it finds in your project (see Tailor your resources for language, scale, high contrast, and other qualifiers). For example, if you've begun localizing and you have string, image, and/or file resources whose folder or file names include "en-US", "ja-JP", and "fr-FR", then your built `AppxManifest.xml` file will contain the following (the first entry in the list is the default language that you set).

XML

```
<Resources>
  <Resource Language="EN-US" />
  <Resource Language="JA-JP" />
  <Resource Language="FR-FR" />
</Resources>
```

The other option is to replace that single "x-generate" `<Resource>` element in your app package manifest source file (`Package.appxmanifest`) with the expanded list of `<Resource>` elements (being careful to list the default language first). That option involves more maintenance work for you, but it might be an appropriate option for you if you use a custom build system.

To begin with, your app manifest language list will only contain one language. Perhaps that's en-US. But eventually—as you either manually configure your manifest, or as you add translated resources to your project—that list will grow.

When your app is in the Microsoft Store, the languages in the app manifest language list are the ones that are displayed to customers. For a list of BCP-47 language tags specifically supported by the Microsoft Store, see Supported languages.

In code you can use the **ApplicationLanguages.ManifestLanguages** property to access the app manifest language list as a read-only list of strings, where each string is a single BCP-47 language tag.

```
C#
```

```
    IReadOnlyList<string> userLanguages =
Windows.Globalization.ApplicationLanguages.ManifestLanguages;
```

App runtime language list

The third language list of interest is the intersection between the two lists that we've just described. At runtime, the list of languages for which your app has declared support (the app manifest language list) is compared with the list of languages for which the user has declared a preference (the user profile language list). The app runtime language list is set to this intersection (if the intersection is not empty), or to just the app's default language (if the intersection is empty).

More specifically, the app runtime language list is made up of these items.

1. **(Optional) Primary Language Override**. The **PrimaryLanguageOverride** is a simple override setting for apps that give users their own independent language choice, or apps that have some strong reason to override the default language choices. To learn more, see the Application resources and localization sample .
2. **The user's languages that are supported by the app**. This is the user profile language list filtered by the app manifest language list. Filtering the user's languages by those supported by the app maintains consistency among software development kits (SDKs), class libraries, dependent framework packages, and the app.
3. **If 1 and 2 are empty, then the default or first language supported by the app**. If the user profile language list doesn't contain any languages that the app supports, then the app runtime language is the first language supported by the app.

In code you can use the ResourceContext.QualifierValues property to access the app runtime language list in the form of a string containing a semicolon-delimited list of BCP-47 language tags.

```
C#
```

```
    string runtimeLanguages =
Windows.ApplicationModel.Resources.Core.ResourceContext.GetForCurrentView().
QualifierValues["Language"];
```

You can also access it as a read-only list of strings, each containing a single BCP-47 language tag. You can use the **ResourceContext.Languages** property or the **ApplicationLanguages.Languages** property to do this.

C#

```
    IReadOnlyList<string> runtimeLanguages =
Windows.ApplicationModel.Resources.Core.ResourceContext.GetForCurrentView().
Languages;

    runtimeLanguages = Windows.Globalization.ApplicationLanguages.Languages;
```

The app runtime language list determines the resources that Windows loads for your app and also the language(s) used to format dates, times, numbers, and other components. See Globalize your date/time/number formats.

Note If the user profile language and the app manifest language are regional variants of one another, then the user's regional variant is used as the app runtime language. For example, if the user prefers en-GB and the app supports en-US, then the app runtime language is en-GB. This ensures that dates, times, and numbers are formatted more closely to the user's expectations (en-GB), but localized resources are still loaded (due to language matching) in the app's supported language (en-US).

Qualify resource files with their language

Name your resource files, or their folders, with language resource qualifiers. To learn more about resource qualifiers, see Tailor your resources for language, scale, high contrast, and other qualifiers. A resource file can be an image (or other asset), or it can be a resource container file, such as a *.resw* that contains text strings.

Note Even resources in your app's default language must specify the language qualifier. For example, if your app's default language is English (United States), then qualify your assets as `\Assets\Images\en-US\logo.png`.

- Windows performs complex matching, including across regional variants such as en-US and en-GB. So include the region sub-tag as appropriate. See How the Resource Management System matches language tags.

- Specify a language script sub-tag in the qualifier when there is no Suppress-Script value defined for the language. For example, instead of zh-CN or zh-TW, use zh-Hant, zh-Hant-TW, or zh-Hans (for more detail, see the IANA language subtag registry).
- For languages that have a single standard dialect, there is no need to include the region qualifier. For example, use ja instead of ja-JP.
- Some tools and other components such as machine translators might find specific language tags, such as regional dialect info, helpful in understanding the data.

Not all resources need to be localized

Localization might not be required for all resources.

- At a minimum, ensure all resources exist in the default language.
- A subset of some resources might suffice for a closely related language (partial localization). For example, you might not localize all of your app's UI into Catalan if your app has a full set of resources in Spanish. For users who speak Catalan and then Spanish, the resources that are not available in Catalan appear in Spanish.
- Some resources might require exceptions for specific languages, while the majority of other resources map to a common resource. In this case, mark the resource intended to be used for all languages with the undetermined language tag 'und'. Windows interprets the 'und' language tag as a wildcard (similar to '*') in that it matches the top app language after any other specific match. For example, if a few resources are different for Finnish, but the rest of the resources are the same for all languages, then the Finnish resource should be marked with the Finnish language tag, and the rest should be marked with 'und'.
- For resources that are based on a language script, such as a font or height of text, use the undetermined language tag with a specified script: 'und-<script>'. For example, for Latin fonts use `und-Latn\\fonts.css` and for Cyrillic fonts use `und-Cryl\\fonts.css`.

Set the HTTP Accept-Language request header

Consider whether the web services that you call have the same extent of localization as your app does. HTTP requests made from Windows apps in typical web requests, and XMLHttpRequest (XHR), use the standard HTTP Accept-Language request header. By default, the HTTP header is set to the user profile language list. Each language in the list is further expanded to include neutrals of the language and a weighting (q). For example, a user's language list of fr-FR and en-US results in an HTTP Accept-Language request header of fr-FR, fr, en-US, en ("fr-FR,fr;q=0.8,en-US;q=0.5,en;q=0.3"). But if your

weather app (for example) is displaying a UI in French (France), but the user's top language in their preference list is German, then you'll need to explicitly request French (France) from the service in order to remain consistent within your app.

APIs in the Windows.Globalization namespace

Typically, the APIs in the **Windows.Globalization** namespace use the app runtime language list to determine the language. If none of the languages has a matching format, then the user locale is used. This is the same locale that is used for the system clock. The user locale is available from **Settings** > **Time & Language** > **Region & language** > **Additional date, time, & regional settings** > **Region: Change date, time, or number formats**. The **Windows.Globalization** APIs also have overrides to specify a list of languages to use, instead of the app runtime language list.

Using the **Language** class, you can inspect details about a particular language, such as the script of the language, the display name, and the native name.

Use geographic region when appropriate

In **Settings** > **Time & Language** > **Region & language** > **Country or region**, the user can specify their location in the world. You can use this settings, instead of language, for choosing what content to display to the user. For example, a news app might default to displaying content from this region.

In code, you can access this setting by using the **GlobalizationPreferences.HomeGeographicRegion** property.

Using the **GeographicRegion** class, you can inspect details about a particular region, such as its display name, native name, and currencies in use.

Examples

The following table contains examples of what the user would see in your app's UI under various language and region settings.

Expand table

App manifest language list	User profile language list	App's primary language override (optional)	App runtime language list	What the user sees in the app
English (GB) (default); German (Germany)	English (GB)	none	English (GB)	UI: English (GB) Dates/Times/Numbers: English (GB)
German (Germany) (default); French (France); Italian (Italy)	French (Austria)	none	French (Austria)	UI: French (France) (fallback from French (Austria)) Dates/Times/Numbers: French (Austria)
English (US) (default); French (France); English (GB)	English (Canada); French (Canada)	none	English (Canada); French (Canada)	UI: English (US) (fallback from English (Canada)) Dates/Times/Numbers: English (Canada)
Spanish (Spain) (default); Spanish (Mexico); Spanish (Latin America); Portuguese (Brazil)	English (US)	none	Spanish (Spain)	UI: Spanish (Spain) (uses default since no fallback available for English) Dates/Times/Numbers Spanish (Spain)
Catalan (default); Spanish (Spain); French (France)	Catalan; French (France)	none	Catalan; French (France)	UI: Mostly Catalan and some French (France) because not all the strings are in Catalan Dates/Times/Numbers: Catalan
English (GB) (default); French (France); German (Germany)	German (Germany); English (GB)	English (GB) (chosen by user in app's UI)	English (GB); German (Germany)	UI: English (GB) (language override) Dates/Times/Numbers English (GB)

Globalize your date/time/number formats

Article • 06/24/2021

Design your app to be global-ready by appropriately formatting dates, times, numbers, phone numbers, and currencies. You'll then be able later to adapt your app for additional cultures, regions, and languages in the global market.

Introduction

When creating your app, if you think more broadly than a single language and culture then you'll have fewer (if any) unexpected issues when your app grows into new markets. For example, dates, times, numbers, calendars, currency, telephone numbers, units of measurement, and paper sizes are all items that can be displayed differently in different cultures or languages.

Different regions and cultures use different date and time formats. These include conventions for the order of day and month in the date, for the separation of hours and minutes in the time, and even for what punctuation is used as a separator. In addition, dates may be displayed in various long formats ("Wednesday, March 28, 2012") or short formats ("3/28/12"), which vary across cultures. And, of course, the names and abbreviations for the days of the week and months of the year differ between languages.

You can preview the formats used for different languages. Go to **Settings** > **Time & Language** > **Region & language**, and click **Additional date, time, & regional settings** > **Change date, time, or number formats**. On the **Formats** tab, select a language from the **Format** drop-down and preview the formats in **Examples**.

This topic uses the terms "user profile language list", "app manifest language list", and "app runtime language list". For details on exactly what those terms mean and how to access their values, see Understand user profile languages and app manifest languages.

Format dates and times for the app runtime language list

If you need to allow users to choose a date, or to select a time, then use the standard calendar, date, and time controls. These automatically use the best date and time format for the app runtime language list.

If you need to display dates or times yourself then you can use the **DateTimeFormatter** class. By default, **DateTimeFormatter** automatically uses the best date and time format for the app runtime language list. So, the code below formats a given **DateTime** in the best way for that list. As an example, assume that your app manifest language list includes English (United States), which is also your default, and German (Germany). If the current date is Nov 6 2017 and the user profile language list contains German (Germany) first, then the formatter gives "06.11.2017". If the user profile language list contains English (United States) first (or if it contains neither English nor German), then the formatter gives "11/6/2017" (since "en-US" matches, or is used as the default).

C#

```
    // Use the DateTimeFormatter class to display dates and times using
basic formatters.

    var shortDateFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("shortdate");
    var shortTimeFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("shorttime");

    var dateTimeToFormat = DateTime.Now;

    var shortDate = shortDateFormatter.Format(dateTimeToFormat);
    var shortTime = shortTimeFormatter.Format(dateTimeToFormat);

    var results = "Short Date: " + shortDate + "\n" +
                  "Short Time: " + shortTime;
```

You can test the code above on your own PC like this.

- Make sure that you have resource files in your project qualified for both "en-US" and "de-DE" (see Tailor your resources for language, scale, high contrast, and other qualifiers).
- Change your user profile language list in **Settings** > **Time & Language** > **Region & language** > **Languages**. Add German (Germany), make it the default, and run the code again.

Format dates and times for the user profile language list

Remember that, by default, **DateTimeFormatter** matches the app runtime language list. That way, if you display strings such as "The date is <date>", then the language will match the date format.

If for whatever reason you want to format dates and/or times only according to the user profile language list, then you can do that using code like the example below. But if you do so then understand that the user can choose a language for which your app doesn't have translated strings. For example, if your app is not localized into German (Germany), but the user chooses that as their preferred language, then that could result in the display of arguably odd-looking strings such as "The date is 06.11.2017".

C#

```
    // Use the DateTimeFormatter class to display dates and times using
basic formatters.

    var userLanguages =
Windows.System.UserProfile.GlobalizationPreferences.Languages;

    var shortDateFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("shortdate",
userLanguages);

    var results = "Short Date: " + shortDateFormatter.Format(DateTime.Now);
```

Format numbers and currencies appropriately

Different cultures format numbers differently. Format differences may include how many decimal digits to display, what characters to use as decimal separators, and what currency symbol to use. Use classes in the **NumberFormatting** namespace to display decimal, percent, or permille numbers, and currencies. Most of the time, you will want these formatter classes to use the best format for the user profile. But you may use the formatters to display a currency for any region or format.

This example shows how to display currencies both per the user profile, and for a specific given currency system.

C#

```
    // This scenario uses the CurrencyFormatter class to format a number as
a currency.

    var userCurrency =
Windows.System.UserProfile.GlobalizationPreferences.Currencies[0];

    var valueToBeFormatted = 12345.67;

    var userCurrencyFormatter = new
Windows.Globalization.NumberFormatting.CurrencyFormatter(userCurrency);
    var userCurrencyValue =
userCurrencyFormatter.Format(valueToBeFormatted);
```

```
    // Create a formatter initialized to a specific currency,
    // in this case US Dollar (specified as an ISO 4217 code)
    // but with the default number formatting for the current user.
    var currencyFormatUSD = new
Windows.Globalization.NumberFormatting.CurrencyFormatter("USD");
    var currencyValueUSD = currencyFormatUSD.Format(valueToBeFormatted);

    // Create a formatter initialized to a specific currency.
    // In this case it's the Euro with the default number formatting for
France.
    var currencyFormatEuroFR = new
Windows.Globalization.NumberFormatting.CurrencyFormatter("EUR", new[] { "fr-
FR" }, "FR");
    var currencyValueEuroFR =
currencyFormatEuroFR.Format(valueToBeFormatted);

    // Results for display.
    var results = "Fixed number (" + valueToBeFormatted + ")\n" +
                  "With user's default currency: " + userCurrencyValue +
"\n" +
                  "Formatted US Dollar: " + currencyValueUSD + "\n" +
                  "Formatted Euro (fr-FR defaults): " +
currencyValueEuroFR;
```

You can test the code above on your own PC by changing the country or region in **Settings** > **Time & Language** > **Region & language** > **Country or region**. Choose a country or region (perhaps Iceland), and run the code again.

Use a culturally appropriate calendar

The calendar differs across regions and languages. The Gregorian calendar is not the default for every region. Users in some regions may choose alternate calendars, such as the Japanese era calendar, or Arabic lunar calendars. Dates and times on the calendar are also sensitive to different time zones and daylight-saving time.

To ensure that the preferred calendar format is used, you can use the standard calendar, date, and time controls. For more complex scenarios, where working directly with operations on calendar dates may be required, **Windows.Globalization** provides a **Calendar** class that gives an appropriate calendar representation for the given culture, region, and calendar type.

Format phone numbers appropriately

Phone numbers are formatted differently across regions. The number of digits, how the digits are grouped, and the significance of certain parts of the phone number vary

between countries/regions. Starting in Windows 10, version 1607, you can use classes in the **PhoneNumberFormatting** namespace to format phone numbers appropriately for the current region.

PhoneNumberInfo parses a string of digits and allows you to: determine whether the digits are a valid phone number in the current region; compare two numbers for equality; and to extract the different functional parts of the phone number, such as country code or geographical area code.

PhoneNumberFormatter formats a string of digits or a **PhoneNumberInfo** for display, even when the string of digits represents a partial phone number. You can use this partial number formatting to format a number as a user is entering the number.

The example below shows how to use **PhoneNumberFormatter** to format a phone number as it is being entered. Each time text changes in a **TextBox** named phoneNumberInputTextBox, the contents of the text box are formatted using the current default region and displayed in a **TextBlock** named phoneNumberOutputTextBlock. For demonstration purposes, the string is also formatted using the region for New Zealand, and displayed in a TextBlock named phoneNumberOutputTextBlockNZ.

C#

```
    using Windows.Globalization.PhoneNumberFormatting;

    PhoneNumberFormatter currentFormatter, NZFormatter;

    public MainPage()
    {
        this.InitializeComponent();

        // Use the default formatter for the current region
        this.currentFormatter = new PhoneNumberFormatter();

        // Create an explicit formatter for New Zealand.
        PhoneNumberFormatter.TryCreate("NZ", out this.NZFormatter);
    }

    private void phoneNumberInputTextBox_TextChanged(object sender,
TextChangedEventArgs e)
    {
        // Format for the default region.
        this.phoneNumberOutputTextBlock.Text =
currentFormatter.FormatPartialString(this.phoneNumberInputTextBox.Text);

        // If the NZFormatter was created successfully, format the partial
string for the NZ TextBlock.
        if(this.NZFormatter != null)
        {
            this.phoneNumberOutputTextBlockNZ.Text =
```

```
this.NZFormatter.FormatPartialString(this.phoneNumberInputTextBox.Text);
        }
    }
```

You can test the code above on your own PC by changing the country or region in **Settings** > **Time & Language** > **Region & language** > **Country or region**. Choose a country or region (perhaps New Zealand to confirm that the formats match), and run the code again. For test data, you can do a web search for the phone number of a business in New Zealand.

The user's language and cultural preferences

For scenarios where you wish to provide different functionality based solely on the user's language, region, or cultural preferences, Windows gives you a way to access those preferences, through **Windows.System.UserProfile.GlobalizationPreferences**. When needed, use the **GlobalizationPreferences** class to get the value of the user's current geographic region, preferred languages, preferred currencies, and so on. But remember that if your app's strings/images aren't localized for the user's preferred language then dates and times and other data formatted for that preferred language won't match the strings that you display.

Use templates and patterns to format dates and times

Article • 06/24/2021

Use classes in the Windows.Globalization.DateTimeFormatting namespace with custom templates and patterns to display dates and times in exactly the format you wish.

Introduction

The DateTimeFormatter class provides various ways to properly format dates and times for languages and regions around the world. You can use standard formats for year, month, day, and so on. Or you can pass a format template to the *formatTemplate* argument of the **DateTimeFormatter** constructor, such as "longdate" or "month day".

But when you want even more control over the order and format of the components of the DateTime object you wish to display, you can pass a format pattern to the *formatTemplate* argument of the constructor. A format pattern uses a special syntax, which allows you to obtain individual components of a **DateTime** object—just the month name, or just the year value, for example—in order to display them in whatever custom format you choose. Furthermore, the pattern can be localized to adapt to other languages and regions.

Note This is only an overview of format patterns. For a more complete discussion of format templates and format patterns see the Remarks section of the DateTimeFormatter class.

The difference between format templates and format patterns

A format template is a culture-agnostic format string. So, if you construct a **DateTimeFormatter** using a format template, then the formatter displays your format components in the right order for the current language. Conversely, a format pattern is culture-specific. If you construct a **DateTimeFormatter** using a format pattern, then the formatter will use the pattern exactly as given. Consequently, a pattern isn't necessarily valid across cultures.

Let's illustrate this distinction with an example. We'll pass a simple format template (not a pattern) to the **DateTimeFormatter** constructor. This is the format template "month day".

C#

```
var dateFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("month day");
```

This creates a formatter based on the language and region value of the current context. The order of the components in a format template doesn't matter; the formatter displays them in the right order for the current language. So, it displays "January 1" for English (United States), "1 janvier" for French (France), and "1月1日" for Japanese.

On the other hand, a format pattern is culture-specific. Let's access the format pattern for our format template.

C#

```
IReadOnlyList<string> monthDayPatterns = dateFormatter.Patterns;
```

This yields different results depending on the runtime language and region. Different regions might use different components, in different orders, with or without additional characters and spacing.

syntax

```
En-US: "{month.full} {day.integer}"
Fr-FR: "{day.integer} {month.full}"
Ja-JP: "{month.integer}月{day.integer}日"
```

In the example above, we inputted a culture-agnostic format string, and we got back a culture-specific format string (which was a function of the language and region that happened to be in effect when we called `dateFormatter.Patterns`). It follows therefore that if you construct a **DateTimeFormatter** from a culture-specific format pattern, then it will only be valid for specific languages/regions.

C#

```
var dateFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("{month.full}
{day.integer}");
```

The formatter above returns culture-specific values for the individual components inside the brackets {}. But the order of components in a format pattern is invariant. You get precisely what you ask for, which may or may not be culturally appropriate. This

formatter is valid for English (United States), but not for French (France) nor for Japanese.

syntax

```
En-US: January 1
Fr-FR: janvier 1 (inappropriate for France; non-standard order)
Ja-JP: 1月1 (inappropriate for Japan; the day symbol 日 is missing)
```

Furthermore, a pattern that's correct today might not be correct in the future. Countries or regions might change their calendar systems, which alters a format template. Windows updates the output of formatters based on format templates to accommodate such changes. Therefore, you should only use the pattern syntax under one or more of these conditions.

- You are not dependent on a particular output for a format.
- You do not need the format to follow some culture-specific standard.
- You specifically intend the pattern to be invariant across cultures.
- You intend to localize the actual format pattern string itself.

Here's a summary of the distinction between format templates and format patterns.

Format templates, such as "month day"

- Abstracted representation of a DateTime format that includes values for the month, day, etc., in any order.
- Guaranteed to return a valid standard format across all language-region values supported by Windows.
- Guaranteed to give you a culturally-appropriate formatted string for the given language-region.
- Not all combinations of components are valid. For example, "dayofweek day" is not valid.

Format patterns, such as "{month.full} {day.integer}"

- Explicitly ordered string that expresses the full month name, followed by a space, followed by the day integer, in that order, or whatever specific format pattern you specify.
- May not correspond to a valid standard format for any language-region pair.
- Not guaranteed to be culturally appropriate.
- Any combination of components may be specified, in any order.

Examples

Suppose you wish to display the current month and day together with the current time, in a specific format. For example, you would like US English users to see something like this:

syntax

```
June 25 | 1:38 PM
```

The date part corresponds to the "month day" format template, and the time part corresponds to the "hour minute" format template. So, you can construct formatters for the relevant date and time format templates, and then concatenate their output together using a localizable format string.

C#

```
var dateToFormat = System.DateTime.Now;
var resourceLoader =
Windows.ApplicationModel.Resources.ResourceLoader.GetForCurrentView();

var dateFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("month day");
var timeFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("hour minute");

var date = dateFormatter.Format(dateToFormat);
var time = timeFormatter.Format(dateToFormat);

string output =
string.Format(resourceLoader.GetString("CustomDateTimeFormatString"), date,
time);
```

`CustomDateTimeFormatString` is a resource identifier referring to a localizable resource in a Resources File (.resw). For a default language of English (United States), this would be set to a value of "{0} | {1}" along with a comment indicating that "{0}" is the date and "{1}" is the time. That way, translators can adjust the format items as needed. For example, they can change the order of the items if it seems more natural in some language or region to have the time precede the date. Or, they can replace "|" with some other separator character.

Another way to implement this example is to query the two formatters for their format patterns, concatenate those together, and then construct a third formatter from the resultant format pattern.

C#

```
var resourceLoader =
Windows.ApplicationModel.Resources.ResourceLoader.GetForCurrentView();

var dateFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("month day");
var timeFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter("hour minute");

string dateFormatterPattern = dateFormatter.Patterns[0];
string timeFormatterPattern = timeFormatter.Patterns[0];

string pattern =
string.Format(resourceLoader.GetString("CustomDateTimeFormatString"),
dateFormatterPattern, timeFormatterPattern);

var patternFormatter = new
Windows.Globalization.DateTimeFormatting.DateTimeFormatter(pattern);

string output = patternFormatter.Format(System.DateTime.Now);
```

Adjust layout and fonts, and support RTL

Article • 06/24/2021

Design your app to support the layouts and fonts of multiple languages, including RTL (right-to-left) flow direction. Flow direction is the direction in which script is written and displayed, and the UI elements on the page are scanned by the eye.

Layout guidelines

Languages such as German and Finnish typically use more characters than English does. East Asian fonts typically require more height. And languages such as Arabic and Hebrew require that layout panels and text elements be laid out in right-to-left (RTL) reading order.

Because of these variations in the metrics of translated text, we recommend that you don't bake absolute positioning, fixed widths, or fixed heights into your user interface (UI). Instead, take advantage of the dynamic layout mechanisms that are built into the Windows UI elements. For example, content controls (such as buttons), items controls (such as grid views and list views), and layout panels (such as grids and stackpanels) automatically resize and reflow by default to fit their content. Pseudo-localize your app to uncover any problematic edge cases where your UI elements don't size to content properly.

Dynamic layout is the recommended technique, and you'll be able to use it in the majority of cases. Less preferable, but still better than baking sizes into your UI markup, is to set layout values as a function of language. Here's an example of how you can expose a Width property in your app as a resource that localizers can set appropriately per language. First, in your app's Resources File (.resw), add a property identifier with the name "TitleText.Width" (instead of "TitleText", you can use any name you like). Then, use an **x:Uid** to associate one or more UI elements with this property identifier.

XAML

```
<TextBlock x:Uid="TitleText">
```

For more info about Resources Files (.resw), property identifiers, and **x:Uid**, see Localize strings in your UI and app package manifest.

Fonts

Use the **LanguageFont** font-mapping class for programmatic access to the recommended font family, size, weight, and style for a particular language. The **LanguageFont** class provides access to the correct font info for various categories of content including UI headers, notifications, body text, and user-editable document body fonts.

Mirroring images

If your app has images that must be mirrored (that is, the same image can be flipped) for RTL, then you can use **FlowDirection**.

XAML

```
<!-- en-US\localized.xaml -->
<Image ... FlowDirection="LeftToRight" />

<!-- ar-SA\localized.xaml -->
<Image ... FlowDirection="RightToLeft" />
```

If your app requires a different image to flip the image correctly, then you can use the resource management system with the `LayoutDirection` qualifier (see the LayoutDirection section of Tailor your resources for language, scale, and other qualifiers). The system chooses an image named `file.layoutdir-rtl.png` when the app runtime language (see Understand user profile languages and app manifest languages) is set to an RTL language. This approach may be necessary when some part of the image is flipped, but another part isn't.

Handling right-to-left (RTL) languages

When your app is localized for right-to-left (RTL) languages, use the **FrameworkElement.FlowDirection** property, and set symmetrical padding and margins. Layout panels such as **Grid** scale and flip automatically with the value of **FlowDirection** that you set.

Set **FlowDirection** on the root layout panel (or frame) of your Page, or on the Page itself. This causes all of the controls contained within to inherit that property.

> ⓘ **Important**

However, **FlowDirection** is *not* set automatically based on the user's selected display language in Windows settings; nor does it change dynamically in response to the user switching display language. If the user switches Windows settings from English to Arabic, for example, then the **FlowDirection** property will *not* automatically change from left-to-right to right-to-left. As the app developer, you have to set **FlowDirection** appropriately for the language that you are currently displaying.

The programmatic technique is to use the `LayoutDirection` property of the preferred user display language to set the **FlowDirection** property (see the code example below). Most controls included in Windows use **FlowDirection** already. If you're implementing a custom control, it should use **FlowDirection** to make appropriate layout changes for RTL and LTR languages.

C#

```
this.languageTag = Windows.Globalization.ApplicationLanguages.Languages[0];

// For bidirectional languages, determine flow direction for the root layout
panel, and all contained UI.

var flowDirectionSetting =
Windows.ApplicationModel.Resources.Core.ResourceContext.GetForCurrentView().
QualifierValues["LayoutDirection"];
if (flowDirectionSetting == "LTR")
{
    this.layoutRoot.FlowDirection =
Windows.UI.Xaml.FlowDirection.LeftToRight;
}
else
{
    this.layoutRoot.FlowDirection =
Windows.UI.Xaml.FlowDirection.RightToLeft;
}
```

C++/WinRT

```
#include <winrt/Windows.ApplicationModel.Resources.Core.h>
#include <winrt/Windows.Globalization.h>
...

m_languageTag =
Windows::Globalization::ApplicationLanguages::Languages().GetAt(0);

// For bidirectional languages, determine flow direction for the root layout
panel, and all contained UI.

auto flowDirectionSetting =
```

```
Windows::ApplicationModel::Resources::Core::ResourceContext::GetForCurrentVi
ew().QualifierValues().Lookup(L"LayoutDirection");
if (flowDirectionSetting == L"LTR")
{

layoutRoot().FlowDirection(Windows::UI::Xaml::FlowDirection::LeftToRight);
}
else
{

layoutRoot().FlowDirection(Windows::UI::Xaml::FlowDirection::RightToLeft);
}
```

C++

```
this->languageTag = Windows::Globalization::ApplicationLanguages::Languages-
>GetAt(0);

// For bidirectional languages, determine flow direction for the root layout
panel, and all contained UI.

auto flowDirectionSetting =
Windows::ApplicationModel::Resources::Core::ResourceContext::GetForCurrentVi
ew()->QualifierValues->Lookup("LayoutDirection");
if (flowDirectionSetting == "LTR")
{
    this->layoutRoot->FlowDirection =
Windows::UI::Xaml::FlowDirection::LeftToRight;
}
else
{
    this->layoutRoot->FlowDirection =
Windows::UI::Xaml::FlowDirection::RightToLeft;
}
```

The technique above makes **FlowDirection** a function of the `LayoutDirection` property of the preferred user display language. If for whatever reason you don't want that logic, then you can expose a FlowDirection property in your app as a resource that localizers can set appropriately for each language they translate into.

First, in your app's Resources File (.resw), add a property identifier with the name "MainPage.FlowDirection" (instead of "MainPage", you can use any name you like). Then, use an **x:Uid** to associate your main **Page** element (or its root layout panel or frame) with this property identifier.

XAML

```
<Page x:Uid="MainPage">
```

Instead of a single line of code for all languages, this depends on the translator "translating" this property resource correctly for each translated language; so be aware that there's that extra opportunity for human error when you use this technique.

NumeralSystem values

Article • 06/24/2021

This topic lists the values available to the **NumeralSystem** property of various classes in the Windows.Globalization namespace. These classes contain a **NumeralSystem** property.

- Windows.Globalization.Calendar
- Windows.Globalization.NumberFormatting.CurrencyFormatter
- Windows.Globalization.NumberFormatting.DecimalFormatter
- Windows.Globalization.NumberFormatting.NumeralSystemTranslator
- Windows.Globalization.NumberFormatting.PercentFormatter
- Windows.Globalization.NumberFormatting.PermilleFormatter
- Windows.Globalization.NumberFormatting.INumberFormatterOptions

The **NumeralSystem** property indicates the numeral system used by the class. The property is a string such as "Latn" for the Latin numeral system (0123456789), or "Arab" for the Arabic-Indic numeral system (٠١٢٣٤٥٦٧٨٩).

These are the values for **NumeralSystem** that are supported in Windows.

NumeralSystem value	Description	Unicode code points
Arab	Arabic-Indic	U+0660, U+0661, U+0662, U+0663, U+0664, U+0665, U+0666, U+0667, U+0668, U+0669
ArabExt	Extended Arabic-Indic	U+06F0, U+06F1, U+06F2, U+06F3, U+06F4, U+06F5, U+06F6, U+06F7, U+06F8, U+06F9

Make your app localizable

Article • 06/24/2021

A localized app is one that can be localized for other markets, languages, or regions without uncovering any functional defects in the app. The most essential property of a localizable app is that its executable code has been cleanly separated from its localizable resources. So, you should determine which of your app's resources need to be localized. Ask yourself what needs to change if your app is to be localized for other markets.

We also recommend that you become familiar with the guidelines for globalization.

Put your strings into Resources Files (.resw)

Don't hard-code string literals in your imperative code, XAML markup, nor in your app package manifest. Instead, put your strings into Resources Files (.resw) so that they can be adapted to different local markets independently of your app's built binaries. For details, see Localize strings in your UI and app package manifest.

That topic also shows you how to add comments to your default Resources File (.resw). For example, if you are adopting an informal voice or tone then be sure to explain that in comments. Also, to minimize expense, confirm that only the strings that need to be translated are provided to translators.

Set the default language for your app appropriately in your app package manifest source file (the `Package.appxmanifest` file). The default language determines the language that's used when the user's preferred languages don't match any of the supported languages of your app. Mark all of your resources with their language (even the ones in your default language, for example `\Assets\en-us\Logo.png`) so that the system can tell which language the resource is in and how it's used in particular situations.

Tailor your images and other file resources for language

Ideally, you will be able to globalize your images—that is, make them culture-independent. For any images and other file resources where that's not possible, create as many different variants of them as you need and put the appropriate language qualifiers into their file or folder names. To learn more, see Tailor your resources for language, scale, high contrast, and other qualifiers.

To minimize localization costs, don't put text nor culturally-sensitive material into images to begin with. An image that's appropriate in your own culture might be offensive or misinterpreted in other cultures. Avoid the use of culture-specific images such as mailboxes, which are not common around the world. Avoid religious symbols, animals, political, or gender-specific images. The display of flesh, body parts, or hand gestures can also be a sensitive topic. If you can't avoid all of these, then your images will need to be thoughtfully localized. If you're localizing to a language with a different reading direction than your own, using symmetrical images and effects make it easier to support mirroring.

Also avoid the use of text in images, and speech in audio/video files.

The use of color in your app

Be mindful when using color. Using color combinations that are associated with national flags or political movements can be problematic. Color choices may need to be reviewed by culture experts. There is also an accessibility issues with using color. If you use color to convey meaning then you should also convey that same information by some other means, such as size, shape, or a label.

Consider factoring your strings into sentences

Use appropriately-sized strings. Short strings are easier to translate, and they enable translation recycling (which saves expense because the same string isn't sent to the localizer more than once). Also, extremely long strings might not be supported by localization tools.

But in tension with this guideline is the risk of re-using a string in different contexts. Even simple words such as "on" and "off" might be translated differently, depending on the context. In the English language, "on" and "off" can be used for a toggle for Flight Mode, Bluetooth, and devices. But in Italian, the translation depends on the context of what is being turned on and off. You would need to create a pair of strings for each context. You can reuse strings if the two contexts are the same. For instance, you can reuse the string "Volume" for both sound effect volume and music volume because both refer to intensity of sound. You should not reuse that same string when referring to a hard disk volume because the context and meaning are different, and the word might be translated differently.

Additionally, a string like "text" or "fax" could be used as both a verb and a noun in the English language, which can confuse the translation process. Instead, create a separate

string for both the verb and noun format. When you're not sure whether the contexts are the same, err on the safe side and use a distinct string.

In short, factor your strings into pieces that work in all contexts. There will be cases where a string will need to be an entire sentence.

Consider the following string: "The {0} could not be synchronized."

A variety of words could replace {0}, such as "appointment", "task", or "document". While this example works for the English language, it will not work in all cases for the corresponding sentence in, for example, German. Notice that in the following German sentences, some of the words in the template string ("Der", "Die", "Das") need to match the parameterized word:

English	German
The appointment could not be synchronized.	Der Termin konnte nicht synchronisiert werden.
The task could not be synchronized.	Die Aufgabe konnte nicht synchronisiert werden.
The document could not be synchronized.	Das Dokument konnte nicht synchronisiert werden.

As another example, consider the sentence "Remind me in {0} minute(s)." Using "minute(s)" works for the English language, but other languages might use different terms. For example, the Polish language uses "minuta", "minuty", or "minut" depending on the context.

To solve this problem, localize the entire sentence, rather than a single word. Doing this may seem like extra work and an inelegant solution, but it is the best solution because:

- A grammatically correct message will be displayed for all languages.
- Your translator will not need to ask about what the strings will be replaced with.
- You will not need to implement a costly code fix when a problem like this surfaces after your app is completed.

Other considerations for strings

Avoid colloquialisms and metaphors in the strings that you author in your default language. Language that's specific to a demographic group, such as culture and age, can be hard to understand or translate because only people in that demographic group use that language. Similarly, metaphors might make sense to one person but mean nothing to someone else. For example, a "bluebird" means something specific to those

who are part of skiing culture, but those who aren't part of that culture don't understand the reference.

Don't use technical jargon, abbreviations, or acronyms. Technical language is less likely to be understood by non-technical audiences or people from other cultures or regions, and it's difficult to translate. People don't use these kinds of words in everyday conversations. Technical language often appears in error messages to identify hardware and software issues, but you should strings to be technical *only if the user needs that level of information, and can either action it or find someone who can*.

Using an informal voice or tone in your strings is a valid choice. You can use comments in your default Resources File (.resw) to indicate that intention.

Pseudo-localization

Pseudo-localize your app to uncover any localizability issues. Pseudo-localization is a kind of localization dry-run, or disclosure test. You produce a set of resources that are not really translated; they only look that way. Your strings are approximately 40% longer than in the default language, for example, and they have delimiters in them so that you can see at a glance whether they have been truncated in the UI.

Deployment Considerations

When you install an app that contains localized language data, you might find that only the default language is available for the app even though you initially included resources for multiple languages. This is because the installation process is optimized to only install language resources that match the current language and culture of the device. Therefore, if your device is configured for en-US, only the en-US language resources are installed with your app.

> **Note**
>
> It is not possible to install additional language support for your app after the initial installation. If you change the default language after installing an app, the app continues to use only the original language resources.

If you want to ensure all language resources are available after installation, create a configuration file for the app package that specifies that certain resources are required during installation (including language resources). This optimized installation feature is automatically enabled when your application's .appxbundle is generated during

packaging. For more information, see Ensure that resources are installed on a device regardless of whether a device requires them.

Optionally, to ensure all resources are installed (not just a subset), you can disable .appxbundle generation when you package your app. This is not recommended however as it can increase the installation time of your app.

Disable automatic generation of the .appxbundle by setting the "Generate App Bundle" attribute to “never”:

1. In Visual Studio, right-click the project name
2. Select **Store** -> **Create app packages...**
3. In the **Create Your Packages** dialog, select **I want to create packages to upload to the Microsoft Store using a new app name** and then click **Next**.
4. In the **Select an app name** dialog, select/create an app name for your package.
5. In the **Select and Configure Packages** dialog, set **Generate app bundle** to **Never**.

Geopolitical awareness

Avoid political offense in maps or when referring to regions. Maps might include controversial regional or national boundaries, and they're a frequent source of political offense. Be careful that any UI used for selecting a nation refers to it as a "country/region". Listing a disputed territory in a list labeled "countries"—such as in an address form—might offend some users.

Language- and region-changed events

Subscribe to events that are raised when the system's language and region settings change. Do this so that you can re-load resources, if appropriate. For details, see Updating strings in response to qualifier value change events and Updating images in response to qualifier value change events.

Ensure the correct parameter order when formatting strings

Don't assume that all languages express parameters in the same order. For example, consider this format.

```
C#
```

```
    string.Format("Every {0} {1}", monthName, dayNumber); // For example,
"Every April 1".
```

The format string in this example works for English (United States). But it is not appropriate for German (Germany), for example, where the day and month are displayed in the reverse order. Ensure that the translator knows the intent of each of the parameters so that they can reverse the order of the format items in the format string (for example, "{1} {0}") as appropriate for the target language.

Don’t over-localize

Only submit natural language to translators; not programming language nor markup. A `<link>` tag is not natural language. Consider these examples.

Don't localize this	Localize this
<link>terms of use</link>	terms of use
<link>privacy policy</link>	privacy policy

Including the `<link>` tag in your Resources File (.resw) means that it, too, is likely to be translated. That would render the tag invalid. If you have long strings that need to include markup in order to maintain context and ensure ordering, then make it clear in comments what not to translate.

Choose an appropriate translation approach

After strings are separated into resource files, they can be translated. The ideal time to translate strings is after the strings in your project are finalized, which usually happens toward the end of a project. You can approach the translation process in number of ways. This may depend on the volume of strings to be translated, the number of languages to be translated, and how the translation will be done (such as in-house versus hiring an external vendor).

Consider these options.

- **The resource files can be translated by opening them directly in the project.** This approach works well for a project that has a small volume of strings that need to be translated into two or three languages. It could be suitable for a scenario where a developer speaks more than one language and is willing to handle the translation process. This approach benefits from being quick, requires no tools,

and minimizes the risk of mistranslations. But it is not scalable. In particular, the resources in different languages can easily get out of sync, causing bad user experiences and maintenance headaches.

- **The string resource files are in XML or ResJSON text format, so could be handed off for translation using any text editor. The translated files would then be copied back into the project.** This approach carries a risk of translators accidentally editing the XML tags, but it lets translation work take place outside of the Microsoft Visual Studio project. This approach could work well for projects that need to be translated into a small number of languages. The XLIFF format is an XML format specifically designed for use in localization, and should be well supported by some localization vendors or localization tools. You can use the Multilingual App Toolkit to generate XLIFF files from other resource files, such as .resw or .resjson.

> **Note**
>
> Localization might also be necessary for other assets, including images and audio files.

You should also consider the following:

- **Localization tools** A number of localization tools are available for parsing resource files and allowing only the translatable strings to be edited by translators. This approach reduces the risk of a translator accidentally editing the XML tags. But it has the drawback of introducing a new tool and process to the localization process. A localization tool is good for projects with a large volume of strings but a small number of languages. To learn more, see How to use the Multilingual App Toolkit.
- **Localization vendors** Consider using a localization vendor if your application contains extensive strings that need to be translated into a large number of languages. A localization vendor can give advice about tools and processes, as well as translating your resource files. This is an ideal solution, but is also the most costly option, and may increase the turnaround time for your translated content.

Keep access keys and labels consistent

It is a challenge to "synchronize" the access keys used in accessibility with the display of the localized access keys, because the two string resources are categorized in two separate sections. Be sure to provide comments for the label string such as: `Make sure that the emphasized shortcut key is synchronized with the access key.`

Support furigana for Japanese strings that can be sorted

Japanese kanji characters have the property of having more than one reading (pronunciation) depending on the word in which they are used. This leads to problems when you try to sort Japanese named objects, such as application names, files, songs, and so on. Japanese kanji have, in the past, usually been sorted in a machine-understandable order called XJIS. Unfortunately, because this sorting order is not phonetic it is not very useful for humans.

Furigana works around this problem by allowing the user or creator to specify the phonetics for the characters they are using. If you use the following procedure to add furigana to your app name, you can ensure that it is sorted in the proper location in the app list. If your app name contains kanji characters and furigana is not provided when the user's UI language or the sort order is set to Japanese, Windows makes its best effort to generate the appropriate pronunciation. However, there is a possibility for app names containing rare or unique readings to be sorted under a more common reading instead. Therefore, the best practice for Japanese applications (especially those containing kanji characters in their names) is to provide a furigana version of their app name as part of the Japanese localization process.

1. Add "ms-resource:Appname" as the Package Display Name and the Application Display Name.

2. Create a ja-JP folder under strings, and add two resource files as follows:

   syntax

   ```
   strings\
       en-us\
       ja-jp\
           Resources.altform-msft-phonetic.resw
           Resources.resw
   ```

3. In Resources.resw for general ja-JP: Add a string resource for Appname "希蒼"

4. In Resources.altform-msft-phonetic.resw for Japanese furigana resources: Add furigana value for AppName "のあ"

The user can search for the app name "希蒼" using both the furigana value "のあ" (noa), and the phonetic value (using the **GetPhonetic** function from the Input Method Editor (IME)) "まれあお" (mare-ao).

Sorting follows the **Regional Control Panel** format:

- Under a Japanese user locale,
  - If furigana is enabled, then "希蒼" is sorted under "の".
  - If furigana is missing, then "希蒼" is sorted under "ま".
- Under a non-Japanese user locale,
  - If furigana is enabled, then "希蒼" is sorted under "の".
  - If furigana is missing, then "希蒼" is sorted under "漢字".

Design your app for bidirectional text

Article • 05/13/2022

Design your app to provide bidirectional text support (BiDi) so that you can combine script from right to left (RTL) and left to right (LTR) writing systems, which generally contain different types of alphabets.

Right-to-left writing systems, such as those used in the Middle East, Central and South Asia, and in Africa, have unique design requirements. These writing systems require bidirectional text support (BiDi). BiDi support is the ability to input and display text layout in either right to left (RTL) or left to right (LTR) order.

A total of nine BiDi languages are included with Windows.

- Two fully localized languages. Arabic, and Hebrew.
- Seven Language Interface Packs for emerging markets. Persian, Urdu, Dari, Central Kurdish, Sindhi, Punjabi (Pakistan), and Uyghur.

This topic contains the Windows BiDi design philosophy, and case studies that show BiDi design considerations.

Bidi design elements

Four elements influence BiDi design decisions in Windows.

- **User interface (UI) mirroring**. User interface (UI) flow allows right-to-left content to be presented in its native layout. UI design feels local to BiDi markets.
- **Consistency in user experience**. The design feels natural in right-to-left orientation. UI elements share a consistent layout direction and appear as the user expects them.
- **Touch optimization**. Similar to touch UI in non-mirrored UI, elements are easy to reach, and they natural to touch interaction.
- **Mixed text support**. Text directionality support enables great mixed text presentation (English text on BiDi builds, and vice versa).

Feature design overview

Windows supports the four BiDi design elements. Let's look at some of the major relevant features of (prior versions of) Windows, and provide some context around how they affect your app.

Navigate in the direction that feels natural

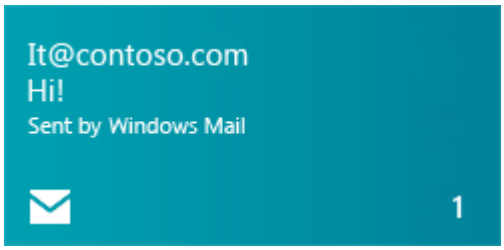
Windows adjusts the direction of the typographic grid so that it flows from right to left, meaning that the first tile on the grid is placed at the top right corner, and the last tile at the bottom left. This matches the RTL pattern of printed publications such as books and magazines, where the reading pattern always starts at the top right corner and progresses to the left.

To preserve a consistent UI flow, content on tiles retain a right-to-left layout, meaning that the app name and logo are positioned at the bottom right corner of the tile regardless of the app UI language.

BiDi tile

1 Notification Region
2 Notification Badge
3 App Name/Logo

English tile

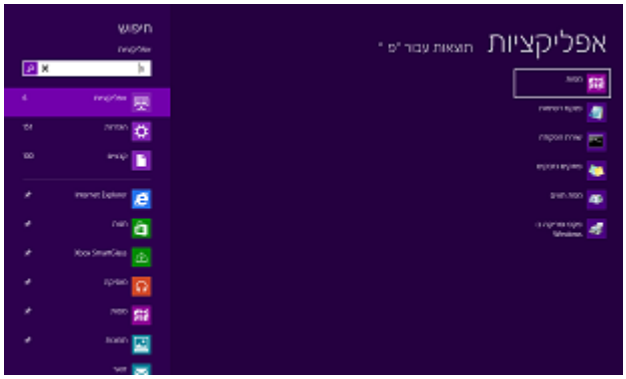


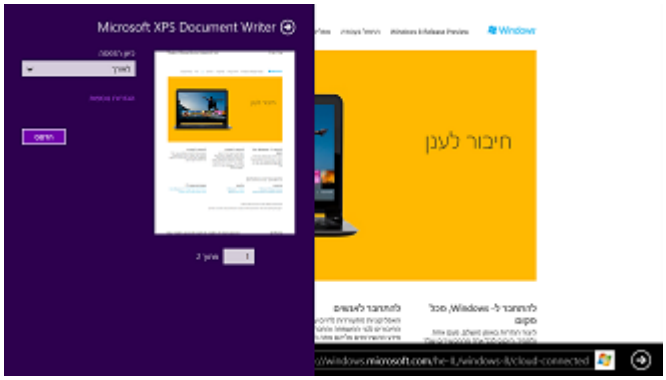
Get tile notifications that read correctly

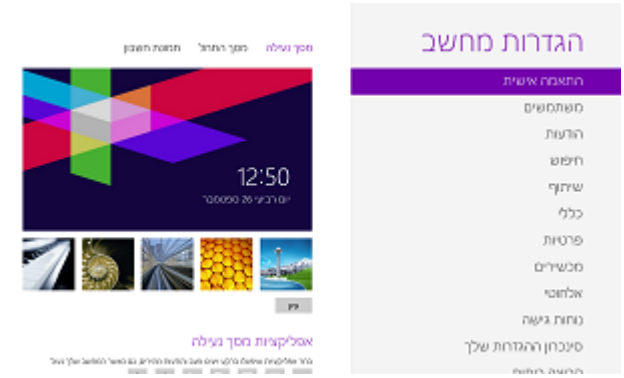
Tiles have mixed text support. The notification region has built-in flexibility to adjust the text alignment based on the notification language. When an app sends Arabic, Hebrew, or other BiDi language notifications, the text is aligned to the right. And when an English (or other LTR) notification arrives, it will align to the left.

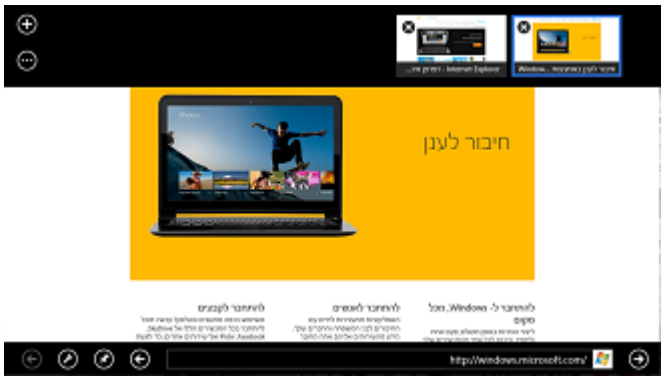
A consistent, easy-to-touch RTL user experience

Every element in the Windows UI fits into the RTL orientation. Charms and flyouts have been positioned on the left edge of the screen so that they don't overlap search results or degrade touch optimization. They can be easily reached with the thumbs.



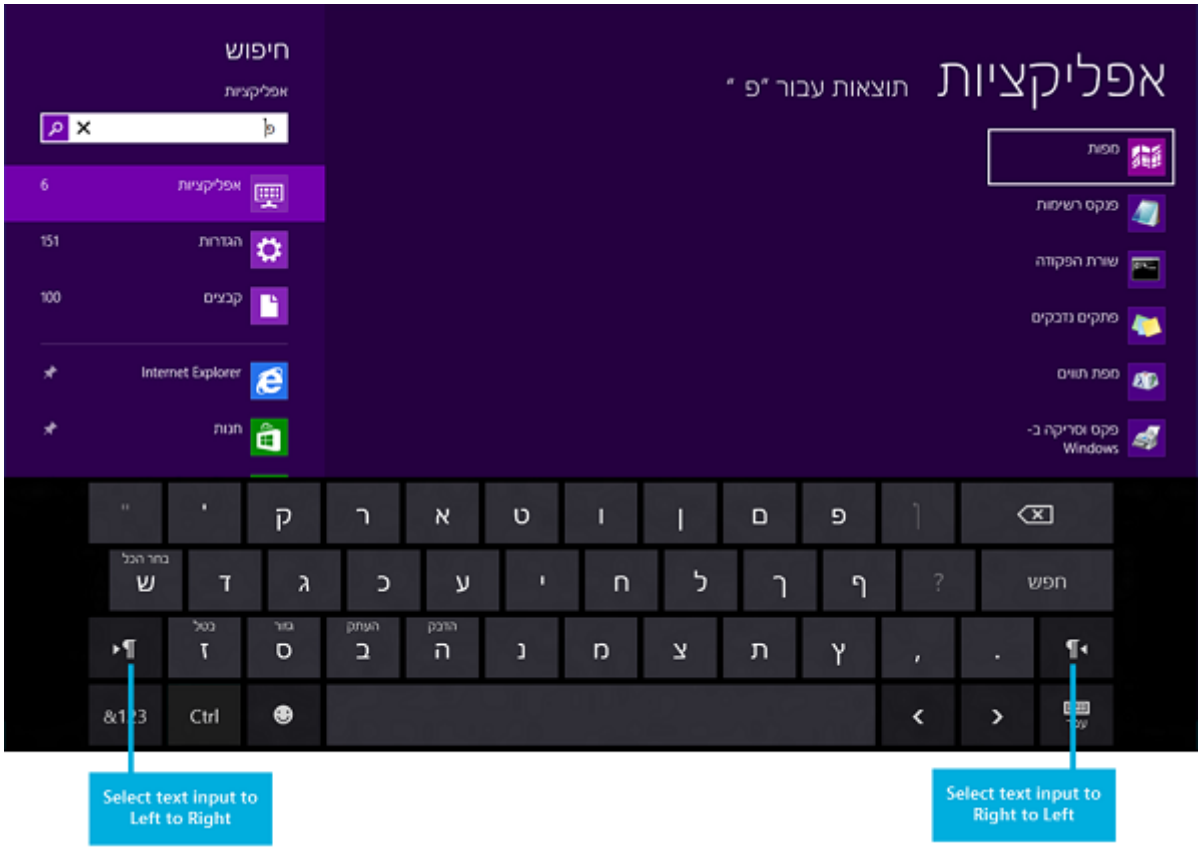






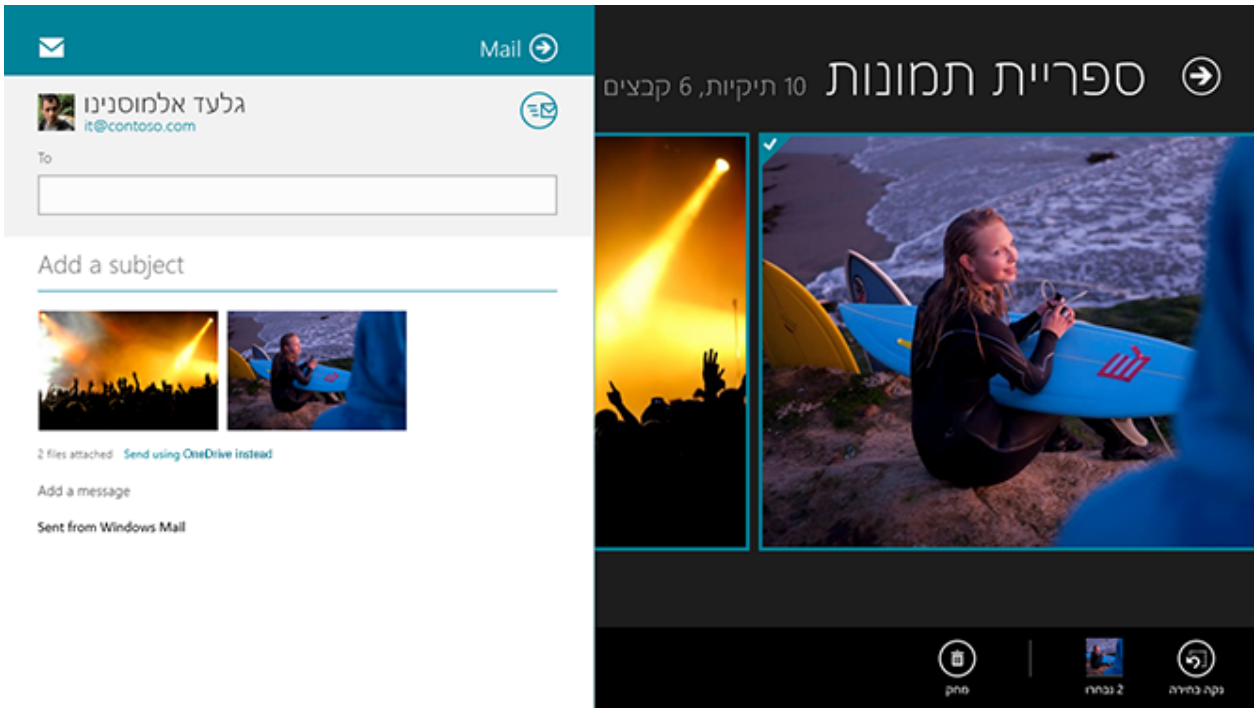
Text input in any direction

Windows offers an on-screen touch keyboard that is clean and clutter-free. For BiDi languages, there is a text direction control key so that the text input direction can be switched as needed.



Use any app in any language

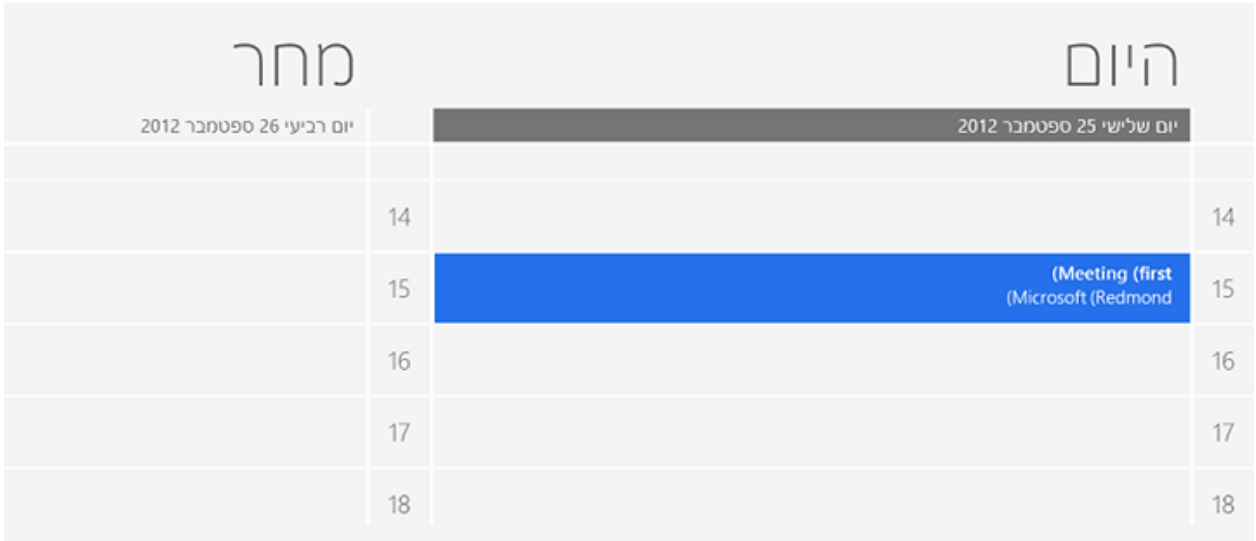
Install and use your favorite apps in any language. The apps appear and function as they would on non-BiDi versions of Windows. Elements within apps are always placed in a consistent and predictable position.



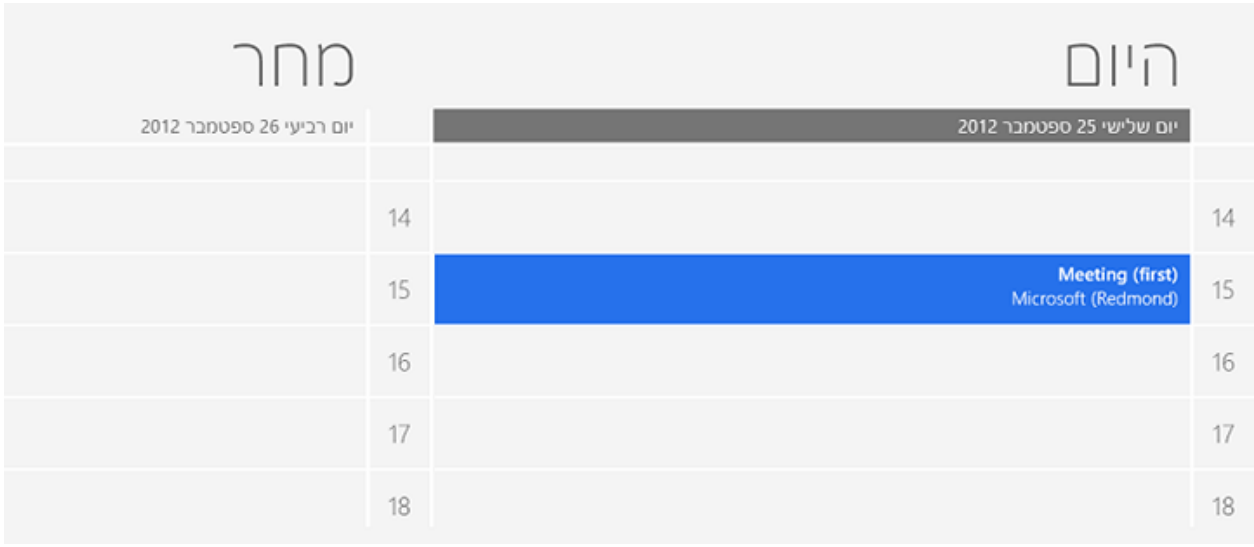
Display parentheses correctly

With the introduction of the BiDi Parenthesis Algorithm (BPA), paired parentheses always display properly regardless of language or text alignment properties.

Incorrect parentheses



Correct parentheses



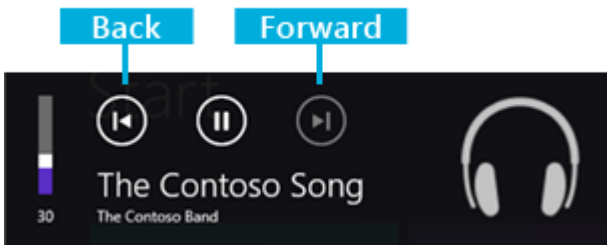
Typography

Windows uses the Segoe UI font for all BiDi languages. This font is shaped and scaled for the Windows UI.

Case study #1: A BiDi music app

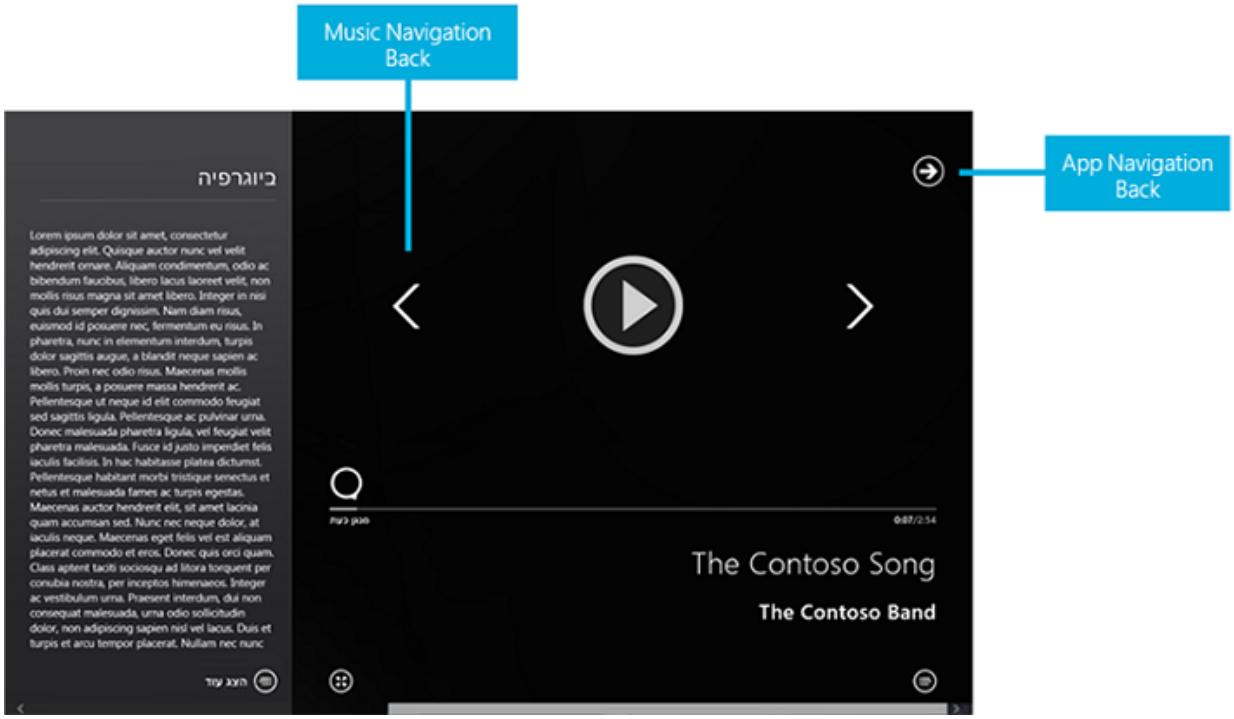
Overview

Multimedia apps make for a very interesting design challenge, because media controls are generally expected to have a left-to-right layout similar to that of non-BiDi languages.

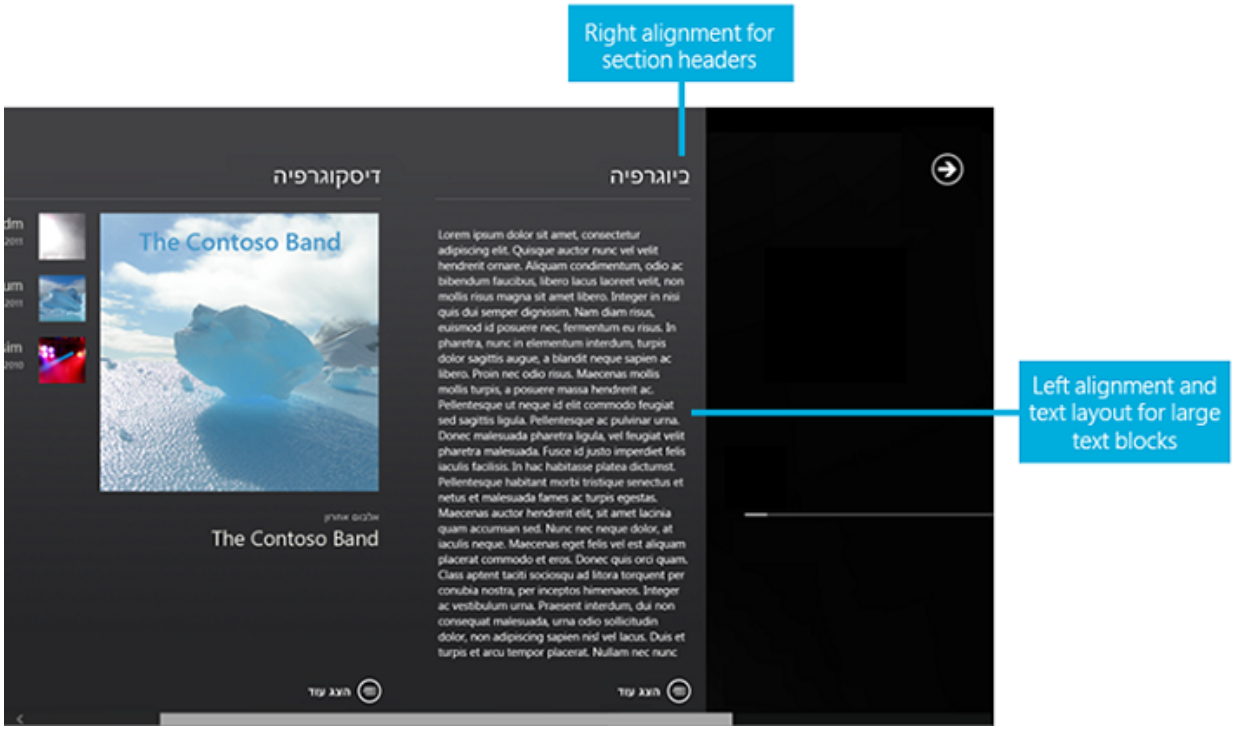


Establishing UI directionality

Retaining the right-to-left UI flow is important for consistent design for BiDi markets. Adding elements that have left-to-right flow within this context is difficult, because some navigational elements such as the back button may contradict the directional orientation of the back button in the audio controls.



This music app retains a right-to-left-oriented grid. This gives the app a very natural feel for users who already navigate in this direction across the Windows UI. The flow is retained by ensuring that the main elements are not just ordered from right to left, but also aligned properly in the section headers to help maintain the UI flow.



Text handling

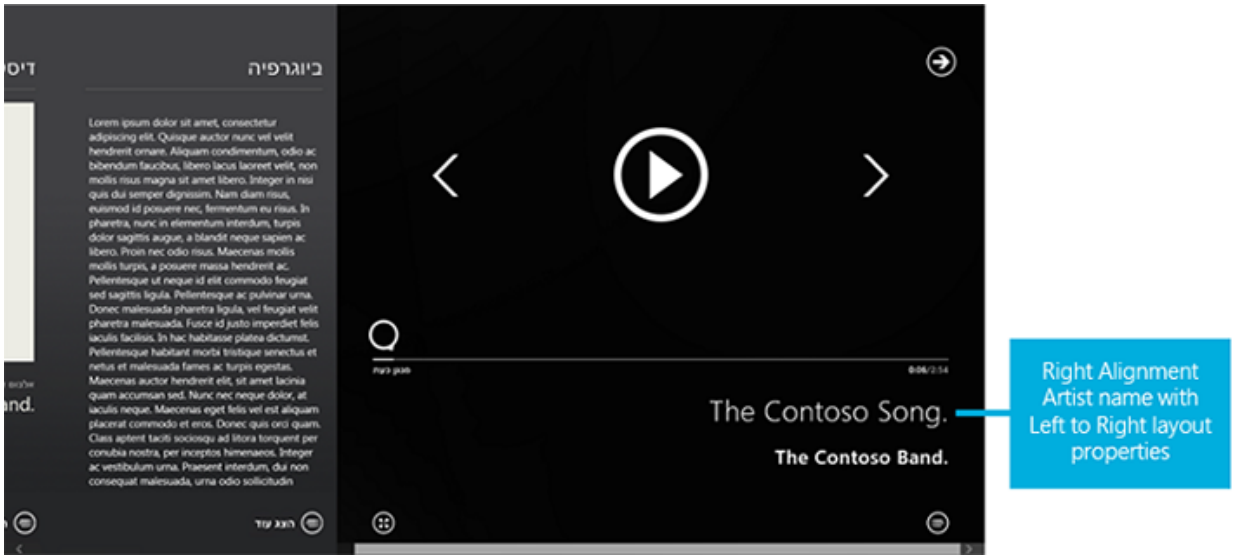
The artist bio in the screenshot above is left-aligned, while other artist-related text pieces such as album and track names preserve right alignment. The bio field is a fairly large text element, which reads poorly when aligned to the right simply because it's hard to track between the lines while reading a wider text block. In general, any text element with more than two or three lines containing five or more words should be considered for similar alignment exceptions, where the text block alignment is opposite to that of the overall app directional layout.

Manipulating the alignment across the app can look simple, but it often exposes some of the boundaries and limitations of the rendering engines in terms of neutral character placement across BiDi strings. For example, the following string can display differently based on alignment.

	English String (LTR)	**Hebrew String (RTL)**
Left-alignment	Hello, World!	!בוקר טוב
Right-alignment	!Hello, World	!בוקר טוב

To ensure that artist information is properly displayed across the music app, the development team separated text layout properties from alignment. In other words, the artist info might be displayed as right-aligned in many of the cases, but the string layout adjustment is set based on customized background processing. The background

processing determines the best directional layout setting based on the content of the string.



For example, without custom string layout processing, the artist name "The Contoso Band." would appear as ".The Contoso Band".

Specialized string direction preprocessing

When the app contacts the server for media metadata, it preprocesses each string prior to displaying it to the user. During this preprocessing, the app also does a transformation to make the text direction consistent. To do this, it checks whether there are neutral characters on the ends of the string. Also, if the text direction of the string is opposite to the app direction set by the Windows language settings, then it appends (and sometimes prepends) Unicode direction markers. The transformation function looks like this.

C#

```
string NormalizeTextDirection(string data)
{
    if (data.Length > 0) {
        var lastCharacterDirection =
DetectCharacterDirection(data[data.Length - 1]);

        // If the last character has strong directionality (direction is not
null), then the text direction for the string is already consistent.
        if (!lastCharacterDirection) {
            // If the last character has no directionality (neutral
character, direction is null), then we may need to add a direction marker to
            // ensure that the last character doesn't inherit directionality
from the outside context.
            var appTextDirection = GetAppTextDirection(); // checks the
<html> element's "dir" attribute.
            var dataTextDirection = DetectStringDirection(data); // Run
```

```
through the string until a non-neutral character is encountered,
                                                                    // which
determines the text direction.

            if (appTextDirection != dataTextDirection) {
                // Add a direction marker only if the data text runs
opposite to the directionality of the app as a whole,
                // which would cause the neutral characters at the ends to
flip.
                var directionMarkerCharacter =
                    dataTextDirection == TextDirections.RightToLeft ?
                        UnicodeDirectionMarkers.RightToLeftDirectionMarker :
// "\u200F"
                        UnicodeDirectionMarkers.LeftToRightDirectionMarker;
// "\u200E"

                data += directionMarkerCharacter;

                // Prepend the direction marker if the data text begins with
a neutral character.
                var firstCharacterDirection =
DetectCharacterDirection(data[0]);
                if (!firstCharacterDirection) {
                    data = directionMarkerCharacter + data;
                }
            }
        }
    }

    return data;
}
```

The added Unicode characters are zero-width, so they don't impact the spacing of the strings. This code carries a potential performance penalty, since detecting the direction of a string requires running through the string until a non-neutral character is encountered. Each character that's checked for neutrality is first compared against several Unicode ranges as well, so it isn't a trivial check.

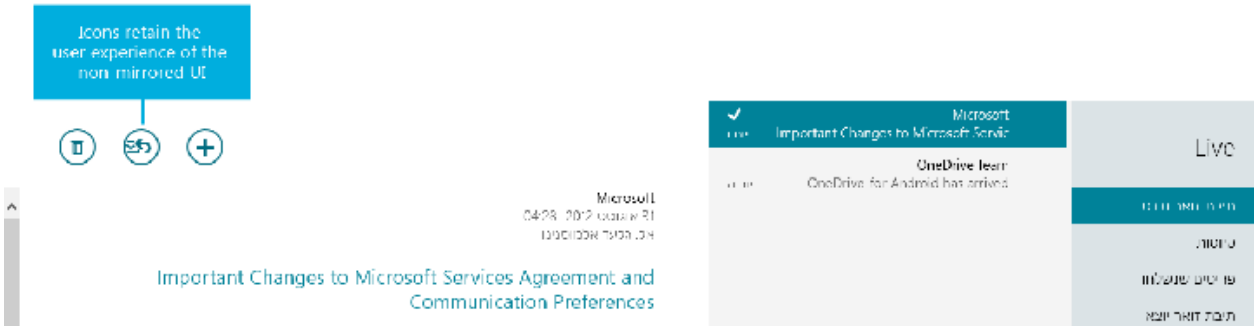
Case study #2: A BiDi mail app

Overview

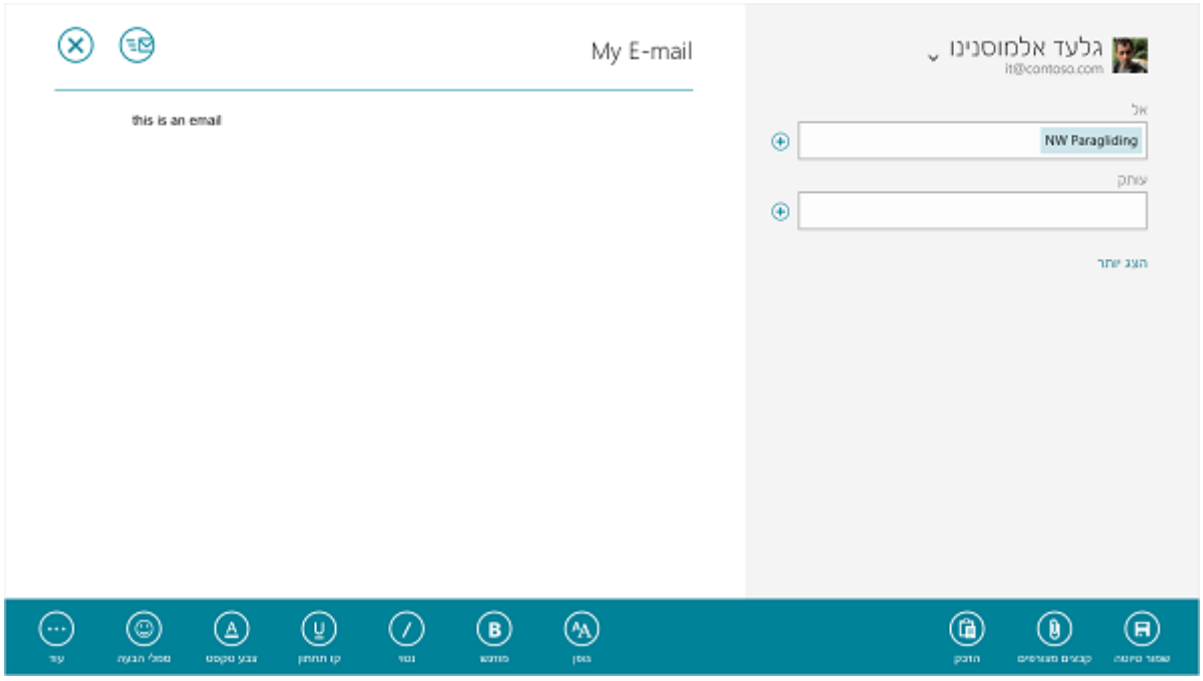
In terms of UI layout requirements, a mail client is fairly simple to design. The Mail app in Windows is mirrored by default. From a text-handling perspective the mail app is required to have more robust text display and composition capabilities in order to accommodate mixed text scenarios.

Establishing UI directionality

The UI layout for the Mail app is mirrored. The three panes have been reoriented so that the folder pane is positioned on the right edge of the screen, followed by the mail item list pane to the left, and then the email composition pane.



Additional items have been reoriented to match the overall UI flow, and touch optimization. These include the app bar and the compose, reply, and delete icons.



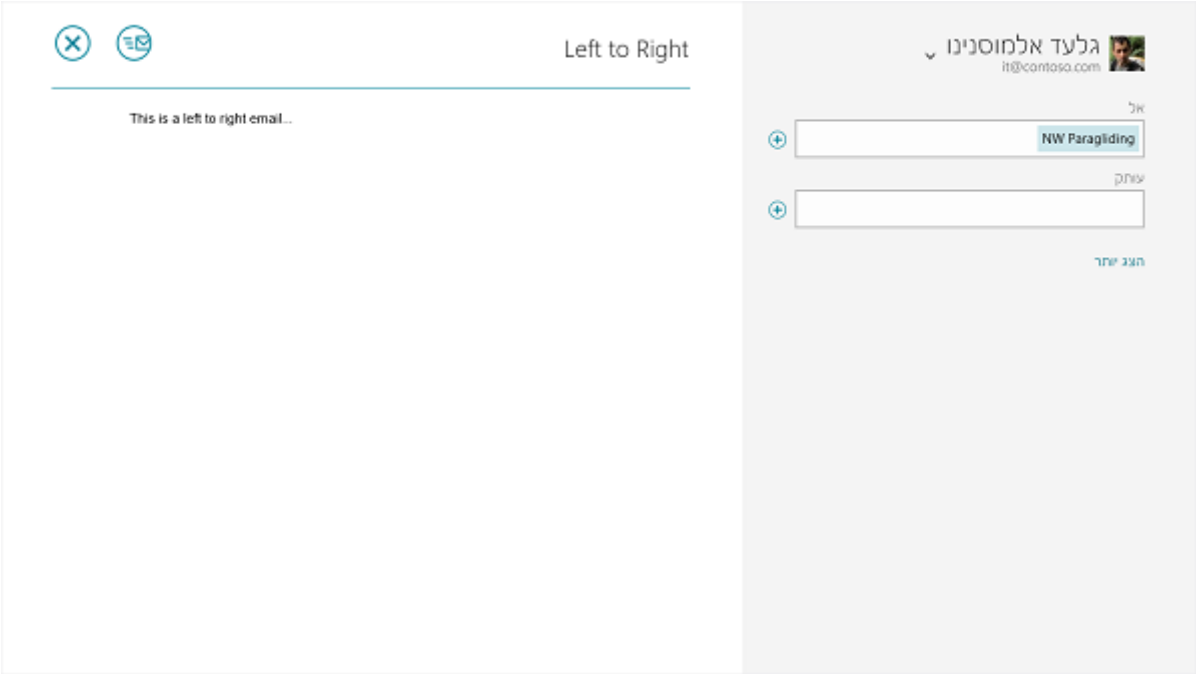
Text Handling

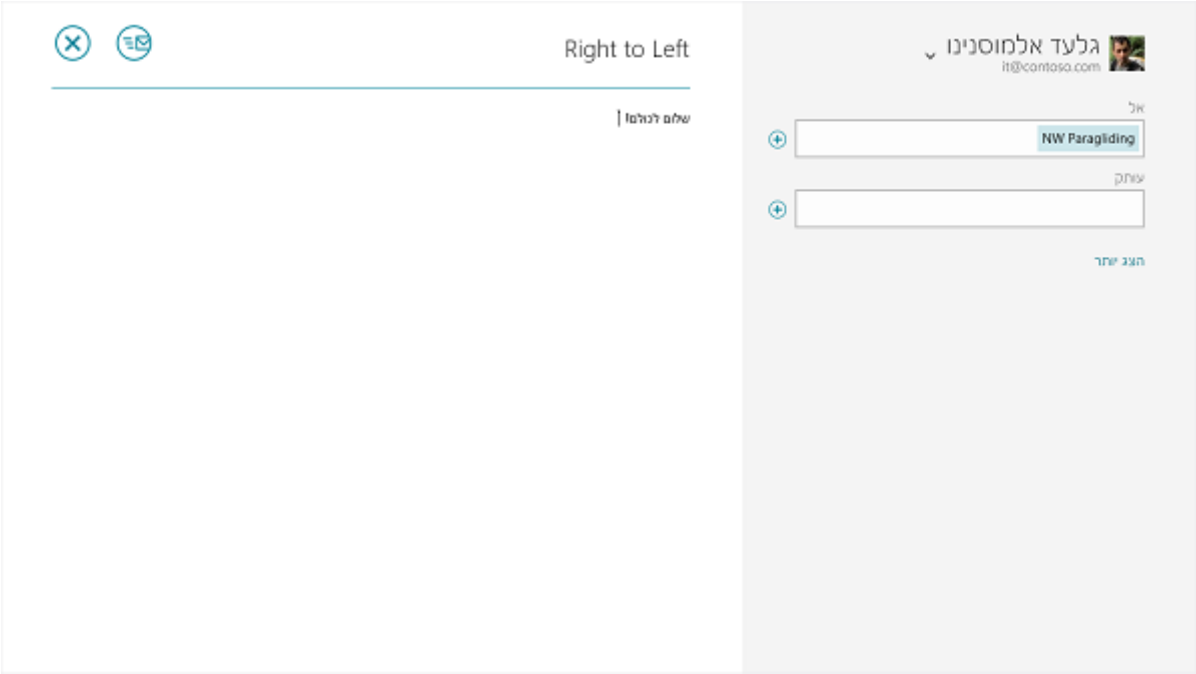
UI

Text alignment across the UI is usually right-aligned. This includes the folder pane and items pane. The item pane is limited to two lines of text (Address, and Title). This is important for retaining the right-to-left alignment, without introducing a block of text that would be difficult to read when the content direction is opposite to the UI direction flow.

Text Editing

Text editing requires the ability to compose in both right-to-left and left-to-right form. In addition, the composition layout must be preserved by using a format—such as rich text—that has the ability to save directional information.





Use UTF-8 code pages in Windows apps

Article • 08/20/2024

Use UTF-8 character encoding for optimal compatibility between web apps and other *nix-based platforms (Unix, Linux, and variants), minimize localization bugs, and reduce testing overhead.

UTF-8 is the universal code page for internationalization and is able to encode the entire Unicode character set. It is used pervasively on the web, and is the default for *nix-based platforms.

Set a process code page to UTF-8

As of Windows Version 1903 (May 2019 Update), you can use the ActiveCodePage property in the appxmanifest for packaged apps, or the fusion manifest for unpackaged apps, to force a process to use UTF-8 as the process code page.

> **Note**
>
> GDI doesn't currently support setting the ActiveCodePage property per process. Instead, GDI defaults to the active system codepage. To configure your app to render UTF-8 text via GDI, go to Windows **Settings** > **Time & language** > **Language & region** > **Administrative language settings** > **Change system locale**, and check **Beta: Use Unicode UTF-8 for worldwide language support**. Then reboot the PC for the change to take effect.

You can declare the ActiveCodePage property, and target/run on earlier Windows builds, but you must handle legacy code page detection and conversion as usual. With a minimum target version of Windows Version 1903, the process code page will always be UTF-8, so legacy code page detection and conversion can be avoided.

> **Note**
>
> In UTF-8, an encoded character is represented by a sequence of 1 to 4 bytes. (See definition D92 in Chapter 3 of The Unicode Standard for the formal specification.)

Examples

Appx manifest for a packaged app:

XAML

```
<?xml version="1.0" encoding="utf-8"?>
<Package
xmlns="http://schemas.microsoft.com/appx/manifest/foundation/windows10"
         ...

xmlns:uap7="http://schemas.microsoft.com/appx/manifest/uap/windows10/7"

xmlns:uap8="http://schemas.microsoft.com/appx/manifest/uap/windows10/8"
         ...
         IgnorableNamespaces="... uap7 uap8 ...">

  <Applications>
    <Application ...>
      <uap7:Properties>
        <uap8:ActiveCodePage>UTF-8</uap8:ActiveCodePage>
      </uap7:Properties>
    </Application>
  </Applications>
</Package>
```

Fusion manifest for an unpackaged Win32 app:

XAML

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<assembly manifestVersion="1.0" xmlns="urn:schemas-microsoft-com:asm.v1">
  <assemblyIdentity type="win32" name="..." version="6.0.0.0"/>
  <application>
    <windowsSettings>
      <activeCodePage
xmlns="http://schemas.microsoft.com/SMI/2019/WindowsSettings">UTF-
8</activeCodePage>
    </windowsSettings>
  </application>
</assembly>
```

> **Note**
>
> Add a manifest to an existing executable from the command line with `mt.exe -manifest <MANIFEST> -outputresource:<EXE>;#1`.

-A vs. -W APIs

Win32 APIs often support both -A and -W variants.

-A variants recognize the ANSI code page configured on the system and support `char*`, while -W variants operate in UTF-16 and support `WCHAR`.

Until recently, Windows has emphasized "Unicode" -W variants over -A APIs. However, recent releases have used the ANSI code page and -A APIs as a means to introduce UTF-8 support to apps. If the ANSI code page is configured for UTF-8, then -A APIs typically operate in UTF-8. This model has the benefit of supporting existing code built with -A APIs without any code changes.

Code page conversion

Because Windows operates natively in UTF-16 (`WCHAR`), you might need to convert UTF-8 data to UTF-16 (or vice versa) to interoperate with Windows APIs.

MultiByteToWideChar and WideCharToMultiByte let you convert between UTF-8 and UTF-16 (`WCHAR`) (and other code pages). This is particularly useful when a legacy Win32 API might only understand `WCHAR`. These functions allow you to convert UTF-8 input to `WCHAR` to pass into a -W API and then convert any results back if necessary.

Use `dwFlags` of either `0` or `MB_ERR_INVALID_CHARS` when using these functions with `CodePage` set to `CP_UTF8` (otherwise an `ERROR_INVALID_FLAGS` occurs).

> **Note**
>
> `CP_ACP` equates to `CP_UTF8` only if running on Windows Version 1903 (May 2019 Update) or above and the ActiveCodePage property described above is set to UTF-8. Otherwise, it honors the legacy system code page. We recommend using `CP_UTF8` explicitly.

Prepare your application for the Japanese era change

Article • 05/13/2022

> **Note**
>
> On April 1, 2019, the new era name was announced: Reiwa (令和). On April 25, Microsoft released packages for different Windows operating systems containing the updated registry key with the new era name. Update your device and check your registry to see if it has the new key, and then test your application. Check **this support article** to make sure your operating system should have received the updated registry key.

The Japanese calendar is divided into eras, and for most of the modern age of computing, we've been in the Heisei era; however, on May 1, 2019, a new era will begin. Because this is the first time in decades for an era to change, software that supports the Japanese calendar will need to be tested to ensure it will function properly when the new era begins.

In the following sections, you will learn what you can do to prepare and test your application for the upcoming new era.

> **Note**
>
> We recommend that you use a test machine for this, because the changes you make will impact the behavior of the entire machine.

Add a registry key for the new era

> **Note**
>
> The following instructions are meant for devices that have not yet been updated with the new registry key. First check if your device contains the new registry key, and if not, test using the following instructions.

It is important to test for compatibility problems before the era has changed, and you can do so now using the new era name. To do this, add a registry key for the new era using **Registry Editor**:

1. Navigate to **Computer\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Nls\Calendars\Japanese\Eras**.
2. Select **Edit** > **New** > **String Value**, and give it the name **2019 05 01**.
3. Right-click the key and select **Modify**.
4. In the **Value data** field, enter **令和_令_Reiwa_R** (you can copy and paste from here to make it easier).

See Era Handling for the Japanese Calendar to read more about the format for these registry keys.

On April 1, 2019, the new era name was announced. On April 25, an update with a new registry key for supported Windows versions containing the name was released, allowing you to validate that your application handles it properly. This update is being propagated to supported earlier releases of Windows 10, as well as Windows 8 and Windows 7.

You can delete your placeholder registry key once you're finished testing your application. This will ensure it doesn't interfere with the new registry key that will be added when Windows is updated.

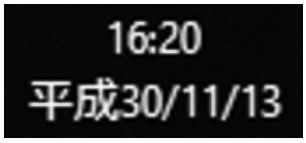
Change your device's calendar format

Once you've added the registry key for the new era, you need to configure your device to use the Japanese calendar. You don't need to have a Japanese-language device to do this. For thorough testing, you may want to install the Japanese language pack as well, but it isn't required for basic testing.

To configure your device to use the Japanese calendar:

1. Open **intl.cpl** (search for it from the Windows search bar).
2. From the **Format** dropdown, select **Japanese (Japan)**.
3. Select **Additional settings**.
4. Select the **Date** tab.
5. From the **Calendar type** dropdown, select **和暦** (*wareki*, the Japanese calendar). It should be the second option.
6. Click **OK**.
7. Click **OK** in the **Region** window.

Your device should now be configured to use the Japanese calendar, and it will reflect whichever eras are in the registry. Below is an example of what you might see now in the lower-right corner of the screen:



Adjust your device's clock

On Windows 10

1. Right-click the date and time area in the lower-right corner of the screen.
2. Select **Adjust date/time**.
3. In the Settings app, under **Change date and time**, select **Change**.
4. Change the date to on or after May 1, 2019.

On Windows 11

1. Right-click the date and time area in the lower-right corner of the screen.
2. Select **Adjust date/time**.

3. In the Settings app, under **Set the date and time manually**, select **Change**.
4. Change the date to on or after May 1, 2019.

> ⓘ **Note**
>
> You may not be able to change the date and time, when "Set time automatically" is "on".

> ⓘ **Note**
>
> You may not be able to change the date based on organization settings; if this is the case, talk to your admin. Alternatively, you can edit your placeholder registry key to have a date that has already passed.

Test your application

Now, test out how your application handles the new era. Check places where the date is displayed, such as timestamps and date pickers. Make sure that the era is correct before May 1, 2019 (Heisei, 平成) and after (Reiwa, 令和).

Gannen (元年)

The format for the Japanese calendar is generally **<Era name> <Year of era>**. For example, the year 2018 is **Heisei 30** (平成30年). However, the first year of an era is special; instead of being **<Era name> 1**, it is **<Era name> 元年** (*gannen*). So, the first year of the Heisei era would be 平成元年 (*Heisei gannen*). Make sure that your application properly handles the first year of the new era, and correctly outputs 令和元年.

Related APIs

There are several WinRT, .NET, and Win32 APIs that will be updated to handle the era change, so if you use them, you shouldn't have to worry too much. However, even if you do rely entirely on these APIs, it's still a good idea to test your application and make sure you get the desired behavior, especially if you are doing anything special with them like parsing.

You can follow along with updates to the OS and SDKs at Updates for May 2019 Japan Era Change.

The following APIs will be impacted:

WinRT

- Windows.Globalization Namespace
  - Calendar Class
    - AddDays Method
    - AddEras Method
    - AddHours Method

    - AddMinutes Method
    - AddMonths Method
    - AddNanoseconds Method
    - AddPeriods Method
    - AddSeconds Method
    - AddWeeks Method
    - AddYears Method
    - Era Property
    - EraAsString Method
    - FirstYearInThisEra Property
    - LastEra Property
    - LastYearInThisEra Property
    - NumberOfYearsInThisEra Property
- Windows.Globalization.DateTimeFormatting Namespace
  - DateTimeFormatter Class
    - Format Method

.NET

- System Namespace
  - DateTime Struct
  - DateTimeOffset Struct
- System.Globalization Namespace
  - Calendar Class
  - DateTimeFormatInfo Class
  - JapaneseCalendar Class
  - JapaneseLunisolarCalendar Class

Win32

- datetimeapi.h header
  - GetDateFormatA function
  - GetDateFormatEx function
  - GetDateFormatW function
- winnls.h header
  - EnumDateFormatsA function
  - EnumDateFormatsExA function
  - EnumDateFormatsExEx function
  - EnumDateFormatsExW function
  - EnumDateFormatsW function
  - GetCalendarInfoA function
  - GetCalendarInfoEx function
  - GetCalendarInfoW function

Learn about important Multilingual App Toolkit (MAT) news and updates here.

Multilingual App Toolkit 4.1

The Multilingual App Toolkit 4.1 update released.

MAT 4.1 audience

This extension is provided free to any Visual Studio developers interested in localizing their supported project types (such as UWP, WPF, VSIX, .NET for iOS/Mac/Android, and others).

What's new in MAT 4.1

- Visual Studio 2022 support.

MAT 4.1 Features

- **IDE and build integration**: End-to-end resource file localization. Translated resources are synchronized during builds.
- **Machine Translation**: Use Microsoft Translator and Language portal for translation.
- **Import/Export**: Recycle existing translations by importing .xlf files, or export machine translations for human review.

For more details, see Use the Multilingual App Toolkit.

Download MAT 4.1

Download the Multilingual App Toolkit 4.1 (VS 2022+) from the Visual Studio Marketplace.

Multilingual App Toolkit 4.1 Editor

Multilingual App Toolkit 4.1 Editor updates released.

MAT 4.1 Editor audience

The Multilingual App Toolkit Editor is a dedicated localization editor for human translators that, through its support for XLIFF, is not limited to any product or business category.

Although this editor is a part of the Multilingual App Toolkit and can be incorporated into workflows using the MAT Visual Studio extension, the use of Visual Studio is not a requirement. For example, this editor can be leveraged by Microsoft Dynamics 365 Translation Service (DTS) users to revise the output of machine translations produced by DTS.

What's new in the MAT 4.1 Editor

- Allow installation without Visual Studio as a pre-requisite.
- Allow users to configure MS Translator provider from the UI.
- Re-enable Language Portal as a translation provider.
- Redesign of telemetry collection to satisfy current compliance requirements.

For more details, see Multilingual App Toolkit Editor.

Download MAT 4.1 Editor

See Multilingual App Toolkit 4.1 Editor for language downloads.

Use the Multilingual App Toolkit

Article • 11/14/2022

The Multilingual App Toolkit (MAT) integrates with Microsoft Visual Studio to provide Windows apps with translation support, translation file management, and editor tools. Here are some of the value propositions of the toolkit.

- Helps you manage resource changes and translation status during development.
- Provides a UI for choosing languages based on configured translation providers.
- Supports the localization industry-standard XLIFF file format.
- Provides a pseudo-language engine to help identify translation issues during development.
- Connects with the Microsoft Language Portal to easily access translated strings and terminology.
- Connects with the Microsoft Translator for quick translation suggestions.

How to use the toolkit

Step 1. Design your app for globalization and localization

Before you can use the MAT effectively, your app needs to be localizable. Specifically, your project should contain one or more Resources Files (.resw) containing your app's strings in the default language. For details, see Localize strings in your UI and app package manifest. Once you've done that, the toolkit makes adding additional languages quick and easy.

For the value proposition of globalization and localization—as well as definitions of the terms **globalization**, **localizability**, and **localization**—see Globalization and localization.

Also see Guidelines for globalization and Make your app localizable.

Step 2. Download and install the Multilingual App Toolkit

There are two parts to the Multilingual App Toolkit (MAT), each with its own installer.

- Multilingual App Toolkit Extension for Visual Studio 2017-2019. This contains the MAT extension for Visual Studio 2019, in the form of a .vsix installer.
- Multilingual App Toolkit 4.1 Extension for Visual Studio 2022 and later. This contains the MAT 4.1 extension for Visual Studio 2022, in the form of a .vsix installer.

- Multilingual app toolkit Editor. This contains the MAT standalone Multilingual Editor tool, in the form of an .msi installer. It also includes the MAT extension for Visual Studio 2015 and for Visual Studio 2013.

If you use Visual Studio 2017 or later, then download and run both installers, one after the other. If you use Visual Studio 2015 or Visual Studio 2013, then download and run the .msi installer.

Step 3. Enable the Multilingual App Toolkit for your project

The MAT must be enabled for your project before you can begin to localize the app. Here's how to enable the toolkit.

- Open the project solution in Visual Studio.
- Select the desired project in Solution Explorer.
- On the **Tools** menu, select **Multilingual App Toolkit** > **Enable selection**.

In the Output window (showing output from Multilingual App Toolkit), watch for the message `Project '<project-name>' was enabled. The project's source culture is '<language-tag>' <language-name>`. If this message appears, then the MAT is ready to use.

Step 4. Add languages to your project

Follow these steps to add languages to your project.

1. Right-click the project node in Solution Explorer.
2. Click **Multilingual App Toolkit** > **Add translation languages...**.
3. In the Translation Languages dialog, select the language(s) you want to support, and click OK.

The toolkit does these things in response.

- For each language you added, a new folder is created named for the BCP-47 language tag of the language. Inside that folder, new Resources File(s) (.resw) are created to match the one(s) that contain the default language strings.
- If this is the first time you've added a language, a new folder named `MultilingualResources` is added to the project. Inside that folder, an .xlf file is added for each language. The .xlf files contain a translation unit for each string in each Resources File (.resw) in your project.
- The Output window confirms the addition of the language(s) that you added.

Whenever you add/remove a default language Resources File (.resw), or you add/remove a string inside a default language Resources File (.resw), rebuild the project to re-synchronize the .xlf files. This ensures that the .xlf files contain the union of the strings in the default language.

Installed Translation Providers—such as the Microsoft Language Portal and Microsoft Translator—can be used to translate your app's resources. When a provider supports a specific language, the provider's icon is displayed next to the language name in the Translation Languages dialog.

In the Translation Languages dialog, any existing .xlf-based languages that are discovered by the toolkit have their selection box pre-checked to indicate that the language is already included the project.

Once a language is added to the project, it cannot be removed by un-checking the box in the Translation Languages dialog. To remove a language, right-click on the language-specific .xlf file and select **Delete**. If you confirm, then this will also delete the corresponding Resources File (.resw).

Step 5. Test your app using pseudo language

Pseudo language is an artificial modification of the software product intended to simulate real language localization, but remaining readable to native speakers. Pseudo translation replaces characters and expands the resource string length to detect potential localizability issues or bugs early in the project cycle and before localization starts in earnest.

Follow these steps to pseudo-localize and test your project.

1. Use the Translation Languages dialog to add Pseudo Language (Pseudo) [qps-ploc] to your project.
2. Right-click the `<project-name>.qps-ploc.xlf` file in Solution Explorer and click **Multilingual App Toolkit** > **Generate machine translations**.
3. In **Settings** > **Time & Language** > **Region & language** > **Languages**, click **Add a language**.
4. In the search box, type `qps-ploc`.
5. Click `English (qps-ploc)` to add it.
6. From the language list, select `English (qps-ploc)` and click **Set as default**.
7. Test your pseudo-localized app. For example, look for UI layout issues where not all of a string is displayed (the string is truncated), or strings that are not translated (but instead hard-coded).

In addition to character replacement and expansion, the pseudo engine provides a unique tracking identifier for each resource. This tracker is prepended to the start of every string and enclosed within brackets `[xxxxx]`. You can use these trackers during visual UI inspection testing. They can help track down specific resources in the product, especially if multiple resources have similar or duplicate text.

In this "Hello, World!" text example, the pseudo translation expands to take about 30 percent more screen space, and then applies the resource tracker.

`"Hello World" -> "Ĥèĺļõ Ŵòŗłđ" -> "[!!_Ĥèĺļõ Ŵòŗłđ_!!]" -> "[hJ8s1][!!_Ĥèĺļõ Ŵòŗłđ_!!]"`

Step 6. Translate your app into selected languages

The Multilingual App Toolkit is integrated into the build process. During a build, updated strings are automatically added to each language .xlf file. After you've tested your app by using Pseudo language, there are three options to translate your app into other languages for release.

Option 1. Translate the strings yourself

You can use the Multilingual Editor to translate strings individually. As already mentioned, this is included in The .msi installer.

- Right-click the .xlf file that you want to translate.
- Click **Open With...** and select Multilingual Editor. You can optionally click **Set as Default**.
- For each string, **Source** shows the original string in the default language. In **Translation**, type the string translated into the appropriate language for the .xlf file that you're editing.
- When you're done, save and close the file.

Rebuild your project to cause the translated strings to be copied into the Resources File (.resw) that corresponds to the .xlf file you were just editing.

You can also launch the Multilingual Editor like this. Go to Start, show all apps, open the Multilingual App Toolkit folder, and click Multilingual Editor to launch it.

Option 2. Send the .xlf files to a third party for translation

To outsource the translation and editing work to localizers, select the desired .xlf files in Solution Explorer, right-click them, and click **Multilingual App Toolkit** > **Export**

translations....

Select **Output: Mail recipient** in the Export string resources dialog, and click OK, and your files will be zipped and attached to a new email. Select **Output: File folder location**, browser for a folder and click OK, optionally choose for the files to be zipped, click OK again, and your files will be (zipped and) saved at the location you chose, inside a new folder named for your project.

After your localizers complete the translation work and send you the translated .xlf files, you can import them into your project. Select the desired .xlf files in Solution Explorer, right-click them, and click **Multilingual App Toolkit** > **Import/recycle translations...**. Click **Add**, navigate to the .xlf or .zip files, and click **Import**.

Note The import process performs basic validation before importing. This ensures that the target culture information in the files being imported matches that in the existing .xlf files.

Rebuild your project to cause the translated strings to be copied into the Resources File(s) (.resw) that corresponds to the .xlf file(s) you just imported.

These third party providers offer localization services, and may be able to assist you.

- Elanex
- Keywords Studios
- Lionbridge
- Moravia
- SDL
- Welocalize

> **Note**
>
> The list above is provided for informational purposes only and is not an endorsement. Microsoft does not make any representation or warranty regarding these vendors or their services, and under no circumstances will Microsoft have any liability for your use of such vendors or services. Any questions, complaints, or claims regarding such vendors or their services must be directed to the appropriate vendor.

Option 3. Use the integrated translation services

Translation services are integrated into the Visual Studio IDE as well as into the Multilingual Editor. This provides easy access to translation services while developing

your product as well as localizing your resources. For this service, you'll need an Azure account subscription, as described in Microsoft Translator Moves to the Azure portal.

To access the translation services inside Visual Studio, select and right-click one or more .xlf files in Solution Explorer and click **Generate machine translations**.

The Multilingual Editor provides the same translation support, as well as adding interactive translation suggestions, which enable you to select the translation that best fits your resource strings. After the translation suggestion is provided, you can fine-tune the string for your translation style.

Two providers are shipped with the Multilingual App Toolkit.

- The Microsoft Language Portal provider enables translation-recycling and terminology-matching support based on translations of the user interface text for Microsoft products and services.
- The Microsoft Translator provider enables on-demand machine translation services.

You and your translator(s) can manage the status of translations in the Multilingual Editor to review uncertain translations later. You can set the status of each string in the **Properties** tab. Status values are: **New**, **Needs review**, **Translated**, **Final**, and **Signed off**. The indicator at the left of the row shows the status. When all rows show green in the Multilingual Editor, then your translation work is done.

Rebuild your project to cause the translated strings to be copied into the Resources File(s) (.resw) that corresponds to the .xlf file(s) you just edited.

Step 7. Upload your app to the Microsoft Store

Before you start the Microsoft Store Certification process, you must exclude the `<project-name>.qps-ploc.xlf` file from your project. Pseudo language is used to detect potential localizability issues or bugs, but it is not a valid Microsoft Store language. If it is not removed then your app will fail during the Microsoft Store Certification process.

Multilingual App Toolkit Editor

Article • 11/14/2022

Use the standalone **Multilingual App Toolkit Editor** to help you localize your apps with localization file management, translation support, and editing tools.

Each of the following downloads contain an .msi installer for the Multilingual App Toolkit Editor (also known as the Multilingual Editor). The installer is available in 11 languages, please select the link for your preferred language.

- To start the installation immediately, click **Run**.
- To save the download to your computer for installation at a later time, click **Save**.

Spanish

Italian

> **Important**
>
> If using Visual Studio, you should also download and install **Multilingual App Toolkit Visual Studio 2017-2019** or **Multilingual App Toolkit Visual Studio 2022+**.

Overview

The Multilingual Editor helps create simpler translation workflows by focusing on the following areas:

- Use to easily edit translated strings.
- Get translations and suggestions quickly via the integrated Microsoft Language Portal and the Microsoft Translator services (requires an active Internet connection).
- Narrow down on the desired translation units by filtering on text and states.
- You can also quickly edit data stored in XLIFF files by adjusting pseudo and actual translations.

Installation requirements

> **ⓘ Important**
>
> Ensure you have the latest service pack and critical updates for your installed versions of Windows and Visual Studio.

- **Supported operating systems**: Windows 10 or later (x86 and x64)
- **Disk space requirements**: 6 MB (x86 and x64)

Additional info

- You must have an active Internet connection to use the Microsoft Language Portal and Microsoft Translator services.
- Microsoft Translator requires a subscription key for the Microsoft Translator Text API.

Multilingual App Toolkit FAQ & troubleshooting

FAQ

This topic provides answers to frequently-asked questions and issues related to the Multilingual App Toolkit (MAT).

Also see Use the Multilingual App Toolkit.

Note The toolkit supports both .resw (XAML) and .resjson (JavaScript) files. But in this topic we'll refer only to .resw files. A .resw file is known as a Resources File. It contains strings, either in the default language or translated into another language. The folder that contains a .resw file is typically named for the value of a language tag.

Do I need .resw files in multiple languages?

No. One of the key benefits of the Toolkit is that .resw files in multiple languages are not required. The Toolkit manages and synchronizes your app's resources by using .xlf files. This removes the challenges associated with keeping content synchronized across multiple .resw files.

Projects that contain matching .resw and .xlf files cause the translations from the .xlf file to be ignored. When this happens, a warning is displayed during the build to let you know that the .xlf translations are not included in the final app. A .resw file and .xlf file match when they have a target language with the same language code. An example of a matching pair would be `Strings\de-DE\Resources.resw` and an `<project-name>.de-DE.xlf` file (containing `target-language="de-DE"`).

Can I have .resw files in multiple languages?

You can, but we don't recommend it. If you want to include .resw files in multiple languages in your project and use the Toolkit, make sure you don't have matching .resw and .xlf files.

I don't see an option in the Tools menu to enable the Multilingual App Toolkit

Try these steps.

- Make sure you select the project node, not the solution node, before opening the **Tools** menu.
- Confirm that the toolkit extension is installed by using the Visual Studio Extension Manager.
- Confirm that your project is a UWP project.

When I build my project, I don't see a message saying that a Multilingual App Toolkit build has started

Confirm that you've enabled the MAT for your project. On the **Tools** menu, select **Multilingual App Toolkit** > **Enable selection**. If your project was enabled with a previous version, then disable and re-enable the MAT by using the **Tools** menu. This updates the project to work with the new version of the Toolkit.

Ensure that the "Build Task for all Visual Studio editions" component was installed. This build component is installed with the extension, but it can be manually deselected during the installation. This component is required to update the .xlf files and add the translation into the PRI file. When this component is installed and working correctly, you will see these build messages.

dosbatch

```
1> Multilingual App Toolkit build started.
1> Multilingual App Toolkit build completed successfully.
```

The toolkit is reporting that it didn't locate any XLIFF language files during the build

dosbatch

```
No XLIFF language files were found. The app will not contain any localized
resources.
```

This message is displayed when the toolkit doesn't find any files in the project with an extension of .xlf. The toolkit generates and keeps these files in the `MultilingualResources` folder by default. They can be moved; but it's best to leave them in that folder because that allows the Multilingual Editor to locate the related metadata files.

My .xlf file is not included in the list of files processed by the toolkit during build

If you manually exclude an .xlf file from the project, and then re-include it, the file type element may not be set correctly. In Visual Studio, select the file and check the Properties window. The file's Build Action should be set to XliffResource and Copy to Output Directory should be set to Do not copy. This is how the reference should look in your project file.

XML

```
<XliffResource Include="MultilingualResources\<project-name>.fr-FR.xlf" />
```

I've added .xlf-based languages. Where are my strings?

Your default language Resources File (.resw) is your canonical "schema" of the strings that your app uses. Translated Resources Files can contain all, or a subset of, these strings.

When you build your project, your Resources Files and your .xlf files are synchronized.

- The .xlf files are updated to reflect any added or removed string, or added or removed Resources Files.
- The Resources Files are updated to reflected any translated strings in the .xlf files.

This is explained in detail in Use the Multilingual App Toolkit.

When I build my project, the .xlf files remain empty

Before you can use the MAT effectively, your app needs to be localizable. This is explained in detail in Use the Multilingual App Toolkit.

What is Microsoft Translator?

Microsoft Translator is a cloud-based service that provides machine-based translation. Machine translation is ideal for gaining access to translation when human translation is not reasonable to obtain. You can learn more at Microsoft Translator.

The Toolkit uses the Microsoft Translator service to provide translation suggestions to you. You can see which languages are supported by Microsoft Translator when the Microsoft Translator icon is present in the Translation Languages dialog.

You can quickly translate your app using Microsoft Translator from within the Multilingual Editor by selecting a string and clicking **Translate**.

What is pseudo language, and what are pseudo resource trackers?

Pseudo language is an artificial modification of the software product intended to simulate real language localization. You can find more details about pseudo language and pseudo resource trackers in Use the Multilingual App Toolkit.

How do I set my language preference to pseudo language, so that I can test my pseudo-loc'd strings?

This is explained in Use the Multilingual App Toolkit.

What kind of localizability issues can I find using pseudo language?

This is explained in Use the Multilingual App Toolkit.

I'm not seeing any translations when I launch my app, or my app is only partially translated

Open the .xlf file in the Multilingual Editor to see whether the translations are present. When strings in the default language .resw file are changed explicitly, any corresponding translations are removed from .xlf files. This is to ensure that a translation matches its source string. Translate the string(s) in the .xlf file(s), and rebuild to update the non-default language .resw file(s).

If your strings are translated in the .xlf file(s), but they're not appearing in your app, then rebuild your project to update the non-default language .resw file(s). Visual Studio optimizes the Build command to build only files that have changed since the last Build.

Check your language preference order. Ensure that the language you want to test is listed at the top of your language preference list in **Settings**.

The toolkit is reporting error 0x80004004 in the build output

```dosbatch
Merge of Loc PRI file failed calling makepri.exe: "0x80004004"
```

This message can be displayed when the region format conflicts with the toolkit build operation. The workaround is to change your language in **Settings** to en-US while building.

The toolkit is reporting error 0x80004005 in the build output

```dosbatch
Merge of Loc PRI file failed calling makepri.exe: "0x80004005"
```

This message can be displayed when the .xlf file contains an unsupported target language. For example, "zh-cht" is incorrect (change it to "zh-hant"), and "zh-chs" is

incorrect (change it to "zh-hans").

Is there a way to find out more information about the errors I'm seeing?

Yes, you can turn on verbose logging in Visual Studio. Click **Tools** > **Options** > **Projects and Solutions** > **Build and Run**. Change **MSBuild project build output verbosity** from Minimal to Normal or higher.

Running MSBuild from the command line can also produce additional messages.

```dosbatch
msbuild /t:rebuild <project-name>
```

Import translation failed

The import process performs basic validation before importing. This ensures that the target culture information in the files being imported matches that in the existing .xlf files. Open the .xlf files in the Multilingual Editor and make sure that the culture information matches.

What if my translator doesn't have Windows 10, Windows 11 and/or Visual Studio and/or the Multilingual App Toolkit installed?

When you select **Output: Mail recipient** in the Export string resources dialog, the email includes a link to download and install the Multilingual App Toolkit (MAT). Your translator can still install the MAT standalone Multilingual Editor tool even without Windows 10, Windows 11 nor Visual Studio.

For more details, see Use the Multilingual App Toolkit.

What happened to the `MarkupRules.xml` and `ResourcesLocks.xml` files?

The Multilingual App Toolkit doesn't use proprietary resource locking files. Instead, the XLIFF 1.2 tag `<mrk>` is added directly to the .xlf file to identify strings that are not modified during Machine Translation. This enables the XLIFF file to be self-contained, and allows for per-file based resource locking.

These extra support files are no longer needed and you can safely delete them if you have them.

What happened to the .tpx file?

The .tpx file provided an easy way to include the `MarkupRules.xml` and `ResourcesLocks.xml` files when the .xlf file was sent out for translation. This functionality is no longer required.

If you have translations in a .tpx file that you need to retrieve, simply rename the .tpx file extension to .zip. This will allow you to open and extract the contents with File Explorer or any .zip compatible tool.

I think I've done everything right, but it still isn't working

Try these steps.

1. Add translations using one of the methods already described.
2. Dump the .pri file (see MakePri.exe command-line options) to see whether your translations are in the .pri file. Translations will appear with language code and translated value like this.

```xml
<Candidate qualifiers="Language-QPS-PLOC" type="String">
    <Value>[!!_Ŝéãřćĥ_!!]</Value>
</Candidate>
```

3. Build from a Command Prompt; the resulting error may have more details than what is reported in the build output.

My app failed certification to the Microsoft Store

Before you start the Microsoft Store Certification process, you must exclude the `<project-name>.qps-ploc.xlf` file from your project. Pseudo language is used to detect potential localizability issues or bugs, but it is not a valid Microsoft Store language. If it is not removed then your app will fail during the Microsoft Store Certification process.

What data are you collecting?

The Multilingual App Toolkit Visual Studio (MAT VS) extension collects anonymous usage data and sends it to Microsoft servers to help improve our products and services. Telemetry is off by default and can be enabled or disabled at any time.

Usage data: This is anonymous information about what features are being used. For example: adding a new language to a MAT-enabled solution.

Configuration data: This is anonymous information regarding the version of MAT VS installed on and the version of Windows it is being run on.

Below is a concrete example of the data collected in the following format, Key / Value / Notes:

- AddLanguage / MachineID: xxxx / This is based on a hash of the network adapter NIC. It is not guaranteed to be unique.
- TimeStamp / 2022/01/07T22:04:45.0000000Z / Time event took place.
- MAT_Version / 4.1.02 / Version of MAT installed.
- Languages / fr,es,de/DE / List of languages added to project.

All data is collected using Application Insights and sent to Azure Log analytics. Data is retained for 90 days then deleted.

Guidelines for app help

Article • 06/24/2021

Applications can be complex, and providing effective help for your users can greatly improve their experience. Not all applications need to provide help for their users, and what sort of help should be provided can vary greatly, depending on the application.

If you decide to provide help, follow these guidelines when creating it. Help that isn't helpful can be worse than no help at all.

Intuitive Design

As useful as help content can be, your app cannot rely on it to provide a good experience for the user. If the user is unable to immediately discover and use the critical functions of your app, the user will not use your app. No amount or quality help will change that first impression.

An intuitive and user-friendly design is the first step to writing useful help. Not only does it keep the user engaged for long enough for them to use more advanced features, but it also provides them with knowledge of an app's core functions, which they can build upon as they continue to use the app and learn.

General instructions

A user will not look for help content unless they already have a problem, so help needs to provide a quick and effective answer to that problem. If help is not immediately useful, or if help is too complicated, then users are more likely to ignore it.

All help, no matter what kind, should follow these principles:

- **Easy to understand:** Help that confuses the user is worse than no help at all.
- **Straightforward:** Users looking for help want clear answers presented directly to them.
- **Relevant:** Users do not want to have to search for their specific issue. They want the most relevant help presented straight to them (this is called "Contextual Help"), or they want an easily navigated interface.
- **Direct:** When a user looks for help, they want to see help. If your app includes pages for reporting bugs, giving feedback, viewing term of service, or similar

functions, it is fine if your help links to those pages. But they should be included as an afterthought on the main help page, and not as items of equal or greater importance.

- **Consistent:** No matter the type, help is still a part of your app, and should be treated as any other part of the UI. The same design principles of usability, accessibility, and style which are used throughout the rest of your app should also be present in the help you offer.

Types of help

There are three primary categories of help content, each with varying strengths and suitable for different purposes. Use any combination of them in your app, depending on your needs.

Instructional UI

Normally, users should be able to use all the core functions of your app without instruction. But sometimes, your app will depend on use of a specific gesture, or there may be secondary features of your app which are not immediately obvious. In this case, instructional UI should be used to educate users with instructions on how to perform specific tasks.

See guidelines for instructional UI

In-app help

The standard method of presenting help is to display it within the application at the user's request. There are several ways in which this can be implemented, such as in help pages or informative descriptions. This method is ideal for general-purpose help, that directly answers a user's questions without complexity.

See guidelines for in-app help

External help

For detailed tutorials, advanced functions, or libraries of help topics too large to fit within your application, links to external web pages are ideal. These links should be used sparingly if possible, as they remove the user from the application experience.

See guidelines for external help

Instructional UI guidelines

Article • 06/24/2021

In some circumstances it can be helpful to teach the user about functions in your app that might not be obvious to them, such as specific touch interactions. In these cases, you need to present instructions to the user through the user interface (UI), so that they can use those features they might have missed.

When to use instructional UI

Instructional UI has to be used carefully. When overused, it can be easily ignored or annoy the user, causing it to be ineffective.

Instructional UI should be used to help the user discover important and non-obvious features of your app, such as touch gestures or settings they may be interested in. It can also be used to inform users about new features or changes in your app that they might have otherwise overlooked.

Unless your app is dependent on touch gestures, instructional UI should not be used to teach users the fundamental features of your app.

Principles of writing instructional UI

Good instructional UI is relevant and educational to the user, and enhances the user experience. It should be:

- **Simple:** Users don't want their experience to be interrupted with complicated information
- **Memorable:** Users don't want to see the same instructions every time they attempt a task, so instructions need to be something they'll remember.
- **Immediately relevant:** If the instructional UI doesn't teach a user about something that they immediately want to do, they won't have a reason to pay attention to it.

Avoid overusing instructional UI, and be sure to choose the right topics. Do not teach:

- **Fundamental features:** If a user needs instructions to use your app, consider making the app design more intuitive.
- **Obvious features:** If a user can figure out a feature on their own without instruction, then the instructional UI will just get in the way.
- **Complex features:** Instructional UI needs to be concise, and users interested in complex features are usually willing to seek out instructions and don't need to be

given them.

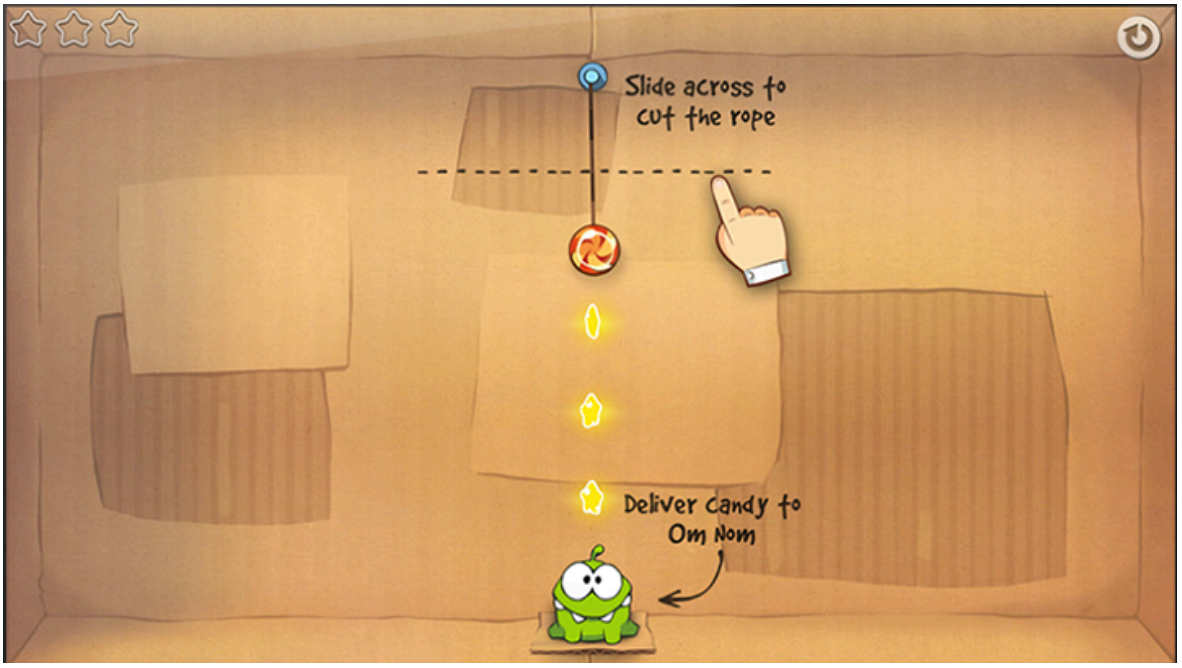
Avoid inconveniencing the user with your instructional UI. Do not:

- **Obscure important information:** Instructional UI should never get in the way of other features of your app.
- **Force users to participate:** Users should be able to ignore instructional UI and still progress through the app.
- **Displaying repeat information:** Don't harass the user with instructional UI, even if they ignore it the first time. Adding a setting to display instructional UI again is a better solution.

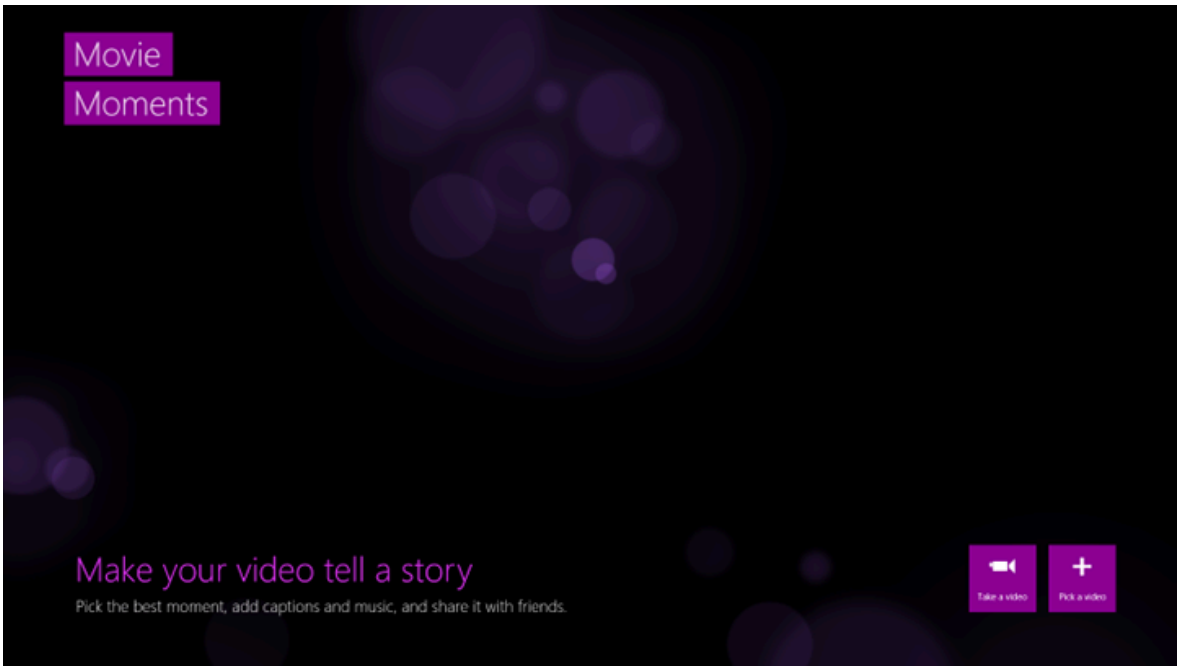
Examples of instructional UI

Here are a few instances in which instructional UI can help your users learn:

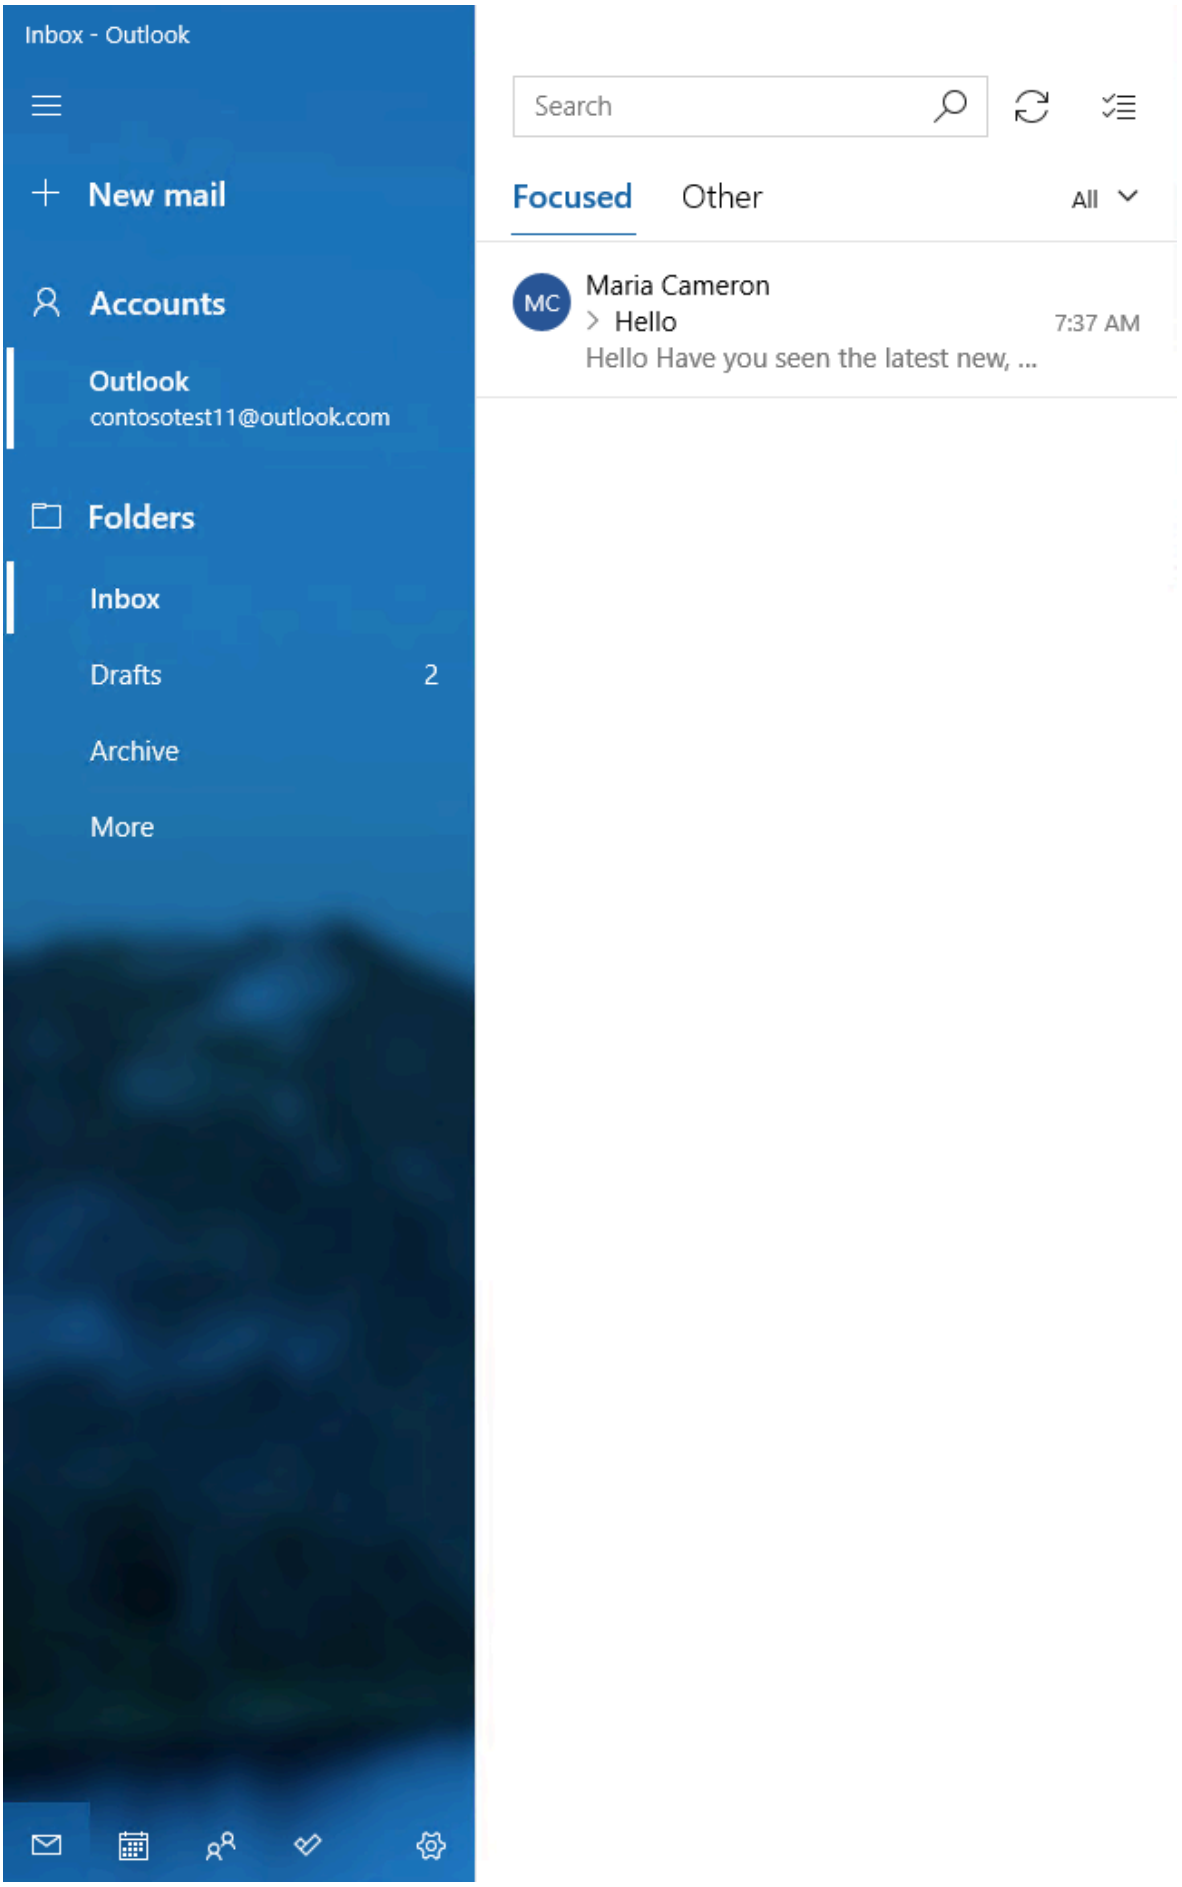
- **Helping users discover touch interactions.** The following screen shot shows instructional UI teaching a player how to use touch gestures in the game, Cut the Rope.



- **Making a great first impression.** When Movie Moments launches for the first time, instructional UI prompts the user to begin creating movies without obstructing their experience.



- **Guiding users to take the next step in a complicated task.** In the Windows Mail app, a hint at the bottom of the Inbox directs users to **Settings** to access older messages.



When the user clicks the message, the app's **Settings** flyout appears on the right side of the screen, allowing the user to complete the task. These screen shots show the Mail app before and after a user clicks the instructional UI message.

In-app help pages

Article • 06/24/2021

Most of the time, it is best that help be displayed within the application and when the user chooses to view it.

When to use in-app help pages

In-app help should be the default method of displaying help for the user. It should be used for any help which is simple, straightforward, and does not introduce new content to the user. Instructions, advice, and tips & tricks are all suitable for in-app help.

Complex instructions or tutorials are not easy to reference quickly, and they take up large amounts of space. Therefore, they should be hosted externally, and not incorporated into the app itself.

Users should not have to seek out help for basic instructions or to discover new features. If you need to have help that educates users, use instructional UI.

Types of In-app help

In-app help can come in several forms, though they all follow the same general principles of design and usability.

Help Pages

Having a separate page or pages of help within your app is a quick and easy way of displaying useful instructions.

- **Be concise:** A large library of help topics is unwieldy and unsuited for in-app help.
- **Be consistent:** Make sure that users can reach your help pages the same way from any part of your app. They should never have to search for it.
- **Users scan, not read:** Because the help a user is looking for might be on the same page as other help topics, make sure they can easily tell which one they need to focus on.

Popups

Popups allow for highly contextual help, displaying instructions and advice that is relevant to the specific task that the user is attempting.

- **Focus on one issue:** Space is even more restricted in a popup than a help page. Help popups needs to refer specifically a single task to be effective.
- **Visibility is important:** Because help popups can only be viewed from one location, make sure that they're clearly visible to the user without being obstructive. If the user misses it, they might move away from the popup in search of a help page.
- **Don't use too many resources:** Help shouldn't lag or be slow-loading. Using videos or audio files or high resolution images in popups is more likely to frustrate the user than it is to help them.

Descriptions

Sometimes, it can be useful to provide more information about a feature when a user inspects it. Descriptions are similar to instructive UI, but the key difference is that instructional UI attempts to teach and educate the user about features that they don't know about, whereas detailed descriptions enhance a user's understanding of app features that they're already interested in.

- **Don't teach the basics:** Assume that the user already knows the fundamentals of how to use the item being described. Clarifying or offering further information is useful. Telling them what they already know is not.
- **Describe interesting interactions:** One of the best uses for descriptions is to educate the user on how a features that they already know about can interact. This helps users learn more about things they already like to use.
- **Stay out of the way:** Much like instructional UI, descriptions need to avoid interfering with a user's enjoyment of the app.

- Guidelines for app help

External help pages

Article • 06/24/2021

If your app requires detailed help for complex content, consider hosting these instructions on a web page.

When to use external help pages

External help pages are less convenient for general use or quick reference. They are suitable for help content that is too extensive to be incorporated into the app itself, as well as for tutorials and instructions for advanced functions of an app that won't be used by its general audience.

If your help content is brief or specific enough to be displayed in-app, you should do so. Do not direct users outside of the app for help unless it is necessary.

Navigating external help pages

When a user is directed to an external help page, follow one of two scenarios:

- They are linked directly to the page that corresponds with their known issue. This is contextual help, and should be used when possible.
- They are linked to a general help page, with a clear display of categories and subcategories to choose from.

Providing users with a way to search your help can be useful, but do not make this search the only way of navigating your help. It can sometimes be difficult for users to describe their problems, which can make searching difficult. Users should be able to quickly find pages relevant to their problems without needing to search.

Tutorials and detailed walkthroughs

External help pages are the ideal place to provide users with tutorials and walkthroughs, whether video or textual.

- Tutorials should focus on more complicated ideas and advanced functions. Users shouldn't need a tutorial to use your app.
- Make sure that these tutorials are displayed differently from standard help instructions. Users who are looking for advanced instructions are more eager to search for them than users who want straightforward solutions to their problems.

- Consider linking to tutorials from both a directory and from individual help pages that correspond to each tutorial.

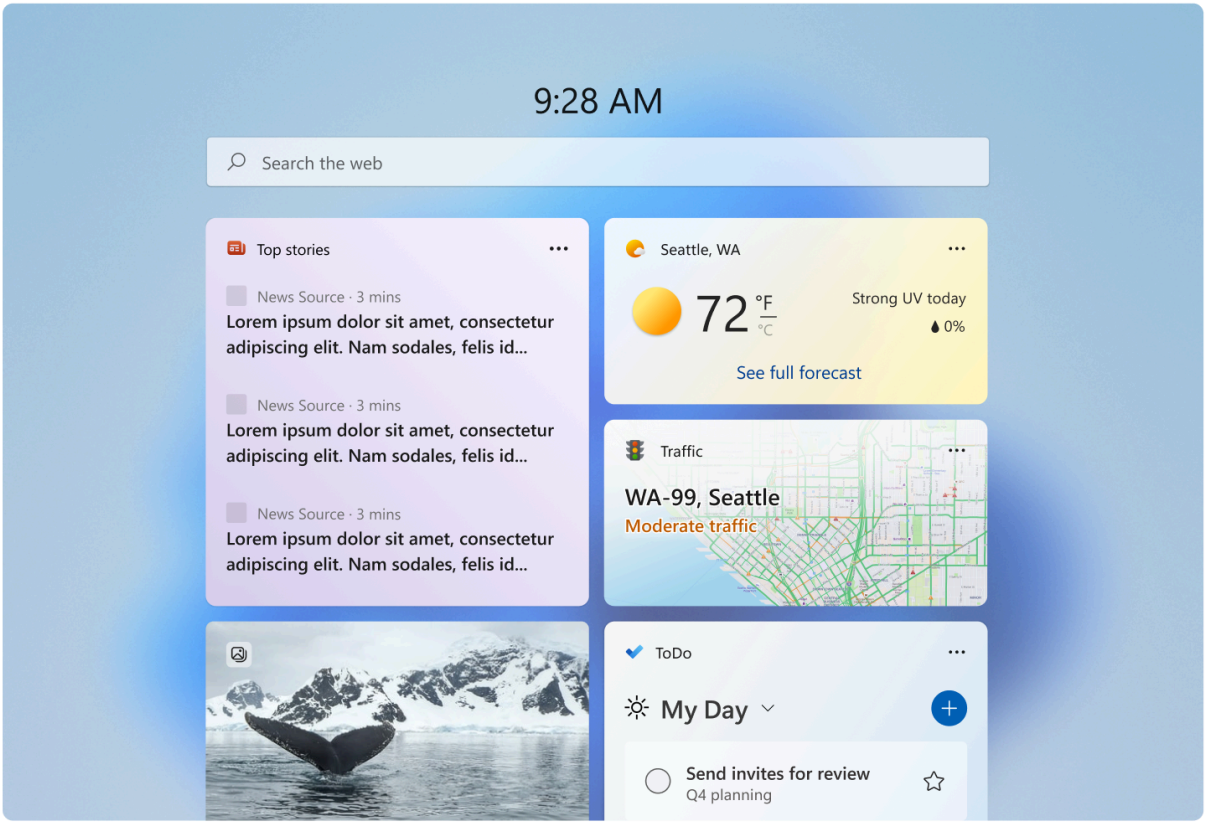
Widgets overview

Article • 03/09/2023

Windows Widgets are small UI containers that display text and graphics, associated with an app installed on the device. Installed widgets are displayed in a grid in the Widgets Board: a flyout plane that overlays the Windows desktop when the user clicks Widgets icon on the taskbar, uses the Windows+W shortcut, or swipes from the left edge of the screen. Widgets help people stay on top of what's important to them by aggregating personalized content and quick actions from the apps they use. They are quickly consumable and actionable. Widgets are not meant to replace apps and websites, but rather provide frictionless access to most-needed information or often-used functionalities that people can read/trigger right away. When designing your widget, consider the kind of value it will bring to your consumers.



Widgets terminology

Expand table

Term	Definition
Widgets host	An application that displays and manages Windows widgets. In the current release, the only Widgets host is the Widgets Board built into Windows 11.

Term	Definition
Widgets Board	The Widgets Board is a Windows 11 system component that is displayed over the desktop when the user clicks the Widgets icon on the taskbar, uses the Windows+W shortcut, or swipes from the left edge of the screen. The Widgets Board displays widgets and manages their layout the on the board.
Widget	A widget is an Adaptive Card that presents important content or actions from an app. It allows users to access desired information instantly without the need to launch the associated app or website. Widget content is refreshed dynamically throughout the day to provide the user with current and interesting content that can be consumed at a glance. Widgets provide basic interactive features that allow the user to launch the associated app for deeper engagement. Widgets are not intended to replace apps and websites.
Widget provider	A widget provider is a Windows app that provides content to be displayed in the widget. The widget provider owns the content, layout, and interactive elements of the widget.

Widget design guidance

The visual experience of a widget includes visual elements and interaction elements that are defined using the Adaptive Cards JSON format. The Adaptive Cards Designer provides a real-time editor for designing adaptive cards as well as templates for the supported widget sizes and themes. It's important that your widget's design adhere the Windows Widget design principles to help ensure that the Widgets Board provides a consistent and familiar experience for all widgets.

For a high-level walkthrough of the visual elements of a widget see Widget states and built-in UI components.

Widget principles

To create great Windows Widgets, consider the following principles as you design and develop your widgets:

Glanceable

Users can take a quick peek to get the most value out of the widget. They only need to click on it if they want richer details or deeper interactions.

Dependable

Surface frequently used information instantly to save users time in repeating those steps. Drive consistent re-engagement to your app.

Useful

Elevate the most useful and relevant information.

Personal

Provide personalized content and build an emotional connection with customers. Widgets should never contain ads. Customers are in control of their widget content and layout.

Focused

Each widget should generally focus on one main task or scenario. Widgets are not intended to replace your apps and websites.

Fresh

Content should dynamically refresh based on available context. It is up to date and provides the right content at the right time.

Planning your app's widget experience

1. Based on your understanding of your customers, identify the most important content or most useful actions that your users would love to have quick access to without opening your app or website. Consider the principles enumerated in the Widget principles section and think about how they can apply to your app.
2. Your app can support multiple individual widgets. Determine the number of separate widgets you want to support so that each widget focuses on a specific purpose.
3. Determine the content you want to include for each widget. A single widget can support three different sizes; small, medium, and large. For each widget, think about what content would bring the most value to users and your business needs. For each size from small to large, the purpose of the widget should remain the same, but the amount of information displayed should expand with larger sizes. We recommend that widget providers implement all widget sizes to give users flexibility when customizing the widget layout.

4. Think about the user interactions your widget will support. Users can click on the widget title or any click targets that you've defined on the widget. These interactions can activate deep-link shortcuts into your app or web site that take users directly to what they're interested in, so that they don't have to navigate from the root of your app. Consider the different navigational models offered.
5. Apps must implement a widget provider that implements the back-end functionality to send your widget's layout and data to the widgets board to be displayed. Currently you can implement a widget provider using a packaged Win32 desktop app or a Progressive Web App (PWA). For more information on creating a Win32 widget provider, see Widget service providers. For information on PWA widget providers, see Build PWA-driven widgets.

Widgets provide three sizes for the user to choose from. It is recommended that you create and consider all 3 sizes and adapt your design specifically for each size. Small and medium sizes provide better discoverability as they get surfaced more often within the dynamic feed. Large sizes are useful for displaying more in-depth information. Supporting multiple sizes allows flexibility in users customizing the widgets they choose to pin to the widgets board.

Small

The widget principles *glanceable* and *focused* become more important in design decisions made for the small size widget. The small size widget should not try to force all of the functionality that could comfortably fit in a large widget. Focus on one user interaction or piece of key information that can be surfaced here with 1 touch target.

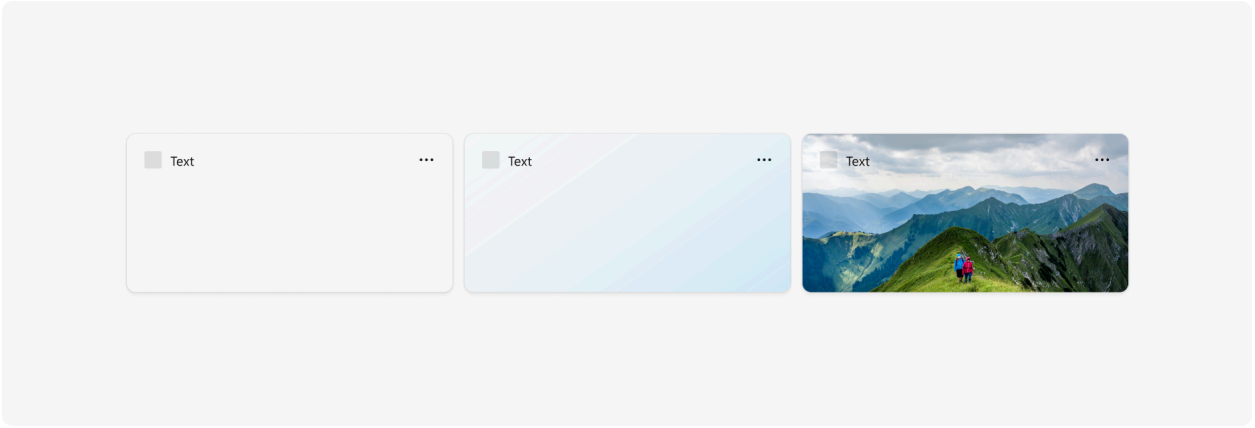
Medium

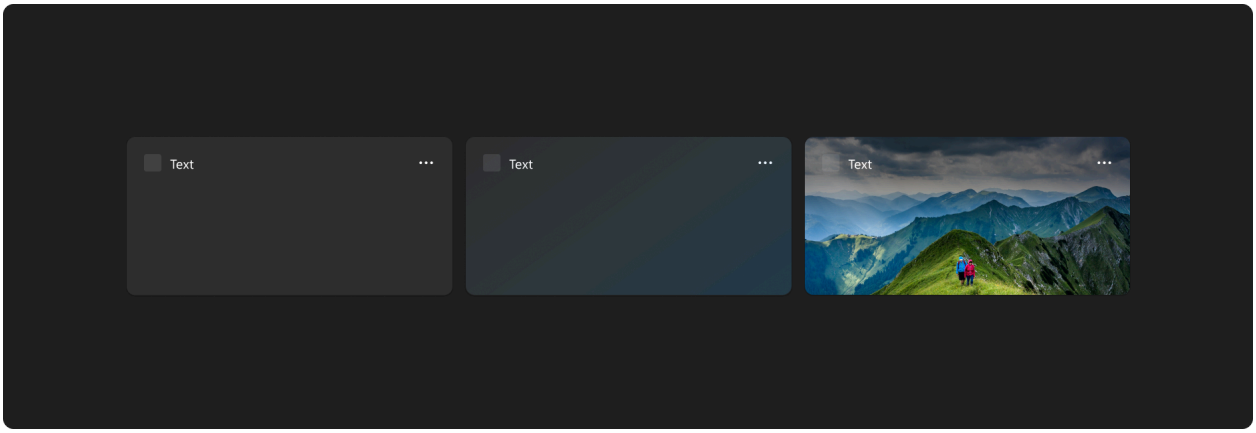
The medium size widget allows more room compared to the small, and so more functionality or additional information can be included. The medium widget could also provide the same focused experience as the small widget, but provide 2-3 touch targets.

Large

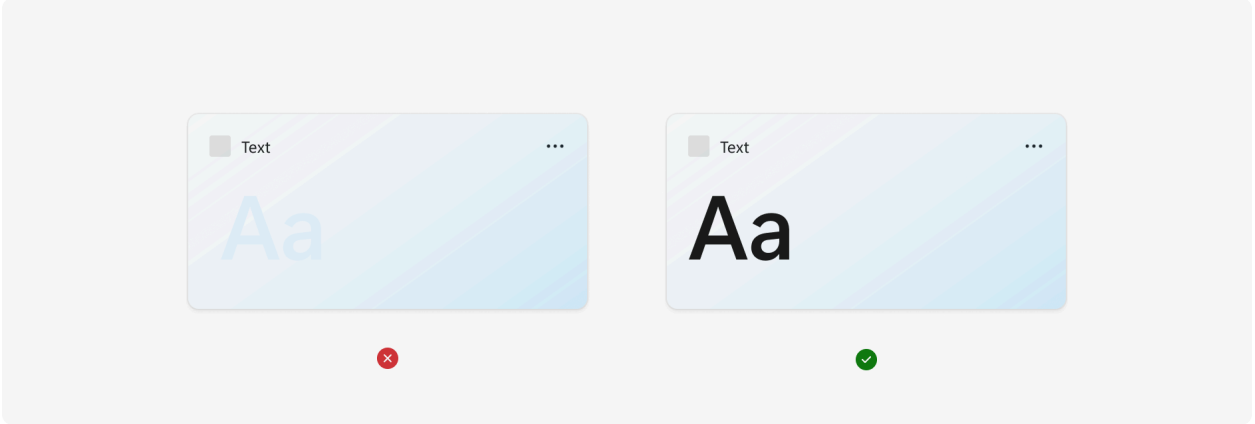
Large sizes allow for more information to be presented, but the content should still be focused and easily consumable. Alternatively, a large size card could highlight one image or topic and have a more immersive experience. The large size should have no more than 3-4 touch targets.

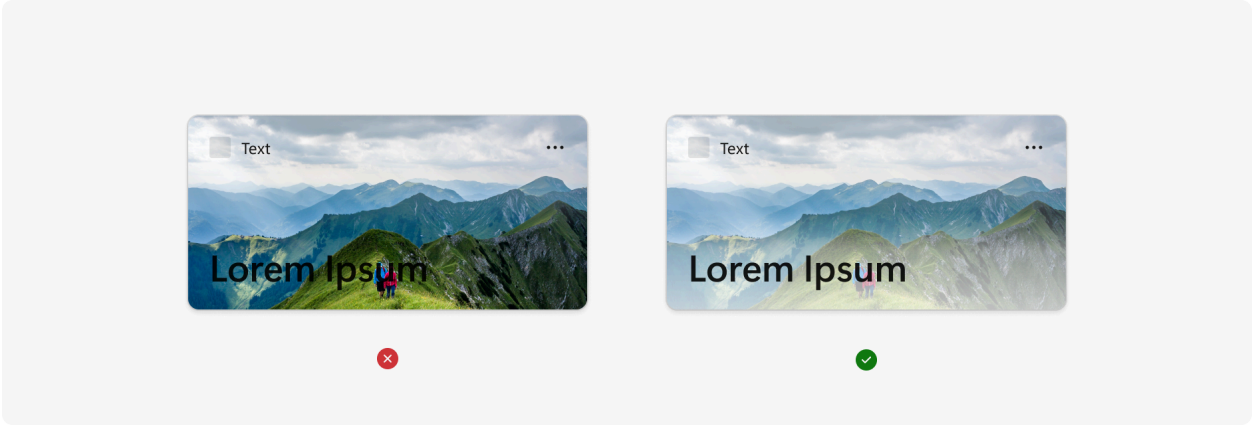
Color and theming





Windows 11 supports two color modes: light and dark. Each mode consists of a set of neutral color values that are automatically adjusted to ensure optimal contrast. For each widget size you support, make sure to create separate designs for light and dark themes so that the widget integrates seamlessly within the wider operating system and user's theme choice. The widget background supports customization with either a solid light/dark background, gradient tint, or image background.

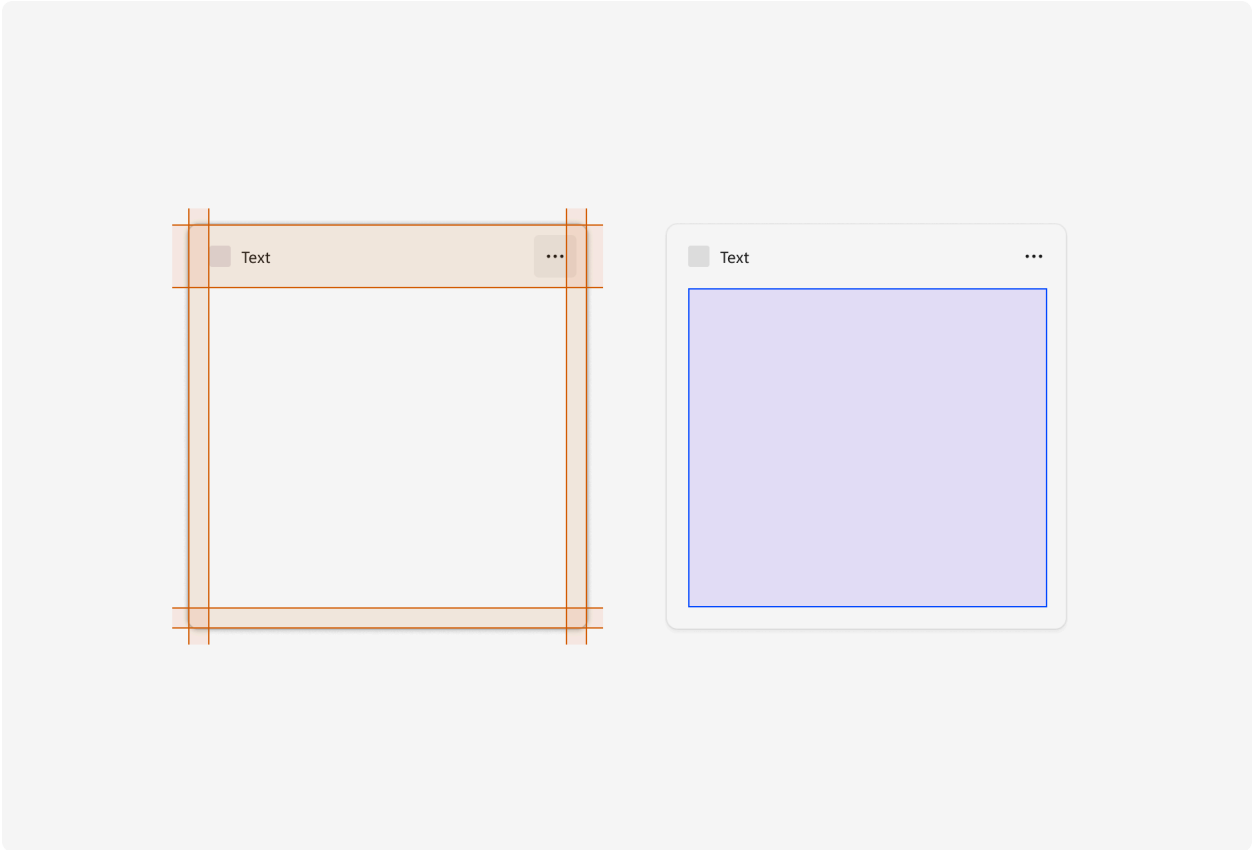




When choosing background colors, images, and content, make sure that there is enough color contrast to ensure legibility and accessibility.

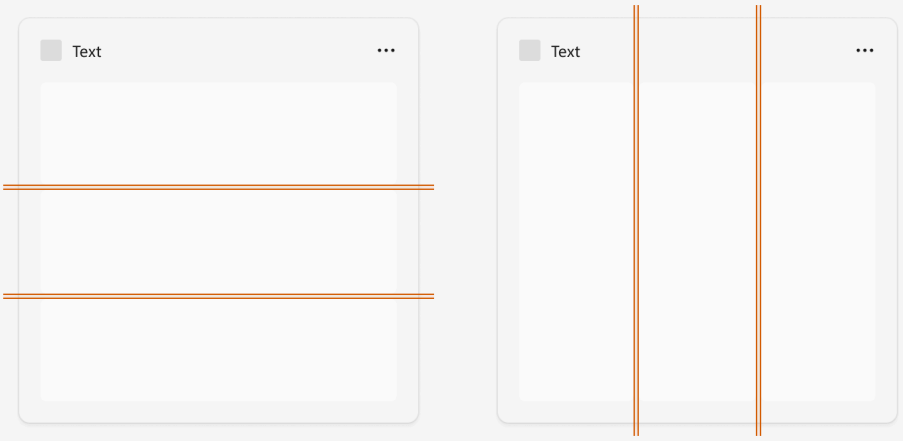
The Web Content Accessibility Guidelines (WCAG) 2.0 level AA requires a contrast ratio of at least 4.5:1 for normal text and 3:1 for large text. WCAG 2.1 requires a contrast ratio of at least 3:1 for graphics and user interface components (such as form input borders). WCAG Level AAA requires a contrast ratio of at least 7:1 for normal text and 4.5:1 for large text. Large text is defined as 14 point (typically 18.66px) and bold or larger, or 18 point (typically 24px) or larger.

Margins



Each widget has a 16px margin around it and a 48px Attribution area in which content cannot be placed. The only component that can live in the right side margin and bottom

margin are the pagination dots. For examples of the positioning of the pagination dots, see the pagination section of Widget interaction design guidance.



For widgets that use containers, the gutter between each element is 4px, and the containers should touch the edges of the margins. Your content should also use spacing and sizing values of Multiples of Four Px to achieve a clean, pixel perfect design across different screen resolutions.

You should also consult the guidance for spacing and gutters in Content design basics for Windows apps when designing your content.

Typography

The quick brown fox jumped over the lazy dog.

The quick brown fox jumped over the lazy dog.

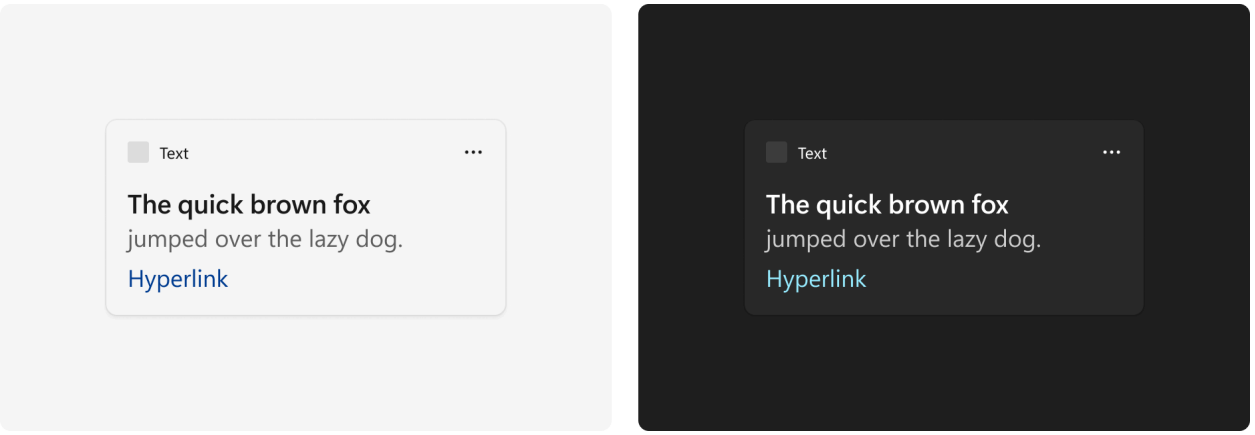
For accessibility, the following table presents the text of the table shown in the image above.

Expand table

Example	Size / Line height	Adaptive cards formula
Caption	12/16 epx	Small, Lighter
Body	14/20 epx	Default, Lighter
Body (for hyperlinks)	14/20 epx	Default, Lighter, Accent
Body Strong	14/20 epx	Default, Bolder
Body Large	18/24 epx	Medium, Lighter
Body Largest	18/24 epx	Medium, Bolder
Subtitle	20/28 epx	Large, Bolder
Title	28/36 epx	Extra Large, Bolder

Segoe UI is the typeface used in Widgets and across Windows. The above type ramp includes the formulations of how to properly set the right styles in the Adaptive Cards Designer. Typeface styling should not deviate from the specified formulas above. For

more information on using the Adaptive Cards Designer to create widget templates, see Create a widget template with the Adaptive Card Designer.



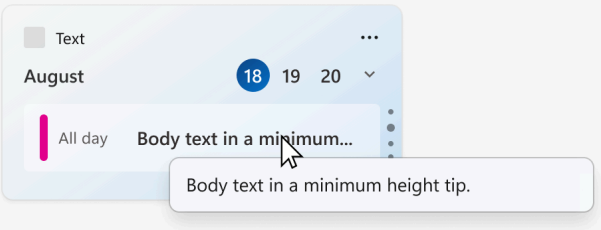
Within the Adaptive Cards Designer, titles and body copy use the default color associated with the widget theme. An additional option to differentiate title from body copy further is to use the subtle version of the default color. The accent color is only used for hyperlinks.

Iconography

Profile pictures

If your widget includes showing user profiles (for example, a social media feed or stream) use one of the following allowed circle profile sizes: 96x96px, 48x48px, 32x32px, or 24x24px.

Tool tips



Tool tips can be used when title text gets truncated in the widget. For best practices, text should fit neatly within the widget space and not need truncation however, that may not always happen depending on scenarios like language localization, system text scaling, or when quoting something (i.e. article title, name of a song). This does not apply to body text on a widget.

Widget states and built-in UI components

Article • 11/10/2022

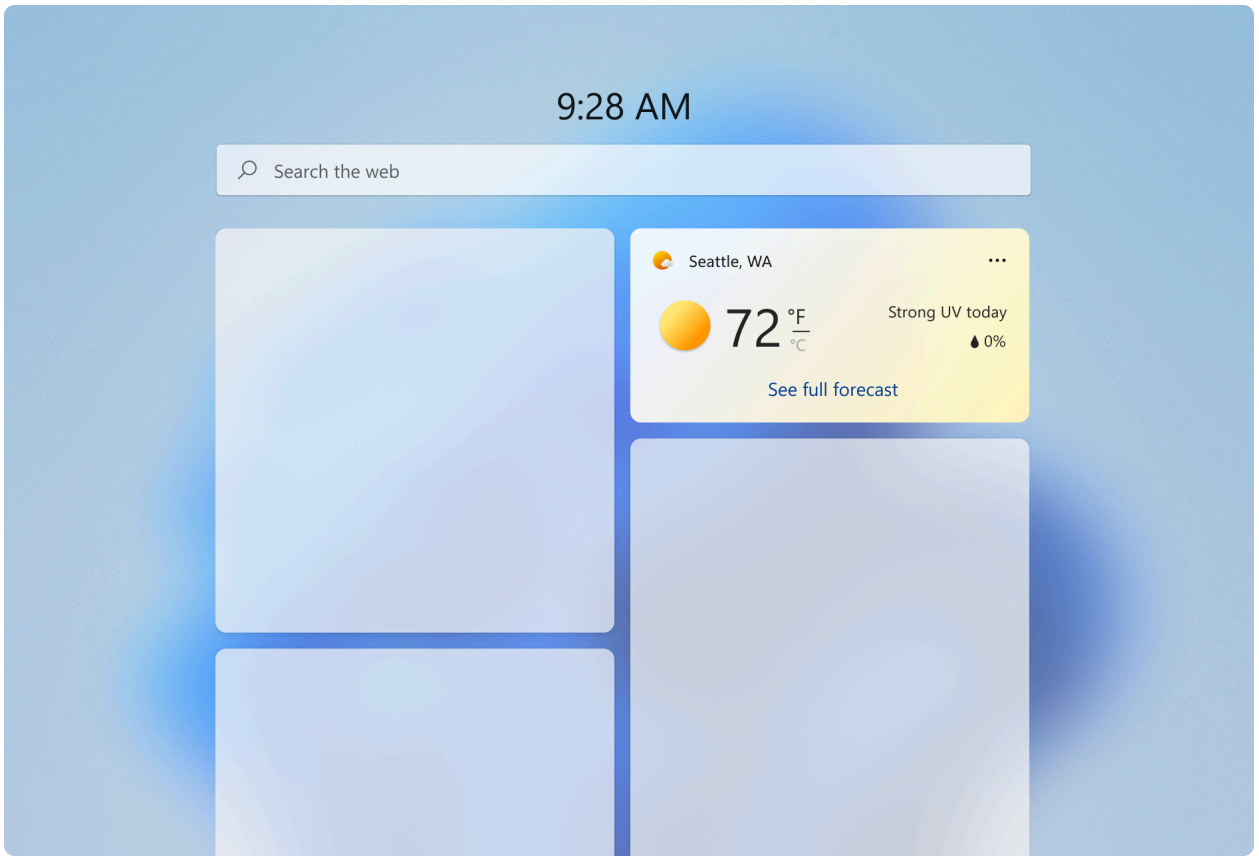
> **Note**
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

> **Important**
>
> The feature described in this topic is available in Dev Channel preview builds of Windows starting with build 25217. For information on preview builds of Windows, see Windows 10 Insider Preview.

Widget states

When a widget is displayed on the Widgets Board, there are several different states that it can be in, depending on the current state of the widgets board and your app, such as when the widget is loading, when the widget is in an error state, or when the user has customized the widgets layout. Some states are designed and implemented by your app while others are built into the Widgets host. This section shows and describes each widget state. Keep in mind that widgets support both light and dark themes, so the built-in states and the states you customize may both look different depending on the current theme.

Default state



The default state is what the widget looks like when it is running normally. This is the primary user experience for your widget. You design the layout for your widget's default state. Although the UI of your widget's default state may change in response to user configuration, your widget's default state should be fully implemented and should not be empty before user configuration. If your widget requires the user to sign-in, you may want to implement a signed-out state, described below. For design guidance for creating the default state for your widget, see Widget design fundamentals.

DO

- When in the default, active state a widget should feel personal and connected to user.
- Widgets should show engaging content that brings the user value in the current moment.
- Give the user the ability to start interacting with widget right away.
- Provide a UI that reflects the UI of your app, while staying within the design constraints for widgets, in order to maximize consistency and to lessen the learning curve.
- Consider using the user's location to pre-populate the data for content like sports and suggested calendars to add instead of generic data.
- Allow ample breathing space between elements.

DON'T

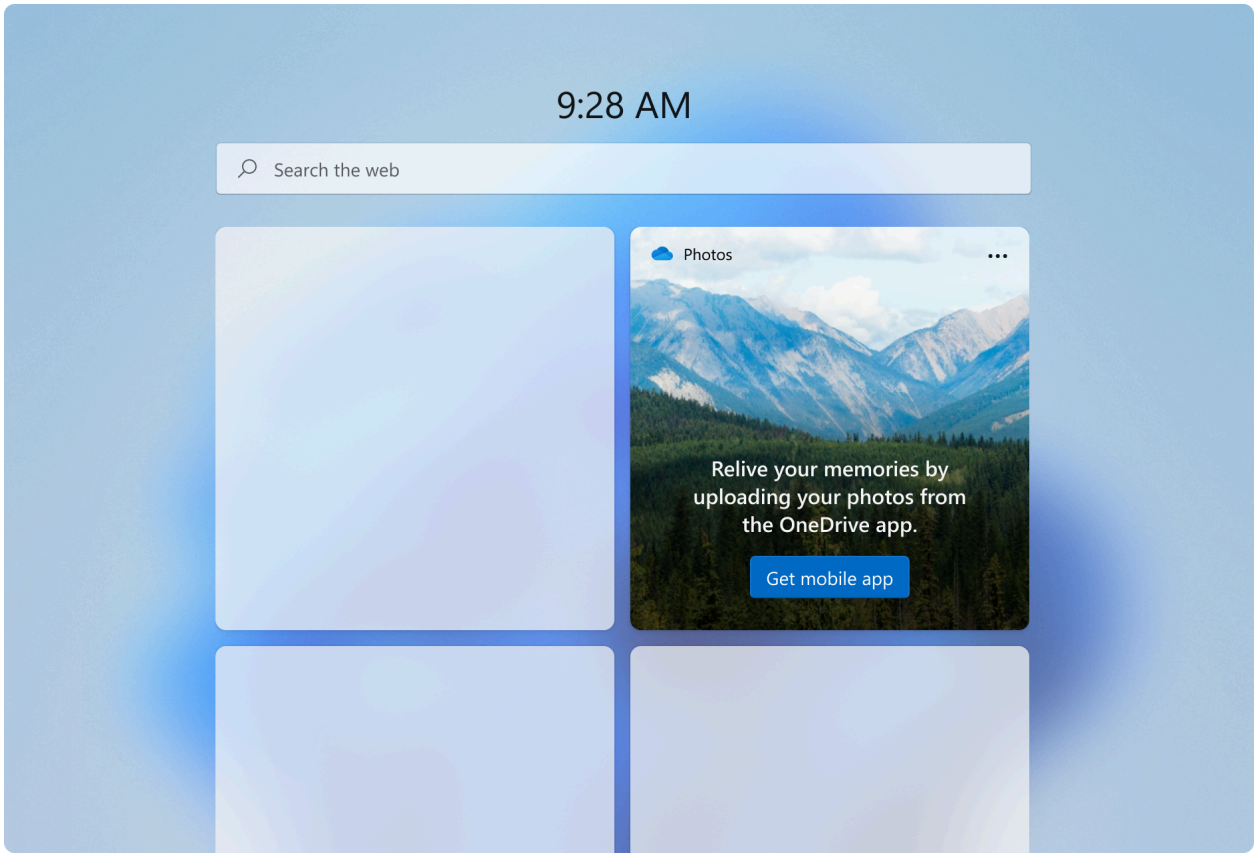
- Use your widget for generic commercial offers. The content should reflect the user's desires and intent.
- Avoid busy, complex layouts.

Aim for comfortable information density and healthy negative space within each widget size to help with the glance and go model. If you have a lot of information to include, consider the next size up to show more content. Also consider how difficult/easy the content will be for a user to glance and consume.

Consider adding moments of surprise + delight to your widgets to elevate the experience. For example, for the Family or Calendar widgets you could highlight a child's birthday via different visual treatments.

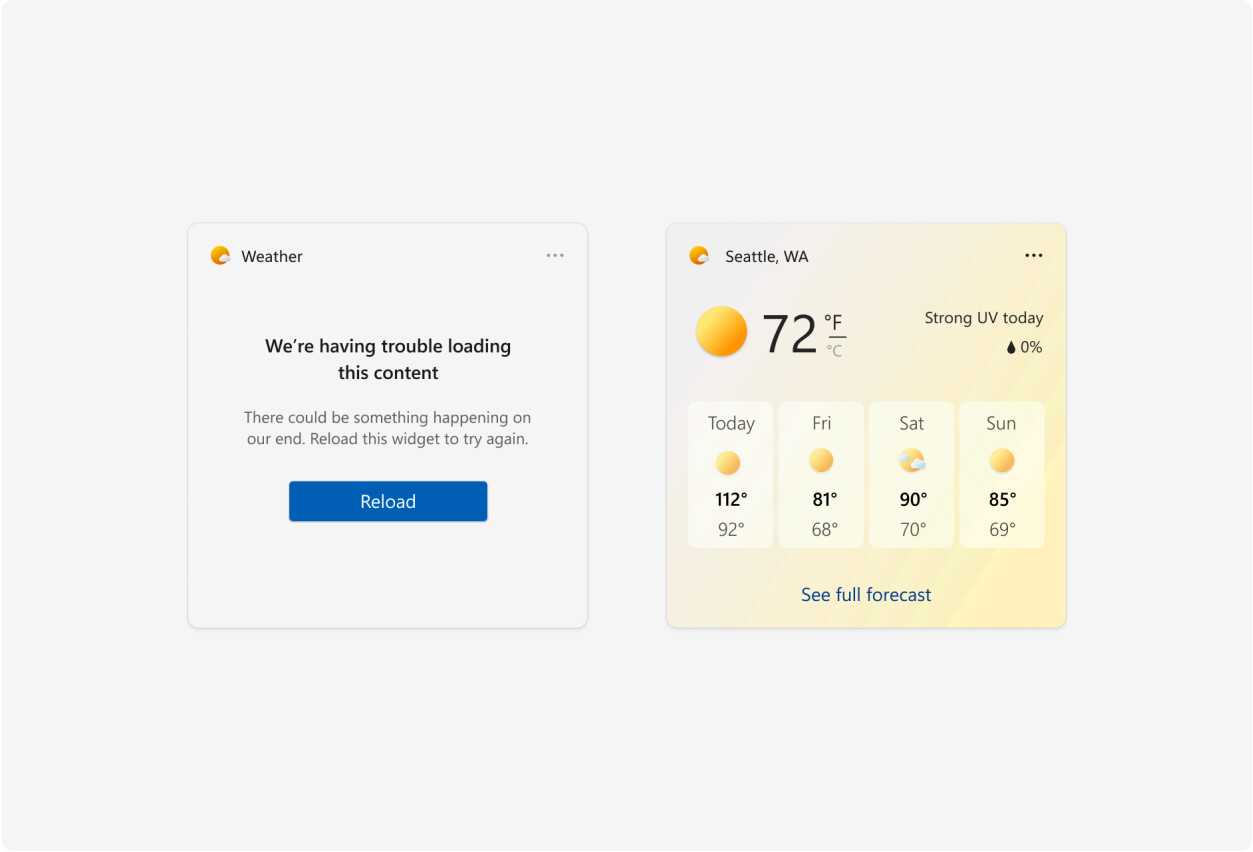
This is the state with the most design flexibility. Use the guidelines in this articles as well as Widget principles, Widget design fundamentals, and Widget interaction design guidance to design how you want to layout your content.

Signed-out state (for widgets that require authentication)



Some widget scenarios may require that the user must sign in or perform other actions to be able to see personalized widget content. When the user is not signed in, you should consider presenting non-personalized content.

Error state - system provided



If for some reason, the Widgets Board can't retrieve the layout or data for a widget, it will display an error state. Windows will show the widget header with an error message and a reload button. This message will look the same for every widget.

If there is cached content available to be displayed, the widget header will show when data was last refreshed in the following format:

1. The number of minutes if less than an hour
2. Rounding to the nearest hour if over an hour

Long widget partner names will get truncated while showing a cached message at 15 characters max.

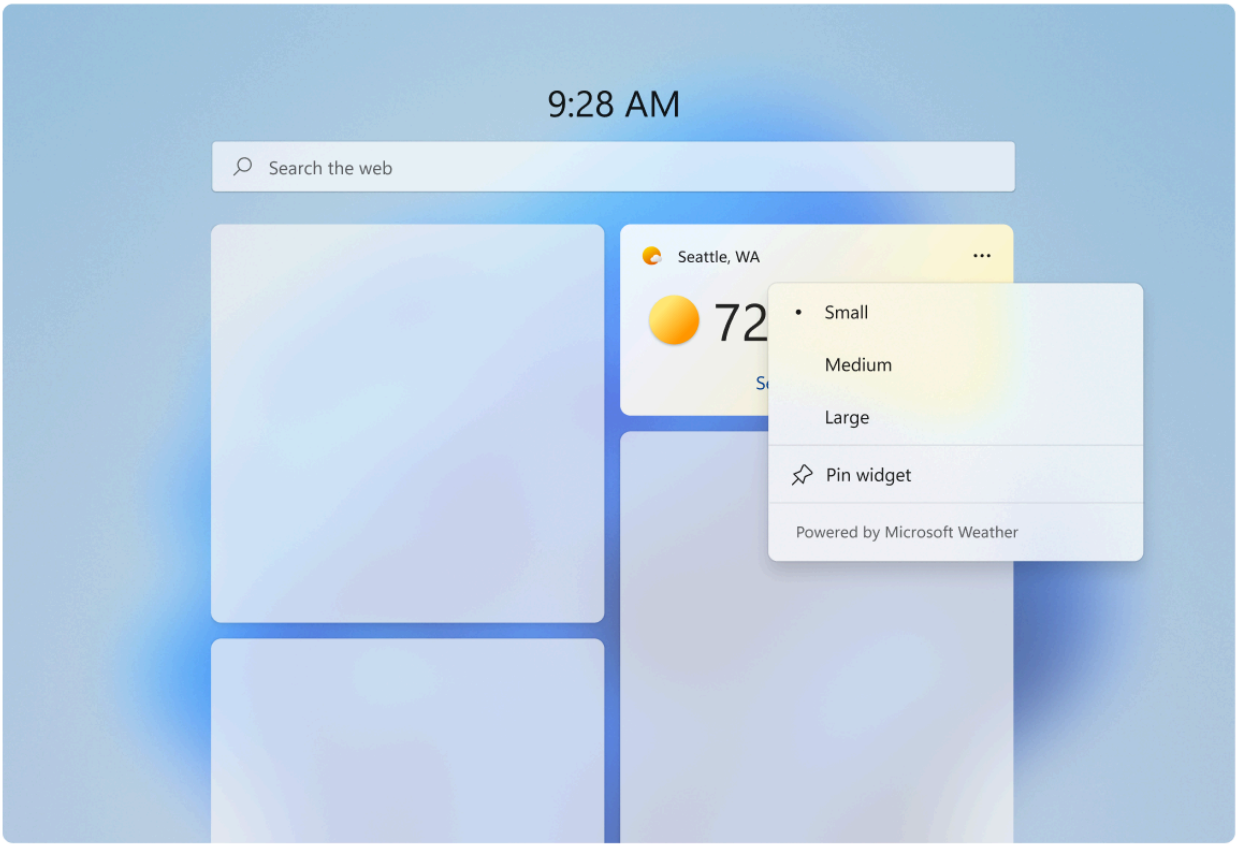
Customization state

Starting with Windows App SDK 1.4, widgets can provide a customization template that provides controls for the user to customize the widget's appearance or the data displayed by the widget. The customization UI is defined in a JSON template.

Built-in widget UI components

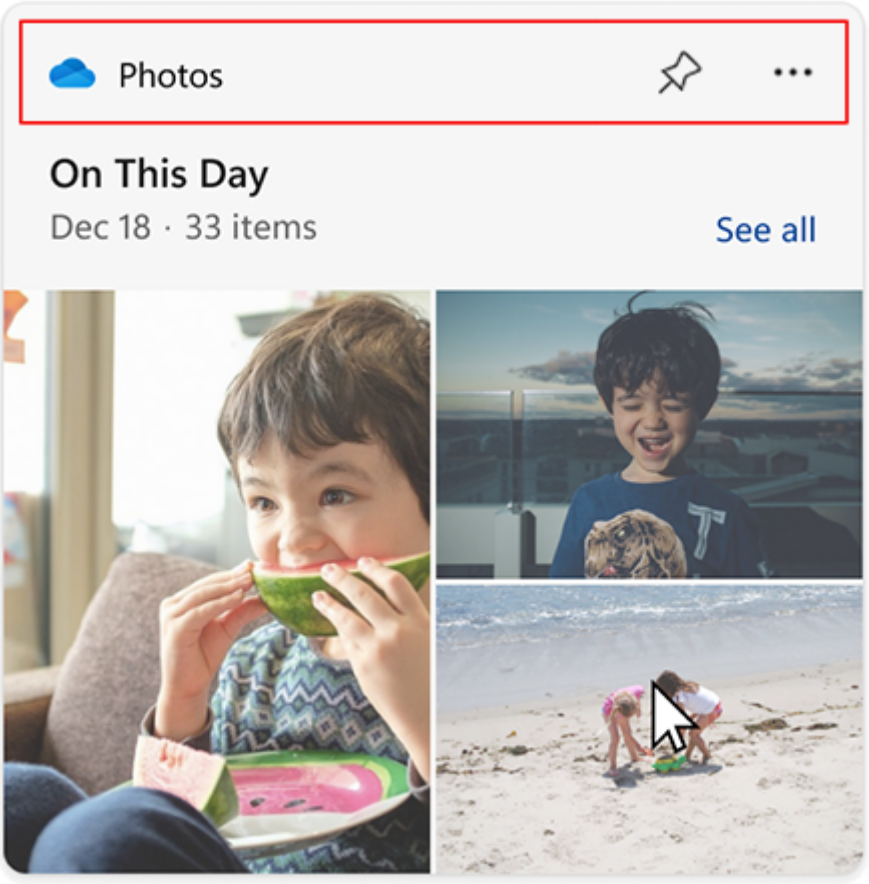
Some UI elements of a widget are built into the widgets experience and, while these elements are not customizable by widget providers, it's important to be aware of what these elements are and how they behave.

Context menu (system provided)



The context menu is displayed when the user clicks on the three-dot icon on the top right. This menu allows users to select their preferred widget size and access the widget's configuration state. Partners will use the same template widget register “powered by ___”.

Attribution area



The attribution area is rendered by the widgets board based on the widget name and icon provided during widget registration. For more information on registering widgets, see Widget provider package manifest XML format.

Widget interaction design guidance

Article • 11/10/2022

> **Note**
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

> **Important**
>
> The feature described in this topic is available in Dev Channel preview builds of Windows starting with build 25217. For information on preview builds of Windows, see Windows 10 Insider Preview.

This article provides detailed guidance for designing interaction for Windows widgets.

Navigation

A widget should be glanceable and focused, and should represent a single aspect of the app's primary purpose. Widgets may provide one or more calls to action. When the user clicks on a call to action, the widget should launch the associated app or website instead of implementing the action in the widget itself. A widget has only one primary page that can house multiple interactions. Clicking on an item in the widget should never take you to a completely different view of the widget. For example, in a weather widget you might show the weather for multiple days but clicking on one of the days will not expand details inline, but will instead launch the app or web.

The following are the maximum number of touch points recommended for each supported widget size.

Expand table

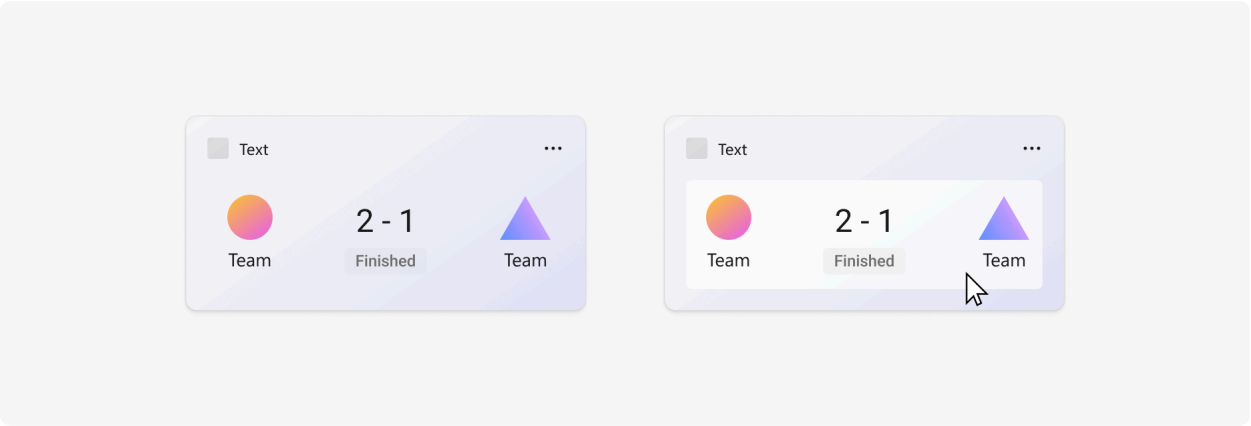
Widget size	Maximum touchpoints
small	1
medium	3
large	4

The following navigation elements are not supported in Windows Widgets:

- Pivots will not be supported within widgets
- L2 Pages will not be supported within widgets
- Vertical or horizontal scrolling will not be supported within Widgets

Containers

The following images show example uses of container elements in a widget template. The containers group visual elements into columns and rows to create a hierarchical grid structure.



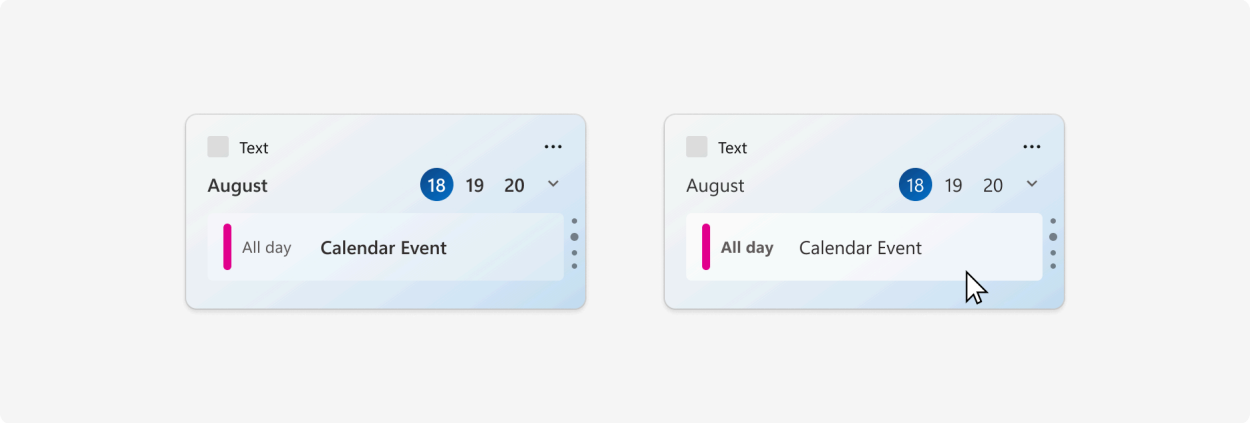


Image links

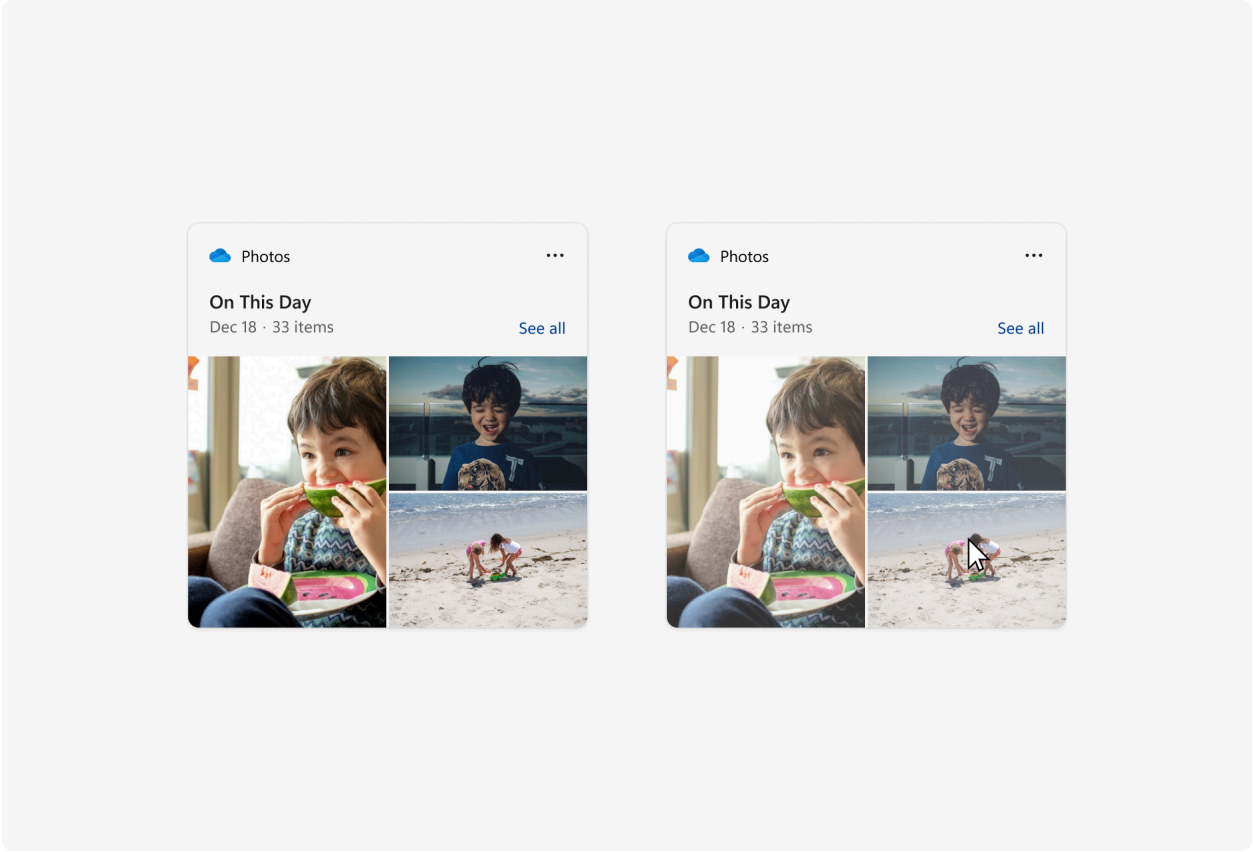
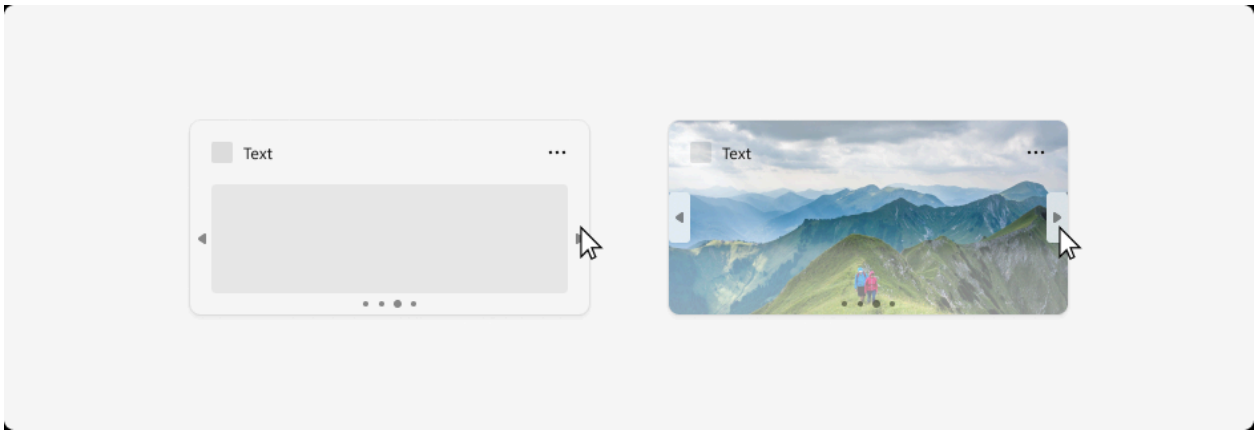
The following images show example uses of image link elements in a widget template.



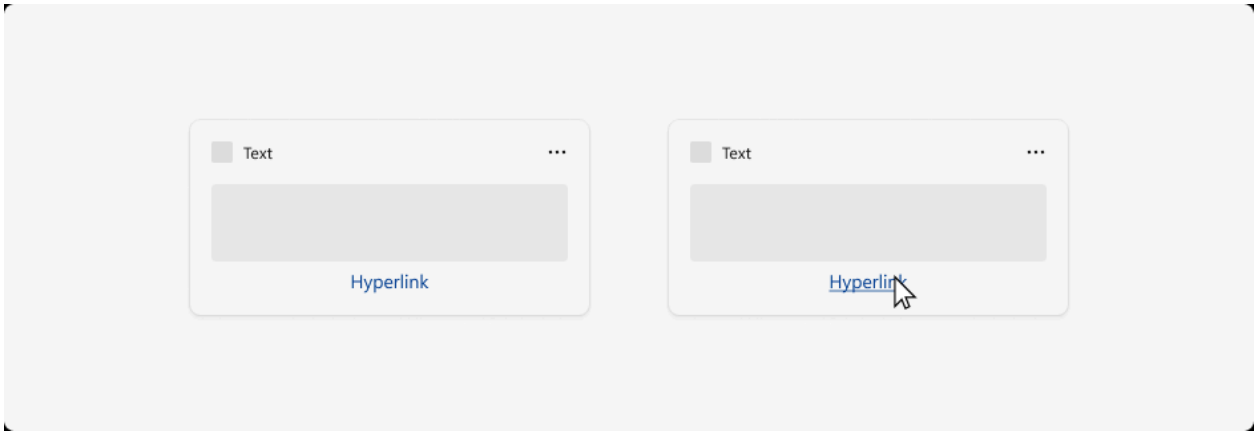
Pagination

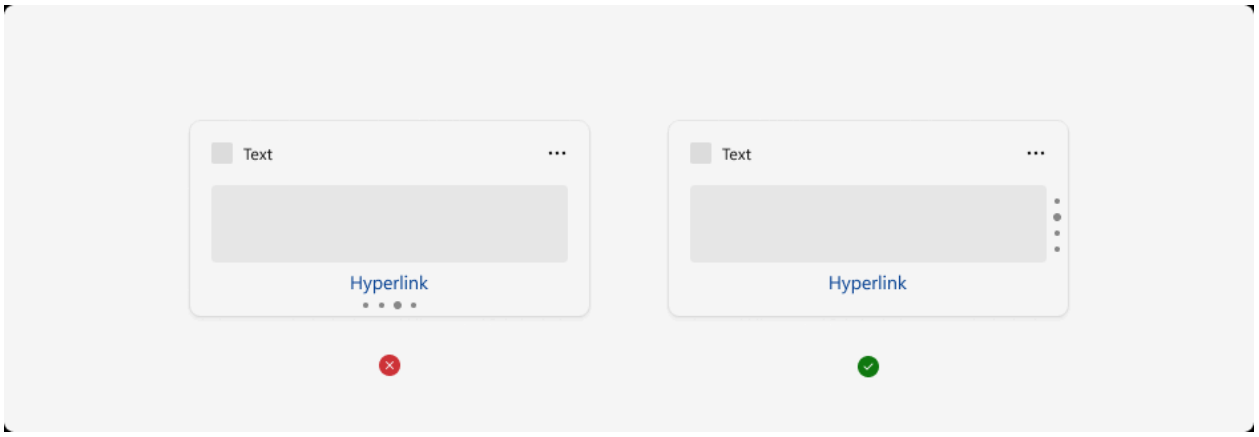
The following images show examples of pagination in a widget template. The pagination controls can be aligned horizontally or vertically. Navigation arrows appear in response to a cursor hover.



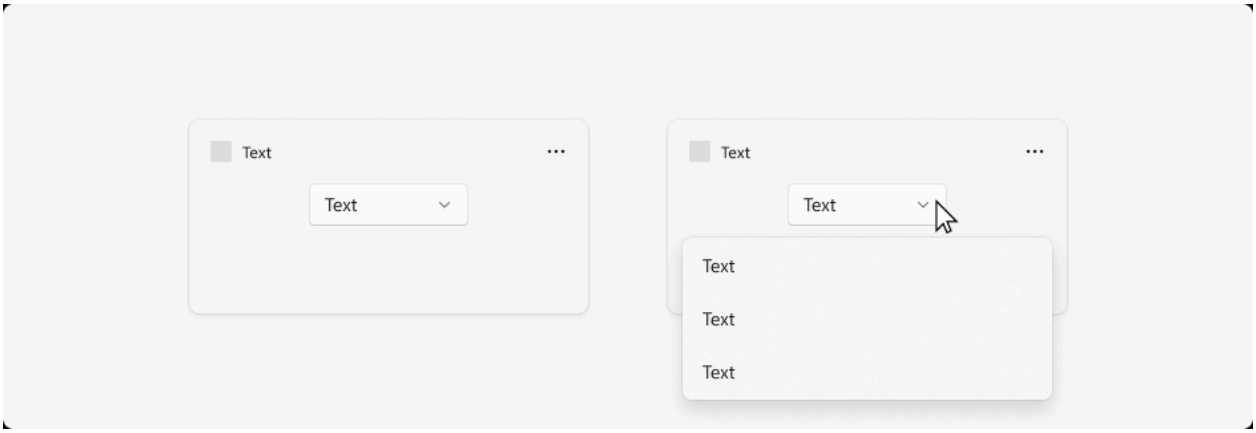
Hyperlinks

The following images show example of hyperlinks in a widget template.





Dropdown menus



Widgets are able to extend slightly beyond their widget size temporarily if the user is interacting with a menu or dropdown. The menu behavior should be light dismiss and close the menu if a user click outside of the menu / dropdown area.

Create a widget template with the Adaptive Cards Designer

Article • 01/24/2025

> **Note**
>
> **Some information relates to pre-released product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.**

> **Important**
>
> The feature described in this topic is available in Dev Channel preview builds of Windows starting with build 25217. For information on preview builds of Windows, see Windows 10 Insider Preview.

The UI and interaction for Windows Widgets are implemented using Adaptive Cards. Each widget provides a visual template and, optionally, a data template which are defined using JSON documents that conform to the Adaptive Cards schema. This article walks you through the steps to create a simple widget template.

A counting widget

The example in this article is a simple counting widget that displays an integer value and allows the user to increment the value by clicking on a button in the widget's UI. This example template uses data binding to automatically update the UI based on the data context.

Apps need to implement a widget provider to generate and update the widget template and/or data and pass them to the widget host. The article Implement a widget provider in a win32 app provides step-by-step guidance for implementing the widget provider for the counting widget that we will generate in the steps below.

The Adaptive Cards Designer

The Adaptive Cards Designer is an online interactive tool that makes it easy to generate JSON templates for Adaptive Cards. Using the designer, you can see the

rendered visuals and the data binding behavior in real-time as you build your widget template. Follow the link to open the designer, which will be used for all of the steps in this walkthrough.

Create an empty template from a preset

At the top of the page, from the **Select host app** dropdown, choose Widgets Board. This will set the container size for the Adaptive Card to have a size that is supported for widgets. Note that widgets support small, medium, and large sizes. The size of the default template preset is the correct size for a small widget. Don't worry if the content overflows the borders because we will be replacing it with content designed to fit inside the widget.

There are three text editors at the bottom of the page. The one labeled **Card Payload Editor** contains the JSON definition of your widget's UI. The editor labeled **Sample Data Editor** contains JSON that defines an optional data context for your widget. The data context is bound dynamically to the Adaptive Card when the widget is rendered. For more information about data binding in Adaptive Cards, see Adaptive Cards Template Language.

The third text editor is labeled **Sample Host Data Editor**. Note that this editor may collapse below the page's other two editors. If so, click the + to expand the editor. Widget host apps can specify host properties that you can use in your widget template to dynamically display different content based on the current property values. The Widgets Board supports the following host properties.

Expand table

Property	Value	Description
host.widgetSize	"small", "medium", or "large"	The size of the pinned widget.
host.hostTheme	"light" or "dark"	The current theme of the device on which the Widgets Board is displayed.
host.isSettingsPayload	true or false	When this value is true, the user has clicked on the **Customize widget** button in the widget context menu. You can use this property value to display customization settings UI elements. This is an alternative method to using IWidgetProvider2.OnCustomizationRequested to alter the JSON payload in the widget provider

Property	Value	Description
		app. For more information, see Implementing widget customization.
host.isHeaderSupported	true or false	When this value is true, header customization is supported. For more information, see isHeaderSupported.
host.isHeader	true or false	When this value is true, the host is requesting a payload specifically for rendering of the widget header.
host.isWebSupported	true or false	When this value is false, the host does not currently support loading a widget's web content. When this occurs, web widgets will display the fallback JSON payload supplied by the widget provider, but this value can be use to further customize the content. For more information, see Web widget providers
host.isUserContextAuthenticated	true or false	When this value is false, the only action that is supported is Action.OpenUrl. The value of *isUserContextAuthenticated* can be used to adjust widget content appropriately, given the interactivity limitations.

The **Container size** and **Theme** dropdowns next to the **Select host app** dropdown at the top of the page allow you to set these properties without manually editing the sample host JSON in the editor.

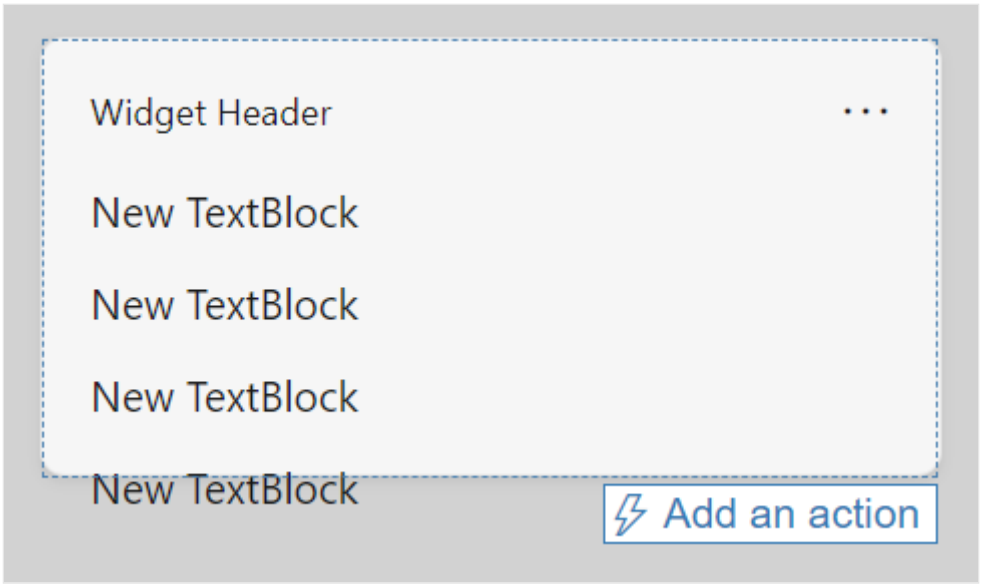
Create a new card

In the upper left corner of the page, click **New card**. In the *Create* dialog, select **Blank Card**. You should now see an empty Adaptive Card. You will also notice that the JSON document in the sample data editor is empty.

The counting widget that we will create is very simple, only consisting of 4 TextBlock elements and one action of type Action.Execute, that defines the widget's button.

Add TextBlock elements

Add four **TextBlock** elements by dragging them from the **Card elements** pane on the left of the page onto the blank adaptive card in the preview pane. At this point, the widget preview should look like the following image. The content again overflows outside of the widget borders, but this will be fixed in the following steps.



Implementing conditional layout

The **Card Payload Editor** has been updated to reflect the **TextBlock** elements that we added. Replace the JSON string for the **body** object with the following:

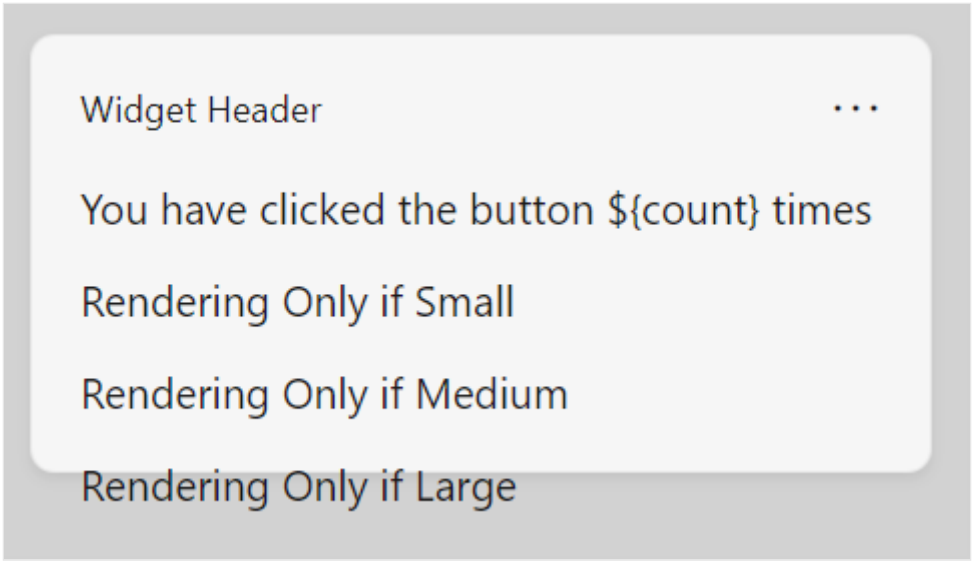
JSON

```
"body": [
    {
        "type": "TextBlock",
        "text": "You have clicked the button ${count} times"
    },
    {
        "type": "TextBlock",
        "text": "Rendering only if medium",
        "$when": "${$host.widgetSize==\"medium\"}"
    },
    {
        "type": "TextBlock",
        "text": "Rendering only if small",
        "$when": "${$host.widgetSize==\"small\"}"
    },
    {
        "type": "TextBlock",
        "text": "Rendering only if large",
        "$when": "${$host.widgetSize==\"large\"}"
    }
]
```

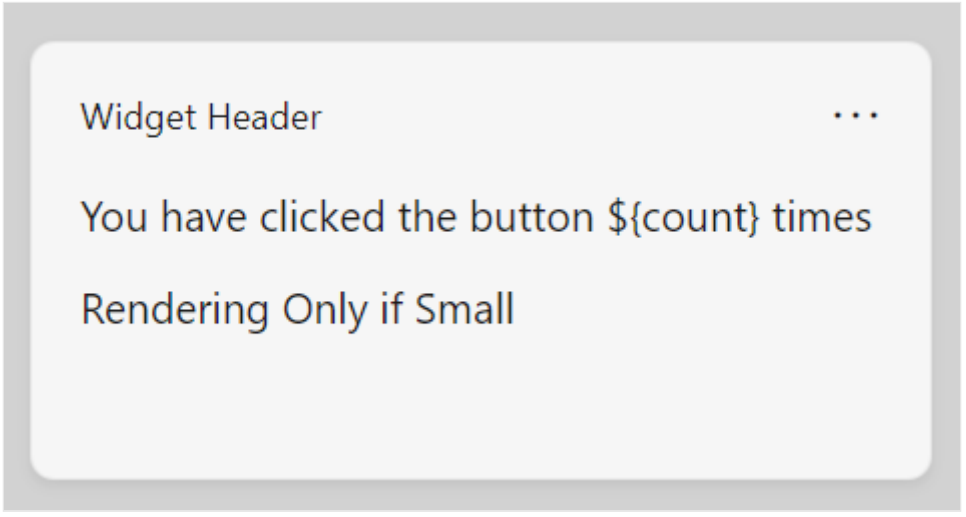
In the Adaptive Cards Template Language, the `$when` property specifies that the containing element is displayed when the associated value evaluates to true. If the value evaluates to false, the containing element is not displayed. In the **body** element in our example, one of the three **TextBlock** elements will be shown, and the other two hidden,

depending on the value of the `$host.widgetSize` property. For more information about the conditionals supported in Adaptive Cards, see Conditional layout with $when.

Now the preview should look like the following image:



Note that the conditional statements aren't being reflected in the preview. This is because the designer isn't simulating the behavior of the widget host. Click the **Preview mode** button at the top of the page to start the simulation. The widget preview now looks like the following image:



From the **Container size** dropdown, select "Medium" and note that the preview switches to only show the **TextBlock** for the medium size. The container in the preview also changes size, demonstrating how you can use the preview to make sure that your UI fits within the widget container for each supported size.

Bind to the data context

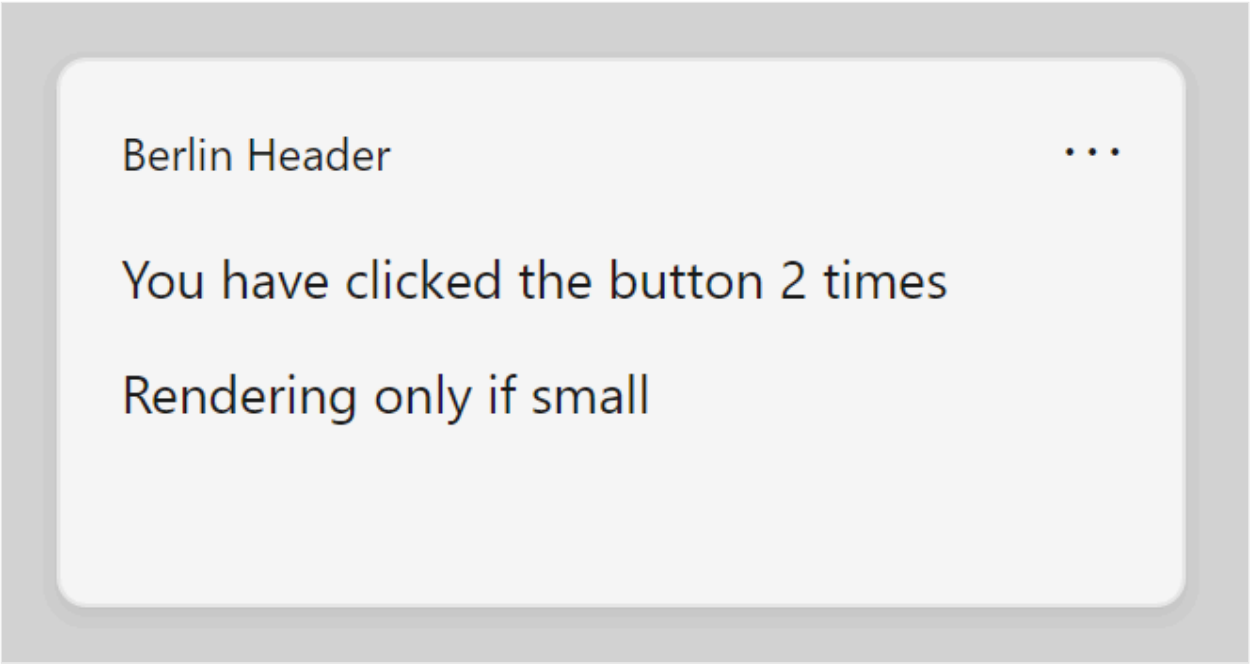
Our example widget will use a custom state property named "count". You can see in the current template that the value for the first **TextBlock** includes the variable reference

`$count`. When the widget is running in the Widgets Board, the widget provider is responsible for assembling the data payload and passing it to the widget host. At design time, you can use the **Sample Data Editor** to prototype your data payload and see how different values impact the display of your widget. Replace the empty data payload with the following JSON.

JSON

```
{"count": "2"}
```

Note that the preview now inserts the value specified for the *count* property into the text for the first **TextBlock**.



Add a button

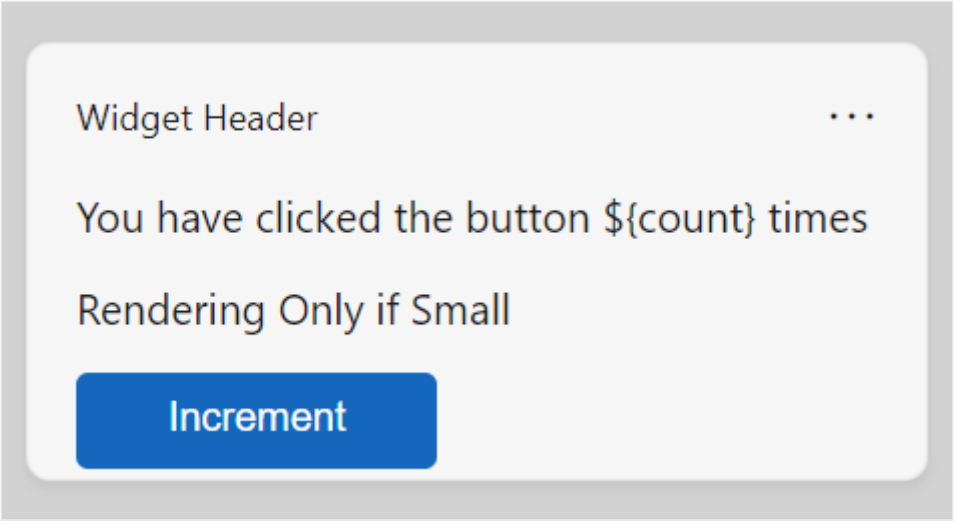
The next step is to add a button to our widget. In the widget host, when the user clicks the button, the host will make a request to the widget provider. For this example, the widget provider will increment the count value and return an updated data payload. Because this operation requires a widget provider, you won't be able to view this behavior in the Adaptive Cards Designer, but you can still use the designer to adjust the layout of your button within your UI.

With Adaptive Cards, interactive elements are defined with **action** elements. Add the following block of JSON directly after the **body** element in the card payload editor. Be sure to add a comma after the closing bracket (]) of the body element or the designer will report a formatting error.

JSON

```
,
"actions": [
    {
        "type": "Action.Execute",
        "title": "Increment",
        "verb": "inc"
    }
]
```

In this JSON string, *type* property specifies the type of action that is being represented. Widgets only support the "Action.Execute" action type. The *title* contains the text that is displayed on the button for the action. The *verb* property is an app-defined string that the widget host will send to the widget provider to communicate the intent associated with the action. A widget can have multiple actions, and the widget provider code will check the value of the verb in the request to determine what action to take.



The complete widget template

The following code listing shows the final version of the JSON payload.

JSON

```
{
    "type": "AdaptiveCard",
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.6",
    "body": [
    {
      "type": "TextBlock",
      "text": "You have clicked the button ${count} times"
    },
    {
```

```
      "type": "TextBlock",
       "text": "Rendering Only if Small",
      "$when": "${$host.widgetSize==\"small\"}"
    },
    {
      "type": "TextBlock",
      "text": "Rendering Only if Medium",
      "$when": "${$host.widgetSize==\"medium\"}"
    },
    {
      "type": "TextBlock",
      "text": "Rendering Only if Large",
      "$when": "${$host.widgetSize==\"large\"}"
    }
    ],
   "actions": [
    {
      "type": "Action.Execute",
      "title": "Increment",
      "verb": "inc"
    }
  ]
}
```

Settings payload example

The following code listing shows a simple example of a JSON payload that uses the **host.isSettingsPayload** property to display different content when the user has clicked the **Customize widget** button.

JSON

```
{
    "type": "AdaptiveCard",
    "body": [
    {
        "type": "Container",
        "items":[
            {
                "type": "TextBlock",
                "text": "Content payload",
                "$when": "${!$host.isSettingsPayload}"
            }
        ]
    },
    {
        "type": "Container",
        "items":[
            {
                "type": "TextBlock",
                "text": "Settings payload",
```

```
                "$when": "${$host.isSettingsPayload}"
            }
        ]
    }
],
"actions": [
    {
    "type": "Action.Submit",
    "title": "Increment",
    "verb": "inc",
    "$when": "${!$host.isSettingsPayload}"
    },
    {
    "type": "Action.Submit",
    "title": "Update Setting",
    "verb": "setting",
    "$when": "${$host.isSettingsPayload}"
    }
],
    "$schema": "http://adaptivecards.io/schemas/adaptive-card.json",
    "version": "1.6"
}
```

Integrate with the widget picker

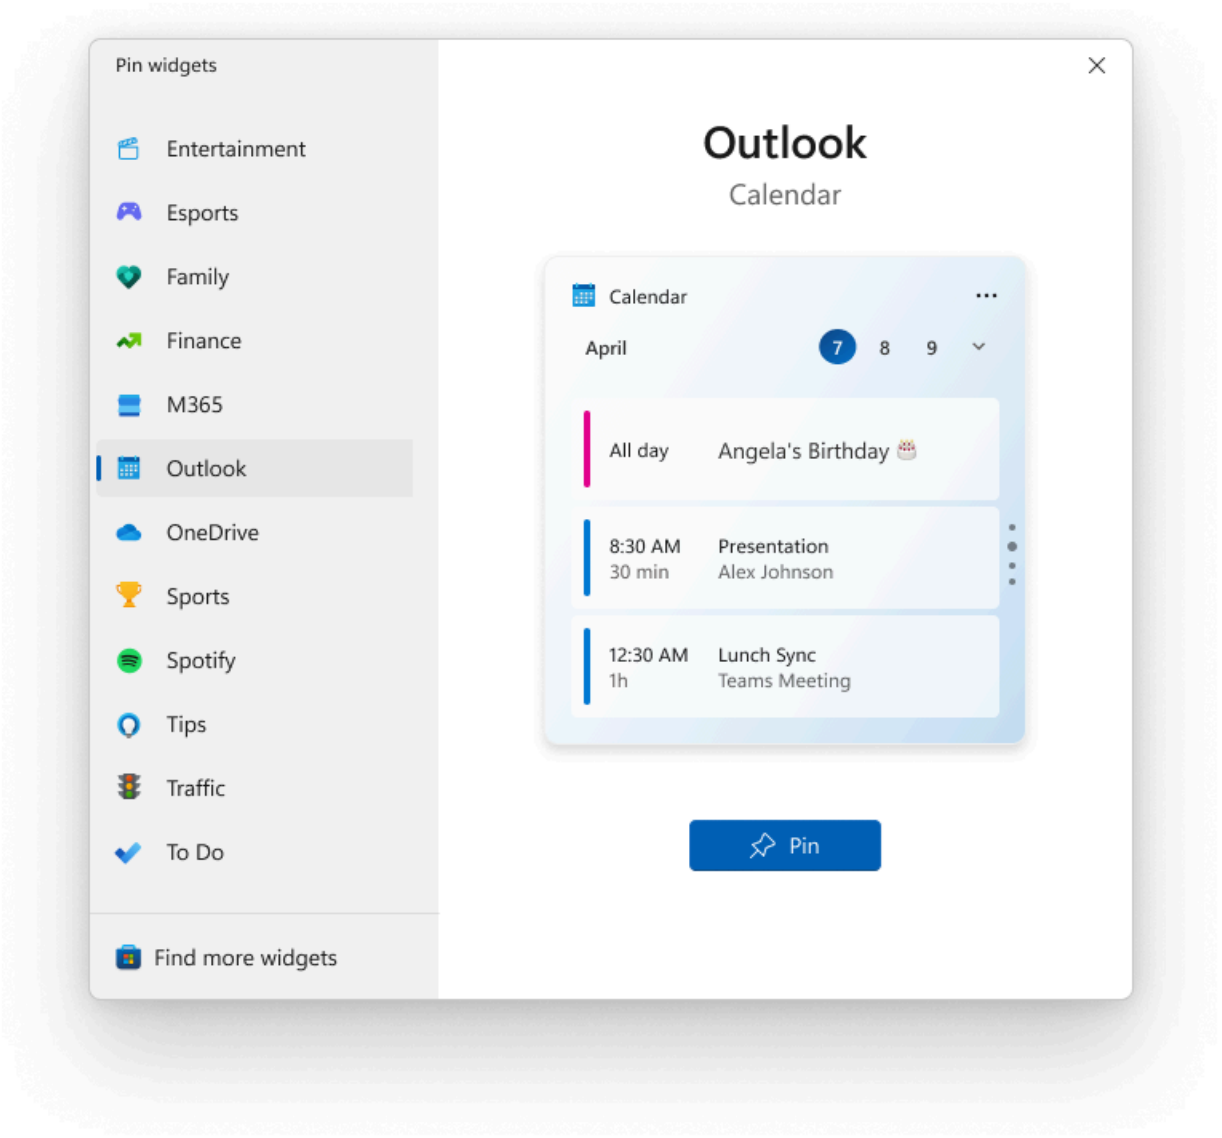
Article • 02/02/2023

In the current release, the only Widgets host is the Widgets Board built into Windows 11. The Widgets Board displays widgets and manages their layout on the board. It also provides a widget picker that allows the user to select which available widgets are visible on the board. This article describes the assets required for a widget to successfully integrate into the widget picker.

Widget screenshot image

Each widget must provide a screenshot image that is displayed as a preview in the widget picker when the widget has focus. The screenshot is specified by the widget provider in the package manifest for the app. For technical information on how to specify an image file to use for the widget screenshot, see Implement a widget provider in a win32 app and Widget provider package manifest XML format.

The following screenshot illustrates the placement of the screenshot image within the widget picker.



Screenshot image requirements

In order to provide a consistent user experience, widget screenshots for the widget picker must follow the following guidelines.

- The screenshot should display the medium size version of your widget.
- The image should be 300 pixels wide and 304 pixels tall.
- The image should have transparent, rounded corners.

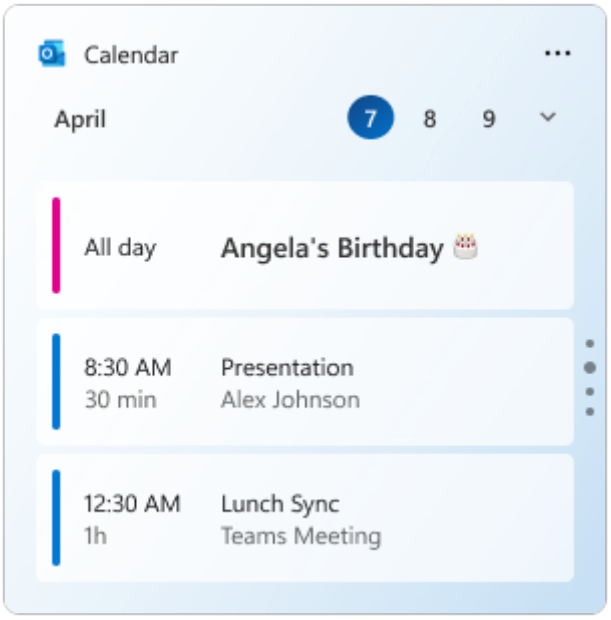
The widget provider manifest includes three different **Screenshot** elements that you can set. The top-level screenshot is required and will be used as the default by the widget picker. The **LightMode** and **DarkMode** sections of the manifest are optional and allow you to specify separate screenshots for your widget in light and dark modes. If you supply one or both of these optional screenshots, the widget picker will use the one that matches the device's current theme. If you do not supply an image specifically for the current theme, the widget picker will use the default, top-level screenshot instead.

You may provide widget screenshots for multiple locales. The locale for each screenshot is specified with the path to the asset relative to your app package.

- Create a directory in your packaging project for the image assets. For example: "Assets".
- The language-neutral or fallback assets can be placed directly in this folder. For example: "Assets/Screenshot.png"
- Language-specific assets can be placed in subdirectories named after the locale to which they apply. For example:
  - "English (United States)" assets should be placed in a subdirectory named "en-us": "Assets/en-us/Screenshot.png"
  - "French (France)" assets should be placed in a subdirectory named "fr-fr": "Assets/fr-fr/Screenshot.png"
- Reference these images in the appxmanifest using the ms-appx: URI scheme. For example: Screenshot="ms-appx:Assets\Screenshot.png"
- If you don't include an image for a specific locale, then the fallback image in the root directory will be used.

The resource loader will automatically choose the language-appropriate asset to display. For more information, see: Load images and assets tailored for scale, theme, high contrast, and others.

The following is an example of a widget screenshot image.



Design resources for Windows apps

Article • 01/07/2025

This topic provides a variety of design and UI-related resources for creating visually appealing and user-friendly Windows applications.

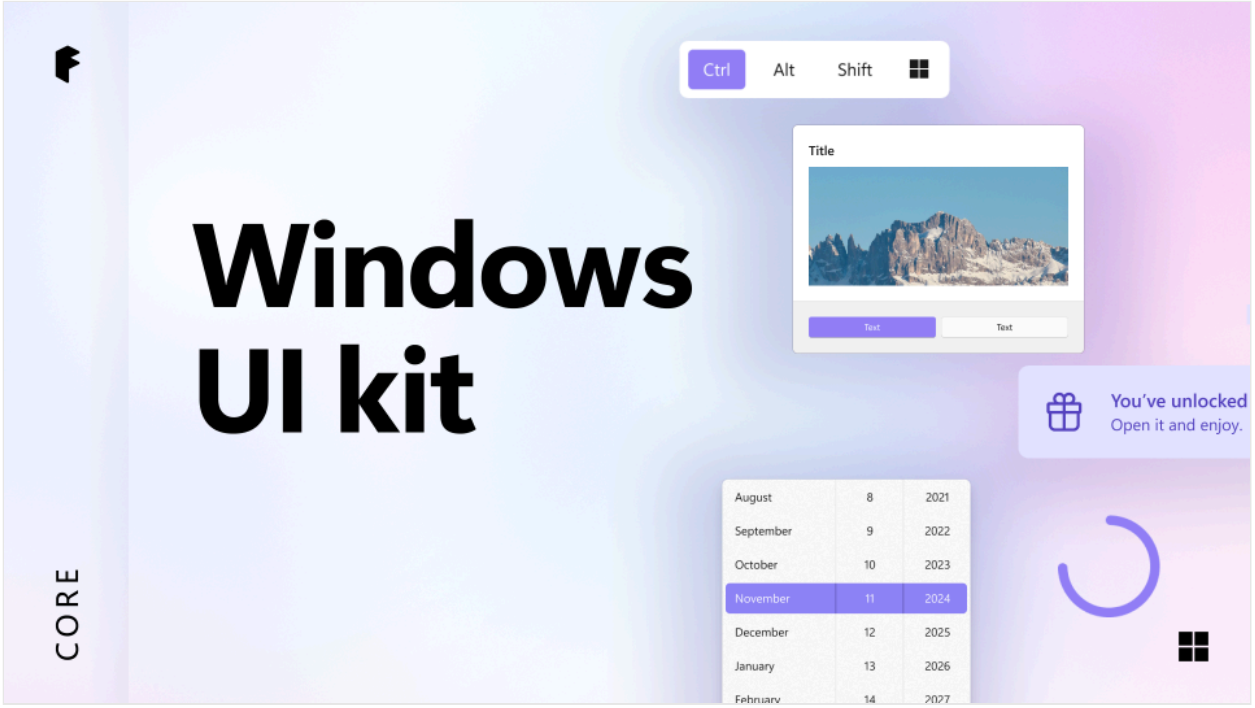
Fonts

The Windows type system helps you create structure and hierarchy in your content in order to maximize legibility and readability in your UI (for more details, see Segoe UI font family).

The following fonts are recommended:

- Segoe UI Variable (see Typography in Windows)
- Segoe Fluent Icons (see Segoe Fluent Icons font)
- Segoe MDL2 (see Segoe MDL2 Assets icons)

Windows UI Kit



The Windows Design Kit for Figma provides a comprehensive toolkit to help developers and designers create visually consistent and engaging Windows apps

The Windows Design Kit is a Figma library that includes:

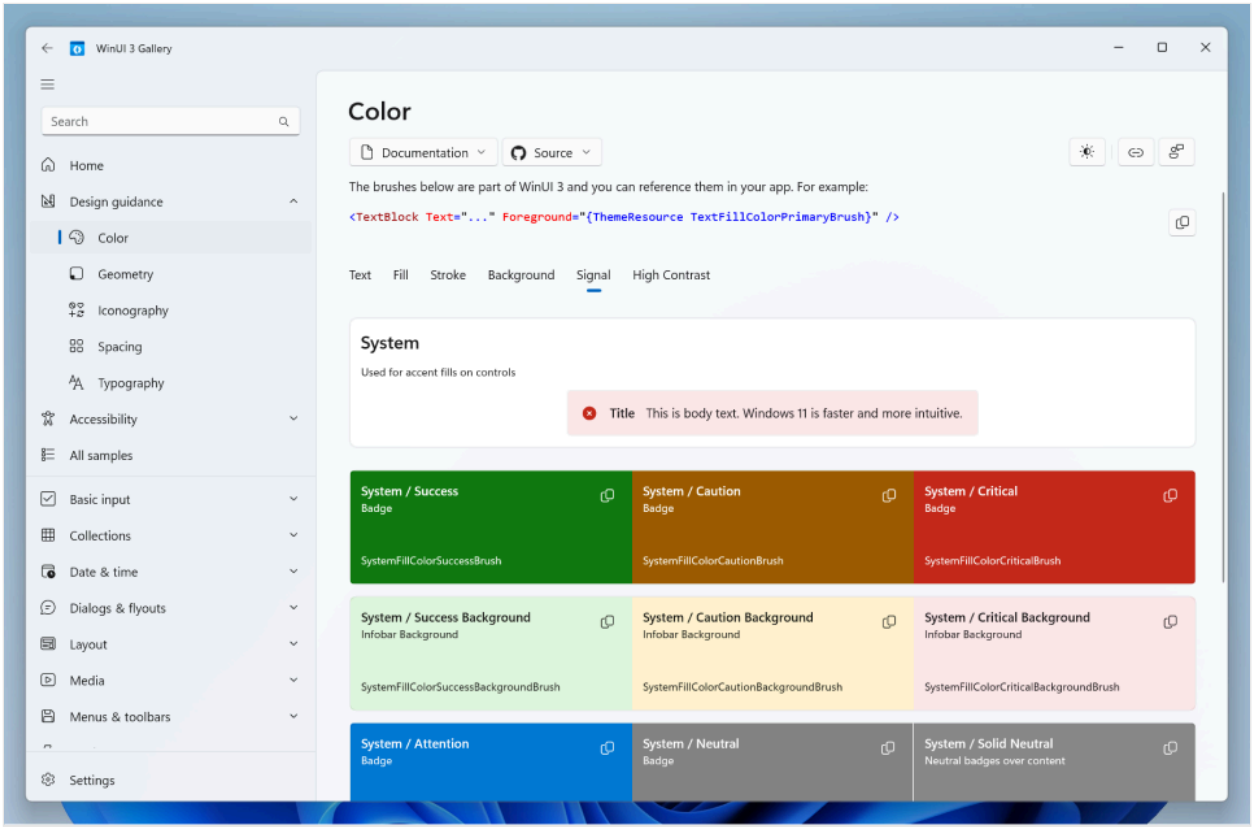
- **UI components**: Prebuilt elements like buttons, toggles, sliders, and more.

- **Design patterns**: Templates for navigation, dialogs, and layouts.
- **Styles and tokens**: Predefined colors, typography, and spacing.

Windows UI Kit for Figma

WinUI Gallery

The Design Guidance section of the WinUI Gallery offers best practices and tools to help you choose and apply the right colors, typography, and icons for your app. The Accessibility section includes code snippets and tips to make your app more inclusive and accessible to all users.



Design Guidance in WinUI Gallery

Samples

Check out the Samples and resources page for complete list of all our Windows app samples.

Develop Windows desktop apps

Article • 02/13/2025

This section of the documentation provides information about APIs and features you can use while developing Windows desktop apps. Some of these features are available by using APIs in the Windows App SDK. Other features are available by using APIs in the Windows OS (via the Windows SDK) and .NET, and don't require use of the Windows App SDK.

> **Important**
>
> If you're working on a UWP app, then refer to Migrate from UWP to the Windows App SDK.

Windows App SDK features

The following table highlights the development features that are provided by the current releases of the Windows App SDK. For more details about the release channels of the Windows App SDK that include each of these features, see Features available by release channel.

Learn about the Windows App SDK

Expand table

Feature	Description
WinUI 3	The premiere native user interface (UI) framework for Windows desktop apps, including managed apps that use C# and .NET and native apps that use C++ with the Win32 API. WinUI 3 provides consistent, intuitive, and accessible experiences using the latest user interface (UI) patterns.
Render text with DWriteCore	Render text using a device-independent text layout system, high quality sub-pixel Microsoft ClearType text rendering, hardware-accelerated text, multi-format text, wide language support, and much more.
Manage resources with MRT Core	Manage app resources such as strings and images in multiple languages, scales, and contrast variants independently of your app's logic.
App lifecycle: App instancing	Control whether multiple instances of your app's process can run at the same time.

Feature	Description
App lifecycle: Rich activation	Process information about different kinds activations for your app.
App lifecycle: Power management	Gain visibility into how your app affects the device's power state, and enable the app to make intelligent decisions about resource usage.
Manage app windows	Create and manage the windows associated with your app.
Push notifications	Send raw notifications and app notifications to your app from the cloud using Azure App Registration identities.
App notifications	Deliver messages to your user with app notifications.
Deployment	Deploy the Windows App SDK runtime with your unpackaged and packaged app

Windows app development features organized by scenario

The following articles provide information to help you get started using features of the full Windows app development platform for common app scenarios, including features provided by the Windows App SDK, the Windows SDK, and the .NET SDK.

- Modernize your existing desktop apps
- User interface and input
- App lifecycle and system services
- Launching Windows apps and managing background tasks
- Communication
- Accessibility
- Audio, video, and camera
- Graphics
- Data and files
- Windows AI and machine learning
- Integrate with Windows
- Devices and sensors
- Security and identity
- Deployment overview

For information about setting up your development environment and getting started creating a new app, see:

Accessibility in Windows 11 and Windows 10

Article • 11/28/2023

Build accessibility into your applications to empower people of all abilities

Products and services—including electronic media—are accessible when they are designed to provide full and successful experiences for as many people as possible.

Build accessible and inclusive Windows applications, with improved functionality and usability, for people with disabilities (both temporary and permanent), personal preferences, specific work styles, or situational constraints (such as shared work spaces, driving, cooking, glare, and so on). Some common solutions include providing information in alternative formats (such as captions on a video) or enabling the use of assistive technologies (such as screen readers).

Everyone should have access to the same rooms in a building, whether they need to use the stairs or the elevator.

This page provides information on how the various Windows development frameworks provide accessibility support for developers building Windows applications, assistive technology developers building tools such as screen readers and magnifiers, and software test engineers creating automated scripts for testing applications.

App lifecycle, background tasks, and system services

Article • 03/19/2025

This article provides an index of development features that are related to scenarios involving managing the lifecycle of Windows apps and using system-level services provided by the Windows OS.

Windows App SDK features

The Windows App SDK provides the following features related to app lifecycle and system services for Windows 10 and later OS releases.

> **Important**
>
> If you're working on a UWP app, then refer to Migrate from UWP to the Windows App SDK.

Expand table

Feature	Description
App lifecycle	Get an overview of managing the lifecycle of your app.
App instancing	Control whether multiple instances of your app's process can run at the same time.
Background tasks	Background tasks are app components that run in the background without a user interface. They can perform actions such as downloading files, syncing data, sending notifications, or updating tiles.
Rich activation	Receive information about different kinds activations for your app.
Power management	Get visibility into how your app affects the device's power state, and enable your app to make intelligent decisions about resource usage.
Restart	Programmatically restart your application and set restart options after app termination.

Windows OS features

Windows 10 and later OS releases provide a wide variety of APIs related to app lifecycle and system services for apps. These features are available via a combination of WinRT and Win32 (C++ and COM) APIs provided by the Windows SDK.

WinRT APIs

The following articles provide information about features available via WinRT APIs provided by the Windows SDK.

Expand table

Article	Description
Use app services and extensions	Learn how to integrate app services into your Windows app to allow the sharing of data and functionality across apps.
Support your app with background tasks	Learn how make lightweight code run in the background in response to triggers.
Launch an app through file activation	Learn how to set up your app to launch when a file of a certain type is opened.
Launch an app with a URI	Learn how to use a Uniform Resource Identifier (URI) to launch one app from another app, enabling helpful app-to-app scenarios.
Threading and async programming	Learn how to use the thread pool to accomplish work asynchronously in parallel threads.

Win32 (C++ and COM) APIs

The following articles provide information about features available via Win32 (C++ and COM) APIs provided by the Windows SDK.

Expand table

Article	Description
System services	Learn about system services available to apps, including COM, Windows messaging, service applications, and much more.
Memory management	Learn how to use virtual memory, memory mapped files, copy-on-write memory, large memory support, and other memory related features in your app.
Processes and threads	Learn how to control processes, threads, jobs, and other units of code execution in your app.

Article	Description
Windows system information	Learn how to access system information including the registry, handles and objects, and more.

.NET features

The .NET SDK also provides APIs related to system services for WPF and Windows Forms apps.

Threading model (WPF)	Learn about the threading model of WPF apps.
System information	Learn how to access system information in Windows Forms apps.

Windows App SDK app lifecycle

Article • 02/01/2023

This article provides an overview of managing the lifecycle of **Windows App SDK** desktop apps.

App lifecycle overview

The application lifecycle of a Windows App SDK app is not that same as a UWP app. The lifecycle of Windows App SDK apps is similar to other .NET and Win32 desktop apps. Windows App SDK apps, like UWP apps, are started and stopped. They are either running or not running. However, unlike UWP apps, they cannot be suspended and resumed. At the window level, your app can subscribe to events to react when windows are activated and deactivated.

Microsoft.UI.Xaml.Application lifecycle

The Application object is the main entry point for a Windows App SDK app. It's similar to the UWP Application class, but with some important differences. The `Application` object is created by the Windows App SDK framework and is accessible from the `Microsoft.UI.Xaml.Application.Current` property.

The `Application` class in Windows App SDK has only one lifecycle method, OnLaunched, which is called when the app is launched. The `OnLaunched` method is responsible for creating the app's main window and displaying it. The `OnLaunched` method is also responsible for initializing the Windows App SDK framework and starting the app. When you create a new Windows App SDK app, the `OnLaunched` method is automatically generated for you.

In contrast, the UWP `Application` class has several activation-related lifecycle methods, including OnLaunched, OnActivated, and OnBackgroundActivated. The `OnActivated` and `OnBackgroundActivated` methods are called when the app is activated. The `OnActivated` method is called when the app is activated by the user, and the `OnBackgroundActivated` method is called when the app is activated by the system.

UWP's `Application` class also has several lifecycle events: Suspending, Resuming, EnteredBackground, and LeavingBackground. The `Suspending` event is raised when the app is suspended, and the `Resuming` event is raised when the app is resumed. The `EnteredBackground` event is raised when the app enters the background, and the

`LeavingBackground` event is raised when the app leaves the background. For a full explanation of UWP lifecycle events, see Windows 10 UWP app lifecycle.

If you are migrating a UWP app to Windows App SDK, you can use the Application lifecycle functionality migration guide to understand the differences between the UWP and Windows App SDK app lifecycles.

Microsoft.UI.Xaml.Window lifecycle

The Window object in Windows App SDK has some lifecycle events as well, `Window.Activated` and `Window.Closed`.

Window.Activated

The Activated event is raised when the window has been activated or deactivated by the system. Apps can determine what the status of the Window activation is by checking the WindowActivationState property of the WindowActivatedEventArgs parameter. This event will fire any time the window is activated or deactivated, including when the window is minimized or maximized.

Window.Closed

The Closed event is raised when the window closes. If this is the last window to be closed, usually the app's MainWindow, the application will be terminated. Because there is no `Suspending` event raised by the `Application` object in Windows App SDK, you should use your main window's `Closed` event to save application state and clean up any managed resources.

App instancing with the app lifecycle API

Article • 09/20/2024

An app's instancing model determines whether multiple instances of your app's process can run at the same time. The app lifecycle API in the Windows App SDK provides a way to control how many instances of your app can run at the same time, and to redirect activations to other instances when necessary.

This article describes how to use the app lifecycle API to control app instancing in your WinUI apps.

Prerequisites

To use the app lifecycle API in WinUI 3 apps:

- Download and install the latest release of the Windows App SDK. For more information, see Get started with WinUI.
- Follow the instructions to Create your first WinUI 3 project or to use the Windows App SDK in an existing project.

Single-instance apps

Apps are single-instanced if there can be only one main process running at a time. Attempting to launch a second instance of a single-instanced app typically results in the first instance's main window being activated instead. Note that this only applies to the main process. Single-instanced apps can create multiple background processes and still be considered single instanced.

WinUI apps are multi-instanced by default but have the ability to become single-instanced by deciding at launch-time whether to create a new instance or activate an existing instance instead.

The Microsoft Photos app is a good example of a single instanced WinUI app. When you launch Photos for the first time, a new window will be created. If you attempt to launch Photos again, the existing window will be activated instead.

For an example of how to implement single instancing in a WinUI 3 app with C#, see Create a single-instanced WinUI app.

Multi-instanced apps

Apps are multi-instanced if the main process can be run multiple times simultaneously. Attempting to launch a second instance of a multi-instanced app creates a new process and main window.

Traditionally, unpackaged apps are multi-instanced by default, but can implement single-instancing when necessarily. Typically this is done using a single named mutex to indicate if an app is already running.

Notepad is a good example of a multi instanced app. Each time you attempt to launch Notepad, a new instance of Notepad will be created regardless of how many instances are already running.

How the Windows App SDK instancing differs from UWP instancing

Instancing behavior in the Windows App SDK is based on UWP's model, class, but with some key differences:

AppInstance class

- **UWP**: The Windows.ApplicationModel.AppInstance class is focused purely on instance redirection scenarios.
- **Windows App SDK**: The Microsoft.Windows.AppLifeycle.AppInstance class supports instance redirection scenarios, and contains additional functionality to support new features in later releases.

List of instances

- **UWP**: GetInstances returns only the instances that the app explicitly registered for potential redirection.
- **Windows App SDK**: GetInstances returns all running instances of the app that are using the AppInstance API, whether or not they have registered a key. This can include the current instance. If you want the current instance to be included in the list, call `AppInstance.GetCurrent`. Separate lists are maintained for different versions of the same app, as well as instances of apps launched by different users.

Registering keys

Each instance of a multi-instanced app can register an arbitrary key via the `FindOrRegisterForKey` method. Keys have no inherent meaning; apps can use keys in whatever form or way they wish.

An instance of an app can set its key at any time, but only one key is allowed for each instance; setting a new value overwrites the previous value.

An instance of an app cannot set its key to the same value that another instance has already registered. Attempting to register an existing key will result in `FindOrRegisterForKey` returning the app instance that has already registered that key.

- **UWP**: An instance must register a key in order to be included in the list returned from GetInstances.
- **Windows App SDK**: Registering a key is decoupled from the list of instances. An instance does not need to register a key in order to be included in the list.

Unregistering keys

An instance of an app can unregister its key.

- **UWP**: When an instance unregisters its key, it is no longer available for activation redirection and is not included in the list of instances returned from GetInstances.
- **Windows App SDK**: An instance that has unregistered its key is still available for activation redirection and is still included in the list of instances returned from GetInstances.

Instance redirection targets

Multiple instances of an app can activate each other, a process called "activation redirection". For example, an app might implement single instancing by only initializing itself if no other instances of the app are found at startup, and instead redirect and exit if another instance exists. Multi-instanced apps can redirect activations when appropriate according to that app's business logic. When an activation is redirected to another instance, it uses that instance's `Activated` callback, the same callback that's used in all other activation scenarios.

- **UWP**: Only instances that have registered a key can be a target for redirection.
- **Windows App SDK**: Any instance can be a redirection target, whether or not it has a registered key.

Post-redirection behavior

- **UWP**: Redirection is a terminal operation; the app is terminated after redirecting the activation, even if the redirect failed.
- **Windows App SDK**: In the Windows App SDK, redirection is not a terminal operation. This in part reflects the potential problems in arbitrarily terminating a Win32 app that may have already allocated some memory, but also allows support of more sophisticated redirection scenarios. Consider a multi-instanced app where an instance receives an activation request while performing a large amount of CPU-intensive work. That app can redirect the activation request to another instance and continue its processing. That scenario would not be possible if the app was terminated after redirection.

An activation request can be redirected multiple times. Instance A could redirect to instance B, which could in turn redirect to instance C. Windows App SDK apps taking advantage of this functionality must guard against circular redirection - if C redirects to A in the example above, there is a potential infinite activation loop. It is up to the app to determine how to handle circular redirection depending on what makes sense for the workflows that app supports.

Activation events

In order to handle reactivation, the app can register for an Activated event.

- **UWP**: The event passes an IActivatedEventArgs to the app.
- **Windows App SDK**: The event passes a Microsoft.Windows.AppLifecycle.AppActivationArguments instance to the app, which contains one of the `-ActivatedEventArgs` instances.

Examples

Handling activations

This example demonstrates how an app registers for and handles an `Activated` event. When it receives an `Activated` event, this app uses the event arguments to determine what sort of action caused the activation, and responds appropriately.

C++

```
int APIENTRY wWinMain(
    _In_ HINSTANCE hInstance, _In_opt_ HINSTANCE hPrevInstance,
    _In_ LPWSTR lpCmdLine, _In_ int nCmdShow)
{
```

```
    UNREFERENCED_PARAMETER(hPrevInstance);
    UNREFERENCED_PARAMETER(lpCmdLine);

    // Initialize the Windows App SDK framework package for unpackaged apps.
    HRESULT hr{ MddBootstrapInitialize(majorMinorVersion, versionTag,
minVersion) };
    if (FAILED(hr))
    {
        OutputFormattedDebugString(
            L"Error 0x%X in MddBootstrapInitialize(0x%08X, %s,
%hu.%hu.%hu.%hu)\n",
            hr, majorMinorVersion, versionTag,
            minVersion.Major, minVersion.Minor, minVersion.Build,
minVersion.Revision);
        return hr;
    }

    if (DecideRedirection())
    {
        return 1;
    }

    // Connect the Activated event, to allow for this instance of the app
    // getting reactivated as a result of multi-instance redirection.
    AppInstance thisInstance = AppInstance::GetCurrent();
    auto activationToken = thisInstance.Activated(
        auto_revoke, [&thisInstance](
            const auto& sender, const AppActivationArguments& args)
        { OnActivated(sender, args); }
    );

    // Carry on with regular Windows initialization.
    LoadStringW(hInstance, IDS_APP_TITLE, szTitle, MAX_LOADSTRING);
    LoadStringW(hInstance, IDC_CLASSNAME, szWindowClass, MAX_LOADSTRING);
    RegisterWindowClass(hInstance);
    if (!InitInstance(hInstance, nCmdShow))
    {
        return FALSE;
    }

    MSG msg;
    while (GetMessage(&msg, nullptr, 0, 0))
    {
        TranslateMessage(&msg);
        DispatchMessage(&msg);
    }

    MddBootstrapShutdown();
    return (int)msg.wParam;
}

void OnActivated(const IInspectable&, const AppActivationArguments& args)
{
    int const arraysize = 4096;
    WCHAR szTmp[arraysize];
```

```
    size_t cbTmp = arraysize * sizeof(WCHAR);
    StringCbPrintf(szTmp, cbTmp, L"OnActivated (%d)", activationCount++);

    ExtendedActivationKind kind = args.Kind();
    if (kind == ExtendedActivationKind::Launch)
    {
        ReportLaunchArgs(szTmp, args);
    }
    else if (kind == ExtendedActivationKind::File)
    {
        ReportFileArgs(szTmp, args);
    }
}
```

Redirection logic based on activation kind

In this example, the app registers a handler for the Activated event, and also checks for the activation event args to decide whether to redirect activation to another instance.

For most types of activations, the app continues with its regular initialization process. However, if the activation was caused by an associated file type being opened, and if another instance of this app already has the file opened, the current instance will redirect the activation to the existing instance and exit.

This app uses key registration to determine which files are open in which instances. When an instance opens a file, it registers a key that includes that filename. Other instances can then examine the registered keys and look for particular filenames, and register themselves as that file's instance if no other instance already has.

Note that, though key registration itself is part of the app lifecycle API in the Windows App SDK's, the contents of the key are specified only within the app itself. An app does not need to register a file name, or any other meaningful data. This app, however, has decided to track open files via keys based on its particular needs and supported workflows.

C++

```
bool DecideRedirection()
{
    // Get the current executable filesystem path, so we can
    // use it later in registering for activation kinds.
    GetModuleFileName(NULL, szExePath, MAX_PATH);
    wcscpy_s(szExePathAndIconIndex, szExePath);
    wcscat_s(szExePathAndIconIndex, L",1");

    // Find out what kind of activation this is.
    AppActivationArguments args =
AppInstance::GetCurrent().GetActivatedEventArgs();
```

```
    ExtendedActivationKind kind = args.Kind();
    if (kind == ExtendedActivationKind::Launch)
    {
        ReportLaunchArgs(L"WinMain", args);
    }
    else if (kind == ExtendedActivationKind::File)
    {
        ReportFileArgs(L"WinMain", args);

        try
        {
            // This is a file activation: here we'll get the file
information,
            // and register the file name as our instance key.
            IFileActivatedEventArgs fileArgs =
args.Data().as<IFileActivatedEventArgs>();
            if (fileArgs != NULL)
            {
                IStorageItem file = fileArgs.Files().GetAt(0);
                AppInstance keyInstance =
AppInstance::FindOrRegisterForKey(file.Name());
                OutputFormattedMessage(
                    L"Registered key = %ls", keyInstance.Key().c_str());

                // If we successfully registered the file name, we must be
the
                // only instance running that was activated for this file.
                if (keyInstance.IsCurrent())
                {
                    // Report successful file name key registration.
                    OutputFormattedMessage(
                        L"IsCurrent=true; registered this instance for %ls",
                        file.Name().c_str());
                }
                else
                {
                    keyInstance.RedirectActivationToAsync(args).get();
                    return true;
                }
            }
        }
        catch (...)
        {
            OutputErrorString(L"Error getting instance information");
        }
    }
    return false;
}
```

Arbitrary redirection

This example expands on the previous example by adding more sophisticated redirection rules. The app still performs the open file check from the previous example. However, where the previous example would always create a new instance if it did not redirect based on the open file check, this example adds the concept of a "reusable" instance. If a reusable instance is found, the current instance redirects to the reusable instance and exits. Otherwise, it registers itself as reusable and continues with its normal initialization.

Again, note that the concept of a "reusable" instance does not exist in the app lifecycle API; it is created and used only within the app itself.

C++

```
int APIENTRY wWinMain(
    _In_ HINSTANCE hInstance, _In_opt_ HINSTANCE hPrevInstance,
    _In_ LPWSTR lpCmdLine, _In_ int nCmdShow)
{
    // Initialize COM.
    winrt::init_apartment();

    AppActivationArguments activationArgs =
        AppInstance::GetCurrent().GetActivatedEventArgs();

    // Check for any specific activation kind we care about.
    ExtendedActivationKind kind = activationArgs.Kind;
    if (kind == ExtendedActivationKind::File)
    {
        // etc... as in previous scenario.
    }
    else
    {
        // For other activation kinds, we'll trawl all instances to see if
        // any are suitable for redirecting this request. First, get a list
        // of all running instances of this app.
        auto instances = AppInstance::GetInstances();

        // In the simple case, we'll redirect to any other instance.
        AppInstance instance = instances.GetAt(0);

        // If the app re-registers re-usable instances, we can filter for
these instead.
        // In this example, the app uses the string "REUSABLE" to indicate
to itself
        // that it can redirect to a particular instance.
        bool isFound = false;
        for (AppInstance instance : instances)
        {
            if (instance.Key == L"REUSABLE")
            {
                isFound = true;
                instance.RedirectActivationToAsync(activationArgs).get();
```

```
                break;
            }
        }
        if (!isFound)
        {
            // We'll register this as a reusable instance, and then
            // go ahead and do normal initialization.
            winrt::hstring szKey = L"REUSABLE";
            AppInstance::FindOrRegisterForKey(szKey);
            RegisterClassAndStartMessagePump(hInstance, nCmdShow);
        }
    }
    return 1;
}
```

Redirection orchestration

This example again adds more sophisticated redirection behavior. Here, an app instance can register itself as the instance that handles all activations of a specific kind. When an instance of an app receives a `Protocol` activation, it first checks for an instance that has already registered to handle `Protocol` activations. If it finds one, it redirects the activation to that instance. If not, the current instance registers itself for `Protocol` activations, and then applies additional logic (not shown) which may redirect the activation for some other reason.

C++

```
void OnActivated(const IInspectable&, const AppActivationArguments& args)
{
    const ExtendedActivationKind kind = args.Kind;

    // For example, we might want to redirect protocol activations.
    if (kind == ExtendedActivationKind::Protocol)
    {
        auto protocolArgs = args.Data().as<ProtocolActivatedEventArgs>();
        Uri uri = protocolArgs.Uri();

        // We'll try to find the instance that handles protocol activations.
        // If there isn't one, then this instance will take over that duty.
        auto instance =
AppInstance::FindOrRegisterForKey(uri.AbsoluteUri());
        if (!instance.IsCurrent)
        {
            instance.RedirectActivationToAsync(args).get();
        }
        else
        {
            DoSomethingWithProtocolArgs(uri);
        }
    }
```

```
    else
    {
        // In this example, this instance of the app handles all other
        // activation kinds.
        DoSomethingWithNewActivationArgs(args);
    }
}
```

Unlike the UWP version of `RedirectActivationTo`, the Windows App SDK's implementation of RedirectActivationToAsync requires explicitly passing event arguments when redirecting activations. This is necessary because whereas UWP tightly controls activations and can ensure the correct activation arguments are passed to the correct instances, the Windows App SDK's version supports many platforms, and cannot rely on UWP-specific features. One benefit of this model is that apps that use the Windows App SDK have the chance to modify or replace the arguments that will be passed to the target instance.

Redirection without blocking

Most apps will want to redirect as early as possible, before doing unnecessary initialization work. For some app types, initialization logic runs on an STA thread, which must not be blocked. AppInstance.RedirectActivationToAsync method is asynchronous, and the calling app must wait for the method to complete, otherwise the redirection will fail. However, waiting on an async call will block the STA. In these situations, call RedirectActivationToAsync in another thread, and set an event when the call completes. Then wait on that event using non-blocking APIs such as CoWaitForMultipleObjects. Here's a C# sample for a WPF app.

C#

```
private static bool DecideRedirection()
{
    bool isRedirect = false;

    // Find out what kind of activation this is.
    AppActivationArguments args =
AppInstance.GetCurrent().GetActivatedEventArgs();
    ExtendedActivationKind kind = args.Kind;
    if (kind == ExtendedActivationKind.File)
    {
        try
        {
            // This is a file activation: here we'll get the file
information,
            // and register the file name as our instance key.
            if (args.Data is IFileActivatedEventArgs fileArgs)
            {
```

```
                IStorageItem file = fileArgs.Files[0];
                AppInstance keyInstance =
AppInstance.FindOrRegisterForKey(file.Name);

                // If we successfully registered the file name, we must be
the
                // only instance running that was activated for this file.
                if (keyInstance.IsCurrent)
                {
                    // Hook up the Activated event, to allow for this
instance of the app
                    // getting reactivated as a result of multi-instance
redirection.
                    keyInstance.Activated += OnActivated;
                }
                else
                {
                    isRedirect = true;

                    // Ensure we don't block the STA, by doing the redirect
operation
                    // in another thread, and using an event to signal when
it has completed.
                    redirectEventHandle = CreateEvent(IntPtr.Zero, true,
false, null);
                    if (redirectEventHandle != IntPtr.Zero)
                    {
                        Task.Run(() =>
                        {

keyInstance.RedirectActivationToAsync(args).AsTask().Wait();
                            SetEvent(redirectEventHandle);
                        });
                        uint CWMO_DEFAULT = 0;
                        uint INFINITE = 0xFFFFFFFF;
                        _ = CoWaitForMultipleObjects(
                            CWMO_DEFAULT, INFINITE, 1,
                            new IntPtr[] { redirectEventHandle }, out uint
handleIndex);
                    }
                }
            }
        }
        catch (Exception ex)
        {
            Debug.WriteLine($"Error getting instance information:
{ex.Message}");
        }
    }

    return isRedirect;
}
```

Unregister for redirection

Apps that have registered a key can unregister that key at any time. This example assumes the current instance had previously registered a key indicating that it had a specific file opened, meaning subsequent attempts to open that file would be redirected to it. When that file is closed, the key that contains the filename must be deleted.

C++

```
void CALLBACK OnFileClosed(HWND hDlg, UINT message, WPARAM wParam, LPARAM
lParam)
{
    AppInstance::GetCurrent().UnregisterKey();
}
```

> ⚠ **Warning**
>
> Although keys are automatically unregistered when their process terminates, race conditions are possible where another instance may have initiated a redirection to the terminated instance before the terminated instance was unregistered. To mitigate this possibility, an app can use UnregisterKey to manually unregister its key before it is terminated, giving the app a chance to redirect activations to another app that is not in the process of exiting.

Instance information

The Microsoft.Windows.AppLifeycle.AppInstance class represents a single instance of an app. In the current preview, `AppInstance` only includes the methods and properties necessary to support activation redirection. In later releases, `AppInstance` will expand to include other methods and properties relevant to an app instance.

C++

```
void DumpExistingInstances()
{
    for (AppInstance const& instance : AppInstance::GetInstances())
    {
        std::wostringstream sStream;
        sStream << L"Instance: ProcessId = " << instance.ProcessId
            << L", Key = " << instance.Key().c_str() << std::endl;
        ::OutputDebugString(sStream.str().c_str());
    }
}
```

Microsoft.Windows.AppLifeycle.AppInstance

Create a single-instanced WinUI app with C#

Article • 09/20/2024

This how-to demonstrates how to create a single-instanced WinUI 3 app with C# and the Windows App SDK. Single-instanced apps only allow one instance of the app running at a time. WinUI apps are multi-instanced by default. They allow you to launch multiple instances of the same app simultaneously. That's referred to a multiple instances. However, you may want to implement single-instancing based on the use case of your app. Attempting to launch a second instance of a single-instanced app will only result in the first instance's main window being activated instead. This tutorial demonstrates how to implement single-instancing in a WinUI app.

In this article, you will learn how to:

- ✓ Turn off XAML's generated `Program` code
- ✓ Define customized `Main` method for redirection
- ✓ Test single-instancing after app deployment

Pre-requisites

This tutorial uses Visual Studio and builds on the WinUI blank app template. If you're new to WinUI development, you can get set up by following the instructions in Get started with WinUI. There you'll install Visual Studio, configure it for developing apps with WinUI while ensuring you have the latest version of WinUI and the Windows App SDK, and create a Hello World project.

When you've done that, come back here to learn how to turn your "Hello World" project into a single-instanced app.

> ⓘ **Note**
>
> This how-to is based on the Making the app single-instanced (Part 3) blog post from a Windows blog series on WinUI 3. The code for those articles is available on GitHub.

Disable auto-generated Program code

We need to check for redirection as early as possible, before creating any windows. To do this, we must define the symbol “DISABLE_XAML_GENERATED_MAIN” in the project file. Follow these steps to disable the auto-generated Program code:

1. Right-click on the project name in Solution Explorer and select **Edit Project File**.
2. Define the **DISABLE_XAML_GENERATED_MAIN** symbol. Add the following XML to the project file:

```
XML

<PropertyGroup>

<DefineConstants>$(DefineConstants);DISABLE_XAML_GENERATED_MAIN</Define
Constants>
</PropertyGroup>
```

Adding the **DISABLE_XAML_GENERATED_MAIN** symbol will disable the auto-generated Program code for your project.

Define a Program class with a Main method

A customized Program.cs file must be created instead of running the default Main method. The code added to the **Program** class enables the app to check for redirection, which isn't the default behavior of WinUI apps.

1. Navigate to Solution Explorer, right-click on the project name, and select **Add | Class**.
2. Name the new class `Program.cs` and select **Add**.
3. Add the following namespaces to the Program class, replacing any existing namespaces:

```
C#

using System;
using System.Diagnostics;
using System.Runtime.InteropServices;
using System.Threading;
using System.Threading.Tasks;
using Microsoft.UI.Dispatching;
using Microsoft.UI.Xaml;
using Microsoft.Windows.AppLifecycle;
```

4. Replace the empty **Program** class with the following:

C#

```
public class Program
{
    [STAThread]
    static int Main(string[] args)
    {
        WinRT.ComWrappersSupport.InitializeComWrappers();
        bool isRedirect = DecideRedirection();

        if (!isRedirect)
        {
            Application.Start((p) =>
            {
                var context = new
DispatcherQueueSynchronizationContext(
                    DispatcherQueue.GetForCurrentThread());

SynchronizationContext.SetSynchronizationContext(context);
                _ = new App();
            });
        }

        return 0;
    }
}
```

The **Main** method determines whether the app should redirect to the first instance or start a new instance after calling **DecideRedirection**, which we will define next.

5. Define the **DecideRedirection** method below the **Main** method:

C#

```
private static bool DecideRedirection()
{
    bool isRedirect = false;
    AppActivationArguments args =
AppInstance.GetCurrent().GetActivatedEventArgs();
    ExtendedActivationKind kind = args.Kind;
    AppInstance keyInstance =
AppInstance.FindOrRegisterForKey("MySingleInstanceApp");

    if (keyInstance.IsCurrent)
    {
        keyInstance.Activated += OnActivated;
    }
    else
    {
        isRedirect = true;
        RedirectActivationTo(args, keyInstance);
    }
```

```
    return isRedirect;
}
```

DecideRedirection determines if the app has been registered by registering a unique key that represents your app instance. Based on the result of key registration, it can determine if there's a current instance of the app running. After making the determination, the method knows whether to redirect or allow the app to continue launching the new instance. The **RedirectActivationTo** method is called if redirection is necessary.

6. Next, let's create the RedirectActivationTo method below the DecideRedirection method, along with the required DllImport statements. Add the following code to the Program class:

C#

```
[DllImport("kernel32.dll", CharSet = CharSet.Unicode)]
private static extern IntPtr CreateEvent(
    IntPtr lpEventAttributes, bool bManualReset,
    bool bInitialState, string lpName);

[DllImport("kernel32.dll")]
private static extern bool SetEvent(IntPtr hEvent);

[DllImport("ole32.dll")]
private static extern uint CoWaitForMultipleObjects(
    uint dwFlags, uint dwMilliseconds, ulong nHandles,
    IntPtr[] pHandles, out uint dwIndex);

[DllImport("user32.dll")]
static extern bool SetForegroundWindow(IntPtr hWnd);

private static IntPtr redirectEventHandle = IntPtr.Zero;

// Do the redirection on another thread, and use a non-blocking
// wait method to wait for the redirection to complete.
public static void RedirectActivationTo(AppActivationArguments args,
                                        AppInstance keyInstance)
{
    redirectEventHandle = CreateEvent(IntPtr.Zero, true, false, null);
    Task.Run(() =>
    {
        keyInstance.RedirectActivationToAsync(args).AsTask().Wait();
        SetEvent(redirectEventHandle);
    });

    uint CWMO_DEFAULT = 0;
    uint INFINITE = 0xFFFFFFFF;
    _ = CoWaitForMultipleObjects(
       CWMO_DEFAULT, INFINITE, 1,
```

```
        [redirectEventHandle], out uint handleIndex);

    // Bring the window to the foreground
    Process process =
Process.GetProcessById((int)keyInstance.ProcessId);
    SetForegroundWindow(process.MainWindowHandle);
}
```

The **RedirectActivationTo** method is responsible for redirecting the activation to the first instance of the app. It creates an event handle, starts a new thread to redirect the activation, and waits for the redirection to complete. After the redirection is complete, the method brings the window to the foreground.

7. Finally, define the helper method **OnActivated** below the **DecideRedirection** method:

```
C#

private static void OnActivated(object sender, AppActivationArguments
args)
{
    ExtendedActivationKind kind = args.Kind;
}
```

Test single-instancing via app deployment

Until this point, we've been testing the app by debugging within Visual Studio. However, we can only have one debugger running at once. This limitation prevents us from knowing whether the app is single-instanced because we can’t debug the same project twice at the same time. For an accurate test, we'll deploy the application to our local Windows client. After deploying, we can launch the app from the desktop like you would with any app installed on Windows.

1. Navigate to Solution Explorer, right-click on the project name, and select **Deploy**.
2. Open the Start menu and click into the search field.
3. Type your app's name in the search field.
4. Click the app icon from the search result to launch your app.

> ⓘ **Note**
>
> If you experience app crashes in release mode, there are some known issues with trimmed apps in the Windows App SDK. You can disable trimming in the

project by setting the **PublishTrimmed** property to **false** for all build configurations in your project's `.pubxml` files. For more information, see this issue on GitHub.

5. Repeat steps 2 to 4 to launch the same app again and see if another instance opens. If the app is single-instanced, the first instance will be activated instead of a new instance opening.

> **Tip**
>
> You can optionally add some logging code to the **OnActivated** method to verify that the existing instance has been activated. Try asking **Copilot** for help with adding an **ILogger implementation** to your WinUI app.

Summary

All the code covered here is on GitHub, with branches for the different steps in the original Windows blog series. See the single-instancing branch for code specific to this how-to. The `main` branch is the most comprehensive. The other branches are intended to show you how the app architecture evolved.

Rich activation with the app lifecycle API

Article • 03/07/2024

In the Windows App SDK, the app lifecycle API brings support for UWP-style rich activation behavior to all apps, packaged and unpackaged alike. This first release focuses on bringing the most commonly-used activation kinds to unpackaged apps, and future releases aim to support more of UWP's 44 activation kinds.

Supporting rich activations requires two steps:

- Tell the system that your app supports one or more rich activation kinds.
- Receive and process the rich activation payloads your app receives when it is activated.

Prerequisites

To use the app lifecycle API in the Windows App SDK:

1. Download and install the latest release of the Windows App SDK. For more information, see Get started with WinUI.
2. Follow the instructions to Create your first WinUI 3 project or to use the Windows App SDK in an existing project.

Activation details for unpackaged apps

The current version of the Windows App SDK supports the four most common activation kinds to unpackaged apps. These activation kinds are defined by the ExtendedActivationKind enum.

Expand table

Activation kind	Description
`Launch`	Activate the app from the command line, when the user double-clicks the app's icon, or programmatically via ShellExecute or CreateProcess.
`File`	Activate an app that has registered for a file type when a file of the type is opened via ShellExecute, Launcher.LaunchFileAsync, or the command line.
`Protocol`	Activate an app that has registered for a protocol when a string of that protocol is executed via ShellExecute, Launcher.LaunchUriAsync, or the command-line.

Activation kind	Description
`StartupTask`	Activate the app when the user logs into Windows, either because of a registry key, or because of a shortcut in a well-known startup folder.

Each type of unpackaged app retrieves its command line arguments in different ways. For example, C++ Win32 apps expect to receive activation arguments to be passed into `WinMain` in the form of a string (though they also have the option to call GetCommandLineW). Windows Forms apps, however, *must* call Environment.GetCommandLineArgs, because arguments will not be automatically passed to them.

Activation details for packaged apps

Packaged apps that use the Windows App SDK support all 44 of UWP's activation kinds. Each activation kind has its own corresponding implementation of IActivatedEventArgs which contain properties relevant to that specific kind of activation.

Packaged apps will always receive activation event arguments in their AppInstance.Activated event handler, and also have the option of calling AppInstance.GetActivatedEventArgs.

Activation registration

All apps support the `Launch` activation kind by default. Unlike UWP, the Windows App SDK `Launch` activation kind includes command line launches. Apps can register for additional activation kinds in several ways.

- Unpackaged apps that use the Windows App SDK can register (and unregister) for additional activation kinds via the app lifecycle API in the Windows App SDK.
- Unpackaged apps can continue to register for additional activation kinds using the traditional method of writing registry keys.
- Packaged apps can register for additional activation kinds via entries in their application manifest.

Activation registrations are per-user. If your app is installed for multiple users, you will need to re-register activations for each user.

Examples

Register for rich activation

Although apps can call the registration APIs at any time, the most common scenario is checking registrations on app startup.

This example shows how an unpackaged app can use the following static methods of the ActivationRegistrationManager class to register for several activation kinds when the app is launched:

- RegisterForFileTypeActivation
- RegisterForProtocolActivation
- RegisterForStartupActivation

This example also demonstrates how to use the MddBootstrapInitialize and MddBootstrapShutdown functions to initialize and clean up references to the Windows App SDK framework package. All unpackaged app must do this to use APIs provided by the Windows App SDK. For more information, see Use the Windows App SDK runtime for apps packaged with external location or unpackaged.

> **Note**
>
> This example registers associations with three image file types at once. This is convenient, but the outcome is the same as registering each file type individually; registering new image types does not overwrite previous registrations. However, if an app re-registers an already registered file type with a different set of verbs, the previous set of verbs will be overwritten for that file type.

c++

```
const UINT32 majorMinorVersion{ WINDOWSAPPSDK_RELEASE_MAJORMINOR };
PCWSTR versionTag{ WINDOWSAPPSDK_RELEASE_VERSION_TAG_W };
const PACKAGE_VERSION minVersion{ WINDOWSAPPSDK_RUNTIME_VERSION_UINT64 };
WCHAR szExePath[MAX_PATH]{};
WCHAR szExePathAndIconIndex[MAX_PATH + 8]{};

int APIENTRY wWinMain(
    _In_ HINSTANCE hInstance, _In_opt_ HINSTANCE hPrevInstance,
    _In_ LPWSTR lpCmdLine, _In_ int nCmdShow)
{
    UNREFERENCED_PARAMETER(hPrevInstance);
    UNREFERENCED_PARAMETER(lpCmdLine);

    // Initialize Windows App SDK framework package for unpackaged apps.
    HRESULT hr{ MddBootstrapInitialize(majorMinorVersion, versionTag,
minVersion) };
    if (FAILED(hr))
```

```
    {
        wprintf(L"Error 0x%X in MddBootstrapInitialize(0x%08X, %s,
%hu.%hu.%hu.%hu)\n",
            hr, majorMinorVersion, versionTag, minVersion.Major,
            minVersion.Minor, minVersion.Build, minVersion.Revision);
        return hr;
    }

    // Get the current executable filesystem path, so we can
    // use it later in registering for activation kinds.
    GetModuleFileName(NULL, szExePath, MAX_PATH);
    wcscpy_s(szExePathAndIconIndex, szExePath);
    wcscat_s(szExePathAndIconIndex, L",1");

    LoadStringW(hInstance, IDS_APP_TITLE, szTitle, MAX_LOADSTRING);
    LoadStringW(hInstance, IDC_CLASSNAME, szWindowClass, MAX_LOADSTRING);
    RegisterWindowClass(hInstance);
    if (!InitInstance(hInstance, nCmdShow))
    {
        return FALSE;
    }

    MSG msg;
    while (GetMessage(&msg, nullptr, 0, 0))
    {
        TranslateMessage(&msg);
        DispatchMessage(&msg);
    }

    // Uninitialize Windows App SDK.
    MddBootstrapShutdown();
    return (int)msg.wParam;
}

void RegisterForActivation()
{
    OutputMessage(L"Registering for rich activation");

    // Register one or more supported filetypes, specifying
    // an icon (specified by binary file path plus resource index),
    // a display name to use in Shell and Settings,
    // zero or more verbs for the File Explorer context menu,
    // and the path to the EXE to register for activation.
    hstring myFileTypes[3] = { L".foo", L".foo2", L".foo3" };
    hstring verbs[2] = { L"view", L"edit" };
    ActivationRegistrationManager::RegisterForFileTypeActivation(
        myFileTypes,
        szExePathAndIconIndex,
        L"Contoso File Types",
        verbs,
        szExePath
    );

    // Register a URI scheme for protocol activation,
    // specifying the scheme name, icon, display name and EXE path.
```

```
    ActivationRegistrationManager::RegisterForProtocolActivation(
        L"foo",
        szExePathAndIconIndex,
        L"Contoso Foo Protocol",
        szExePath
    );

    // Register for startup activation.
    // As we're registering for startup activation multiple times,
    // and this is a multi-instance app, we'll get multiple instances
    // activated at startup.
    ActivationRegistrationManager::RegisterForStartupActivation(
        L"ContosoStartupId",
        szExePath
    );

    // If we don't specify the EXE, it will default to this EXE.
    ActivationRegistrationManager::RegisterForStartupActivation(
        L"ContosoStartupId2",
        L""
    );
}
```

Get rich activation event arguments

Once activated, an app must retrieve its activation event arguments. In this example, an unpackaged app calls the AppInstance.GetActivatedEventArgs method to get the event args for the activation event and then uses the AppActivationArguments.Kind property to retrieve the event args for different types of activations.

> ⓘ **Note**
>
> Win32 apps typically get command-line arguments very early their `WinMain` method. Similarly, these apps should call AppInstance.GetActivatedEventArgs in the same place where they previously would have used the supplied the `lpCmdLine` parameter or called `GetCommandLineW`.

```
c++

void GetActivationInfo()
{
    AppActivationArguments args =
AppInstance::GetCurrent().GetActivatedEventArgs();
    ExtendedActivationKind kind = args.Kind();
    if (kind == ExtendedActivationKind::Launch)
    {
        ILaunchActivatedEventArgs launchArgs =
```

```
            args.Data().as<ILaunchActivatedEventArgs>();
        if (launchArgs != NULL)
        {
            winrt::hstring argString = launchArgs.Arguments().c_str();
            std::vector<std::wstring> argStrings = split_strings(argString);
            OutputMessage(L"Launch activation");
            for (std::wstring s : argStrings)
            {
                OutputMessage(s.c_str());
            }
        }
    }
    else if (kind == ExtendedActivationKind::File)
    {
        IFileActivatedEventArgs fileArgs =
            args.Data().as<IFileActivatedEventArgs>();
        if (fileArgs != NULL)
        {
            IStorageItem file = fileArgs.Files().GetAt(0);
            OutputFormattedMessage(
                L"File activation: %s", file.Name().c_str());
        }
    }
    else if (kind == ExtendedActivationKind::Protocol)
    {
        IProtocolActivatedEventArgs protocolArgs =
            args.Data().as<IProtocolActivatedEventArgs>();
        if (protocolArgs != NULL)
        {
            Uri uri = protocolArgs.Uri();
            OutputFormattedMessage(
                L"Protocol activation: %s", uri.RawUri().c_str());
        }
    }
    else if (kind == ExtendedActivationKind::StartupTask)
    {
        IStartupTaskActivatedEventArgs startupArgs =
            args.Data().as<IStartupTaskActivatedEventArgs>();
        if (startupArgs != NULL)
        {
            OutputFormattedMessage(
                L"Startup activation: %s", startupArgs.TaskId().c_str());
        }
    }
}
```

Unregister

This example demonstrates how an unpackaged app can unregister for specific activation kinds dynamically, using the following static methods of the ActivationRegistrationManager class:

- UnregisterForFileTypeActivation
- UnregisterForProtocolActivation
- UnregisterForStartupActivation

> **Note**
>
> When unregistering for startup activation, the app must use the same taskId that it used when it originally registered.

c++

```
void UnregisterForActivation()
{
    OutputMessage(L"Unregistering for rich activation");

    // Unregister one or more registered filetypes.
    try
    {
        hstring myFileTypes[3] = { L".foo", L".foo2", L".foo3" };
        ActivationRegistrationManager::UnregisterForFileTypeActivation(
            myFileTypes,
            szExePath
        );
    }
    catch (...)
    {
        OutputMessage(L"Error unregistering file types");
    }

    // Unregister a protocol scheme.
    ActivationRegistrationManager::UnregisterForProtocolActivation(
        L"foo",
        L"");

    // Unregister for startup activation.
    ActivationRegistrationManager::UnregisterForStartupActivation(
        L"ContosoStartupId");
    ActivationRegistrationManager::UnregisterForStartupActivation(
        L"ContosoStartupId2");
}
```

Power management with the app lifecycle API

Article • 03/07/2024

The app lifecycle API in the Windows App SDK provides a set of power management APIs in the Microsoft.Windows.System.Power namespace. These APIs provide visibility into how an app affects the device's power state, and they enable the app to make intelligent decisions about resource usage. For example, an app might use this API to postpone resource-intensive background tasks while the device is running on battery power.

The power management APIs use a callback-based model similar to the existing PowerSettingRegisterNotification function. Using a callback model extends the reach of the API to all apps, including background apps, headless apps, and others.

Prerequisites

To use the app lifecycle API in the Windows App SDK:

1. Download and install the latest release of the Windows App SDK. For more information, see Get started with WinUI.
2. Follow the instructions to Create your first WinUI 3 project or to use the Windows App SDK in an existing project.

Subscribe and respond to events

The following example demonstrates how to subscribe and respond to PowerManager events. This code subscribes to the BatteryStatusChanged event during startup. The app then responds to changes by checking the current power level and adjusting its resource usage appropriately. For example, if the battery discharges at a low power state, the app might defer any non-critical background work.

C++/WinRT

> **Note**

Apps can register and unregister for these events at any time, but most apps will want to set callbacks in `WinMain` that persist as long as the app continues to run.

C++

```
BOOL bWorkInProgress;
winrt::event_token batteryToken;
winrt::event_token powerToken;
winrt::event_token powerSourceToken;
winrt::event_token chargeToken;
winrt::event_token dischargeToken;

void RegisterPowerManagerCallbacks()
{
    batteryToken = PowerManager::BatteryStatusChanged([&](
        const auto&, winrt::Windows::Foundation::IInspectable obj) {
OnBatteryStatusChanged(); });
    powerToken = PowerManager::PowerSupplyStatusChanged([&](
        const auto&, winrt::Windows::Foundation::IInspectable obj) {
OnPowerSupplyStatusChanged(); });
    powerSourceToken = PowerManager::PowerSourceKindChanged([&](
        const auto&, winrt::Windows::Foundation::IInspectable obj) {
OnPowerSourceKindChanged(); });
    chargeToken = PowerManager::RemainingChargePercentChanged([&](
        const auto&, winrt::Windows::Foundation::IInspectable obj) {
OnRemainingChargePercentChanged(); });
    dischargeToken = PowerManager::RemainingDischargeTimeChanged([&](
        const auto&, winrt::Windows::Foundation::IInspectable obj) {
OnRemainingDischargeTimeChanged(); });

    if (batteryToken && powerToken && powerSourceToken && chargeToken &&
dischargeToken)
    {
        OutputMessage(L"Successfully registered for state
notifications");
    }
    else
    {
        OutputMessage(L"Failed to register for state notifications");
    }
}

void OnBatteryStatusChanged()
{
    const size_t statusSize = 16;
    WCHAR szStatus[statusSize];
    wmemset(&(szStatus[0]), 0, statusSize);

    BatteryStatus batteryStatus = PowerManager::BatteryStatus();
    int remainingCharge = PowerManager::RemainingChargePercent();
    switch (batteryStatus)
```

```
    {
    case BatteryStatus::Charging:
        wcscpy_s(szStatus, L"Charging");
        break;
    case BatteryStatus::Discharging:
        wcscpy_s(szStatus, L"Discharging");
        break;
    case BatteryStatus::Idle:
        wcscpy_s(szStatus, L"Idle");
        break;
    case BatteryStatus::NotPresent:
        wcscpy_s(szStatus, L"NotPresent");
        break;
    }

    OutputFormattedMessage(
        L"Battery status changed: %s, %d%% remaining",
        szStatus, remainingCharge);
    DetermineWorkloads();
}

void OnPowerSupplyStatusChanged()
{
//...etc
}
```

Configure app logic based on multiple status values

PowerManager events are relatively low-level, and in some scenarios, a single event handler being called might not provide enough information for the app to decide how to behave. In this example, the PowerSupplyStatusChanged event could be called when the device is disconnected from power. In that case, the app must check the current battery status before deciding how to proceed.

C++/WinRT

C++

```
void DetermineWorkloads()
{
    BatteryStatus batteryStatus = PowerManager::BatteryStatus();
    int remainingCharge = PowerManager::RemainingChargePercent();
    PowerSupplyStatus powerStatus = PowerManager::PowerSupplyStatus();
    PowerSourceKind powerSource = PowerManager::PowerSourceKind();

    if ((powerSource == PowerSourceKind::DC
```

```
        && batteryStatus == BatteryStatus::Discharging
        && remainingCharge < 25)
        || (powerSource == PowerSourceKind::AC
        && powerStatus == PowerSupplyStatus::Inadequate))
    {
        // The device is not in a good battery/power state,
        // so we should pause any non-critical work.
        PauseNonCriticalWork();
    }
    else if ((batteryStatus != BatteryStatus::Discharging &&
remainingCharge > 75)
        && powerStatus != PowerSupplyStatus::Inadequate)
    {
        // The device is in good battery/power state,
        // so let's kick of some high-power work.
        StartPowerIntensiveWork();
    }
}
```

Check screen status

The PowerManager class offers information about other device states relevant to an app's power usage. For example, apps can disable graphics processing when the device's display is turned off.

C++/WinRT

C++

```
void OnDisplayStatusChanged()
{
    const size_t statusSize = 16;
    WCHAR szStatus[statusSize];
    wmemset(&(szStatus[0]), 0, statusSize);

    DisplayStatus displayStatus = PowerManager::DisplayStatus();
    switch (displayStatus)
    {
    case DisplayStatus::Dimmed:
        wcscpy_s(szStatus, L"Dimmed");
        break;
    case DisplayStatus::Off:
        wcscpy_s(szStatus, L"Off");
        break;
    case DisplayStatus::On:
        wcscpy_s(szStatus, L"On");
        break;
    }
```

```
    OutputFormattedMessage(
        L"Display status changed: %s", szStatus);
    if (displayStatus == DisplayStatus::Off)
    {
        // The screen is off, let's stop rendering foreground graphics,
        // and instead kick off some background work now.
        StopUpdatingGraphics();
        StartDoingBackgroundWork();
    }
}
```

Unsubscribe from events

Apps can register and deregister for notifications during their lifecycle. Use your language's preferred event registration management system if your app doesn't need to receive power status notifications during its entire lifecycle.

C++/WinRT

C++

```
void UnregisterPowerManagerCallbacks()
{
    OutputMessage(L"Unregistering state notifications");
    PowerManager::BatteryStatusChanged(batteryToken);
    PowerManager::PowerSupplyStatusChanged(powerToken);
    PowerManager::PowerSourceKindChanged(powerSourceToken);
    PowerManager::RemainingChargePercentChanged(chargeToken);
    PowerManager::RemainingDischargeTimeChanged(dischargeToken);
}
```

Detect and react to focus session state

Article • 07/27/2022

Windows 11 introduced the Focus feature which helps users minimize distractions by turning on Do Not Disturb and silencing icon flashing and badge notifications for apps in the taskbar. This article shows you how to use the FocusSessionManager API to detect whether a Focus session is currently active or receive updates when the Focus session state changes, allowing you to customize your app's behavior to minimize distractions when a Focus session is active. For more information on the Focus feature, see How to use focus in Windows 11.

Get the current Focus session state

Before accessing the properties of the **FocusSessionManager**, make sure it's supported on the current device by checking the IsSupported property. After verifying that the feature is supported you can determine if a Focus session is currently active by checking the IsFocusActive property.

C#

```
private void UpdateStatusBar(string message)
{
    var focusActive = false;
    if (Windows.UI.Shell.FocusSessionManager.IsSupported)
    {
        var manager = Windows.UI.Shell.FocusSessionManager.GetDefault();
        focusActive = manager.IsFocusActive;
    }

    if (!focusActive)
    {
        statusTextBlock.Text = message;
    }
}
```

Continuously monitor focus state

You can subscribe to be notified when the Focus session state on the device changes by registering for the IsFocusActiveChanged event. In the following example **SetAnimatedGifAutoPlay** is an app-implemented helper method that changes whether the app auto-plays animated gifs based on the current Focus session state.

C#

```
protected override void OnNavigatedTo(NavigationEventArgs e)
{
    if (Windows.UI.Shell.FocusSessionManager.IsSupported)
    {
        var manager = Windows.UI.Shell.FocusSessionManager.GetDefault();
        manager.IsFocusActiveChanged += Manager_IsFocusActiveChanged;
        SetAnimatedGifAutoPlay(true);
    }
}

private void
Manager_IsFocusActiveChanged(Windows.UI.Shell.FocusSessionManager
sender, object args)
{
    if(sender.IsFocusActive)
    {
        SetAnimatedGifAutoPlay(true);
    }
    else
    {
        SetAnimatedGifAutoPlay(false);
    }
}
```

Launching Windows apps and managing background tasks

Article • 03/19/2025

Learn how to use a Uniform Resource Identifier (URI) or a file type to launch a Windows app or manage background tasks in your apps.

Launch a Windows app with a URI

This section describes how to use a URI to launch your Windows app.

Handle file activation in a Windows app

Article • 02/13/2025

Your app can register to become the default handler for a certain file type. Both Windows desktop applications and Universal Windows Platform (UWP) apps can register to be a default file handler. If the user chooses your app as the default handler for a certain file type, your app will be activated when that type of file is launched.

We recommend that you only register for a file type if you expect to handle all file launches for that type of file. If your app only needs to use the file type internally, then you don't need to register to be the default handler. If you do choose to register for a file type, you must provide the end user with the functionality that is expected when your app is activated for that file type. For example, a picture viewer app may register to display a .jpg file. For more info on file associations, see Guidelines for file types and URIs.

These steps show how to register for a custom file type, .alsdk, and how to activate your app when the user launches an .alsdk file.

> **Note**
>
> In Windows, certain URIs and file extensions are reserved for use by built-in apps and the operating system. Attempts to register your app with a reserved URI or file extension will be ignored. See Reserved URI scheme names and file types for an alphabetic list of Uri schemes that you can't register for your apps because they are either reserved or forbidden.

Important APIs

The following APIs are used in this topic:

- Windows.ApplicationModel.Activation.FileActivatedEventArgs
- Windows.UI.Xaml.Application.OnFileActivated
- AppInstance.GetActivatedEventArgs

Step 1: Specify the extension point in the package manifest

The app receives activation events only for the file extensions listed in the package manifest. Here's how you indicate that your app handles the files with the `.alsdk` extension.

1. In the **Solution Explorer**, double-click package.appxmanifest to open the manifest designer. Select the **Declarations** tab and in the **Available Declarations** drop-down, select **File Type Associations** and then click **Add**. See Programmatic Identifiers for more details of identifiers used by file associations.

   Here is a brief description of each of the fields that you may fill in the manifest designer:

Expand table

Field	Description
Display Name	Specify the display name for a group of file types. The display name is used to identify the file type in the Set Default Programs on the **Control Panel**.
Logo	Specify the logo that is used to identify the file type on the desktop and in the Set Default Programs on the **Control Panel**. If no Logo is specified, the application's small logo is used.
Info Tip	Specify the info tip for a group of file types. This tool tip text appears when the user hovers on the icon for a file of this type.
Name	Choose a name for a group of file types that share the same display name, logo, info tip, and edit flags. Choose a group name that can stay the same across app updates. **Note** The Name must be in all lower case letters.
Content Type	Specify the MIME content type, such as **image/jpeg**, for a particular file type. **Important Note about allowed content types:** Here is an alphabetic list of MIME content types that you cannot enter into the package manifest because they are either reserved or forbidden: **application/force-download**, **application/octet-stream**, **application/unknown**, **application/x-msdownload**.
File type	Specify the file type to register for, preceded by a period, for example, ".jpeg". **Reserved and forbidden file types:** See Reserved URI scheme names and file types for an alphabetic list of file types for built-in apps that you can't register for your UWP apps because they are either reserved or forbidden.

2. Enter `alsdk` as the **Name**.
3. Enter `.alsdk` as the **File Type**.
4. Enter "images\Icon.png" as the Logo.
5. Press Ctrl+S to save the change to package.appxmanifest.

The steps above add an Extension element like this one to the package manifest. The **windows.fileTypeAssociation** category indicates that the app handles files with the `.alsdk` extension.

XML

```
      <Extensions>
        <uap:Extension Category="windows.fileTypeAssociation">
          <uap:FileTypeAssociation Name="alsdk">
            <uap:Logo>images\icon.png</uap:Logo>
            <uap:SupportedFileTypes>
              <uap:FileType>.alsdk</uap:FileType>
            </uap:SupportedFileTypes>
          </uap:FileTypeAssociation>
        </uap:Extension>
      </Extensions>
```

Step 2: Add the proper icons

Apps that become the default for a file type have their icons displayed in various places throughout the system. For example, these icons are shown in:

- Windows Explorer Items View, context menus, and the Ribbon
- Default programs Control Panel
- File picker
- Search results on the Start screen

Include a 44x44 icon with your project so that your logo can appear in those locations. Match the look of the app tile logo and use your app's background color rather than making the icon transparent. Have the logo extend to the edge without padding it. Test your icons on white backgrounds. See Guidelines for tile and icon assets for more details about icons.

Step 3: Handle the activated event

The OnFileActivated event handler receives all file activation events.

C#

```
protected override void OnFileActivated(FileActivatedEventArgs args)
{
       // TODO: Handle file activation
       // The number of files received is args.Files.Count
```

```
        // The name of the first file is args.Files[0].Name
}
```

> **Note**
>
> When launched via File Contract, make sure that Back button takes the user back to the screen that launched the app and not to the app's previous content.

> **Note**
>
> In a WinUI app, in App.OnLaunched (or in fact at any time) you can call (AppInstance.GetActivatedEventArgs) to retrieve the activated event args, and check them to determine how the app was activated. See Application lifecycle functionality migration for more information about lifecycle differences between UWP and WinUI apps.

We recommend that you create a new XAML **Frame** for each activation event that opens a new page. That way, the navigation backstack for the new XAML Frame doesn't contain any previous content that the app might have on the current window when suspended. If you decide to use a single XAML **Frame** for Launch and for File Contracts, then you should clear the pages in the **Frame**'s navigation journal before navigating to a new page.

When your app is launched via File activation, you should consider including UI that allows the user to go back to the top page of the app.

Remarks

The files that you receive could come from an untrusted source. We recommend that you validate the content of a file before taking action on it.

Launch the default app for a file

Article • 02/13/2025

Learn how to launch the default app for a file from your WinUI, Universal Windows Platform (UWP), or other desktop app. Many apps need to work with files that they can't handle themselves. For example, e-mail apps receive a variety of file types and need a way to launch these files in their default handlers. These steps show how to use the Windows.System.Launcher Windows Runtime (WinRT) API to launch the default handler for a file that your app can't handle itself.

Important APIs

The following APIs are featured in this topic:

- Windows.System.Launcher.LaunchFileAsync

> **Note**
>
> Unless noted otherwise, all the WinRT APIs used in this topic can be used in both UWP apps, WinUI apps, and other desktop apps. To read more about enabling your desktop app to work with WinRT APIs, see **Call Windows Runtime APIs in desktop apps**.

Get the file object

First, get a Windows.Storage.StorageFile object for the file.

If the file is included in the package for your app, you can use the Package.InstalledLocation property to get a Windows.Storage.StorageFolder object and the Windows.Storage.StorageFolder.GetFileAsync method to get the StorageFile object.

If the file is in a known folder, you can use the properties of the Windows.Storage.KnownFolders class to get a StorageFolder and the GetFileAsync method to get the StorageFile object.

Launch the file

Windows provides several different options for launching the default handler for a file. These options are described in this chart and in the sections that follow.

Expand table

Option	Method	Description
Default launch	LaunchFileAsync(IStorageFile)	Launch the specified file with the default handler.
Open With launch	LaunchFileAsync(IStorageFile, LauncherOptions)	Launch the specified file letting the user pick the handler through the Open With dialog.
Launch with a recommended app fallback	LaunchFileAsync(IStorageFile, LauncherOptions)	Launch the specified file with the default handler. If no handler is installed on the system, recommend an app in the store to the user.
Launch with a desired remaining view	LaunchFileAsync(IStorageFile, LauncherOptions) (Windows-only)	Launch the specified file with the default handler. Specify a preference to stay on screen after the launch and request a specific window size. LauncherOptions.DesiredRemainingView isn't supported on the mobile device family.

Default launch

Call the Windows.System.Launcher.LaunchFileAsync(IStorageFile) method to launch the default app. This example uses the Windows.Storage.StorageFolder.GetFileAsync method to launch an image file, test.png, that is included in the app package.

C#

```
async void DefaultLaunch()
{
   // Path to the file in the app package to launch
   string imageFile = @"images\test.png";

   var file = await
Windows.ApplicationModel.Package.Current.InstalledLocation.GetFileAsync(imag
eFile);

   if (file != null)
   {
      // Launch the retrieved file
      var success = await Windows.System.Launcher.LaunchFileAsync(file);

      if (success)
      {
         // File launched
      }
      else
      {
         // File launch failed
```

```
      }
   }
   else
   {
      // Could not find file
   }
}
```

C++/WinRT

```
Windows::Foundation::IAsyncAction MainPage::DefaultLaunch()
{
    auto installFolder{
Windows::ApplicationModel::Package::Current().InstalledLocation() };

    Windows::Storage::StorageFile file{ co_await
installFolder.GetFileAsync(L"images\\test.png") };

    if (file)
    {
        // Launch the retrieved file
        bool success = co_await
Windows::System::Launcher::LaunchFileAsync(file);
        if (success)
        {
            // File launched
        }
        else
        {
            // File launch failed
        }
    }
    else
    {
        // Could not find file
    }
}
```

C++

```
void MainPage::DefaultLaunch()
{
   auto installFolder = Windows::ApplicationModel::Package::Current-
>InstalledLocation;

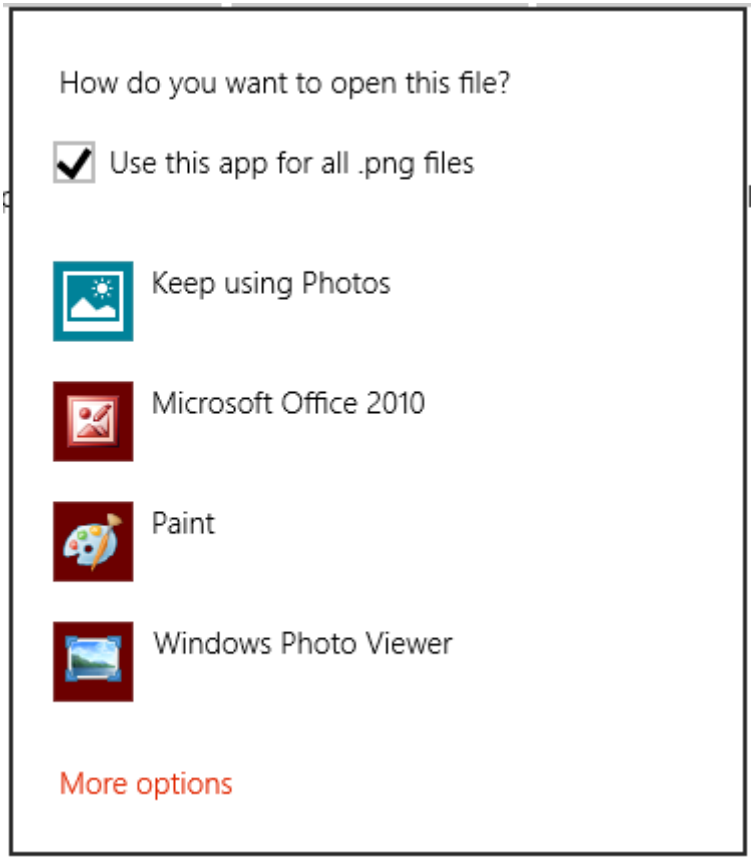
concurrency::task<Windows::Storage::StorageFile^getFileOperation(installFold
er->GetFileAsync("images\\test.png"));
   getFileOperation.then([](Windows::Storage::StorageFile^ file)
   {
      if (file != nullptr)
      {
```

```
            // Launch the retrieved file
            concurrency::task<bool>
    launchFileOperation(Windows::System::Launcher::LaunchFileAsync(file));
            launchFileOperation.then([](bool success)
            {
               if (success)
               {
                  // File launched
               }
               else
               {
                  // File launch failed
               }
            });
         }
         else
         {
            // Could not find file
         }
      });
   }
```

Open With launch

Call the Windows.System.Launcher.LaunchFileAsync(IStorageFile, LauncherOptions) method with LauncherOptions.DisplayApplicationPicker set to **true** to launch the app that the user selects from the **Open With** dialog box.

We recommend that you use the **Open With** dialog box when the user may want to select an app other than the default for a particular file. For example, if your app allows the user to launch an image file, the default handler will likely be a viewer app. In some cases, the user may want to edit the image instead of viewing it. Use the **Open With** option along with an alternative command in the **AppBar** or in a context menu to let the user bring up the **Open With** dialog and select the editor app in these types of scenarios.



C#

```
async void DefaultLaunch()
{
   // Path to the file in the app package to launch
      string imageFile = @"images\test.png";

   var file = await
Windows.ApplicationModel.Package.Current.InstalledLocation.GetFileAsync(imag
eFile);

   if (file != null)
   {
      // Set the option to show the picker
      var options = new Windows.System.LauncherOptions();
      options.DisplayApplicationPicker = true;

      // Launch the retrieved file
      bool success = await Windows.System.Launcher.LaunchFileAsync(file,
options);
      if (success)
      {
         // File launched
      }
      else
      {
         // File launch failed
      }
   }
   else
```

```
    {
        // Could not find file
    }
}
```

C++/WinRT

```
Windows::Foundation::IAsyncAction MainPage::DefaultLaunch()
{
    auto installFolder{
Windows::ApplicationModel::Package::Current().InstalledLocation() };

    Windows::Storage::StorageFile file{ co_await
installFolder.GetFileAsync(L"images\\test.png") };

    if (file)
    {
        // Set the option to show the picker
        Windows::System::LauncherOptions launchOptions;
        launchOptions.DisplayApplicationPicker(true);

        // Launch the retrieved file
        bool success = co_await
Windows::System::Launcher::LaunchFileAsync(file, launchOptions);
        if (success)
        {
            // File launched
        }
        else
        {
            // File launch failed
        }
    }
    else
    {
        // Could not find file
    }
}
```

C++

```
void MainPage::DefaultLaunch()
{
    auto installFolder = Windows::ApplicationModel::Package::Current-
>InstalledLocation;

    concurrency::task<Windows::Storage::StorageFile^>
getFileOperation(installFolder->GetFileAsync("images\\test.png"));
    getFileOperation.then([](Windows::Storage::StorageFile^ file)
    {
        if (file != nullptr)
        {
```

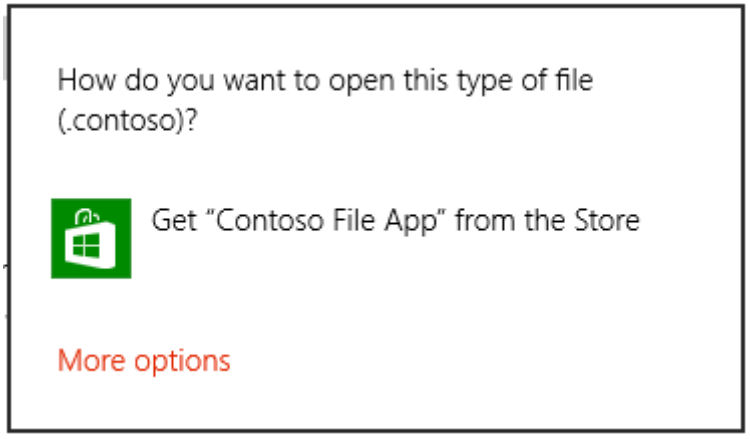
```
            // Set the option to show the picker
            auto launchOptions = ref new Windows::System::LauncherOptions();
            launchOptions->DisplayApplicationPicker = true;

            // Launch the retrieved file
            concurrency::task<bool>
launchFileOperation(Windows::System::Launcher::LaunchFileAsync(file,
launchOptions));
            launchFileOperation.then([](bool success)
            {
               if (success)
               {
                  // File launched
               }
               else
               {
                  // File launch failed
               }
            });
         }
         else
         {
            // Could not find file
         }
      });
}
```

Launch with a recommended app fallback

In some cases the user may not have an app installed to handle the file that you are launching. By default, Windows will handle these cases by providing the user with a link to search for an appropriate app on the store. If you would like to give the user a specific recommendation for which app to acquire in this scenario, you may do so by passing that recommendation along with the file that you are launching. To do this, call the Windows.System.Launcher.launchFileAsync(IStorageFile, LauncherOptions) method with LauncherOptions.PreferredApplicationPackageFamilyName set to the package family name of the app in the Store that you want to recommend. Then, set the LauncherOptions.PreferredApplicationDisplayName to the name of that app. Windows will use this information to replace the general option to search for an app in the store with a specific option to acquire the recommended app from the Store.

> **Note**
>
> You must set both of these options to recommend an app. Setting one without the other will result in a failure.



C#

```
async void DefaultLaunch()
{
   // Path to the file in the app package to launch
   string imageFile = @"images\test.contoso";

   // Get the image file from the package's image directory
   var file = await
Windows.ApplicationModel.Package.Current.InstalledLocation.GetFileAsync(imag
eFile);

   if (file != null)
   {
      // Set the recommended app
      var options = new Windows.System.LauncherOptions();
      options.PreferredApplicationPackageFamilyName =
"Contoso.FileApp_8wknc82po1e";
      options.PreferredApplicationDisplayName = "Contoso File App";

      // Launch the retrieved file pass in the recommended app
      // in case the user has no apps installed to handle the file
      bool success = await Windows.System.Launcher.LaunchFileAsync(file,
options);
      if (success)
      {
         // File launched
      }
      else
      {
         // File launch failed
      }
   }
   else
   {
      // Could not find file
   }
}
```

C++/WinRT

```
Windows::Foundation::IAsyncAction MainPage::DefaultLaunch()
{
    auto installFolder{
Windows::ApplicationModel::Package::Current().InstalledLocation() };

    Windows::Storage::StorageFile file{ co_await
installFolder.GetFileAsync(L"images\\test.png") };

    if (file)
    {
        // Set the recommended app
        Windows::System::LauncherOptions launchOptions;

launchOptions.PreferredApplicationPackageFamilyName(L"Contoso.FileApp_8wknc8
2po1e");
        launchOptions.PreferredApplicationDisplayName(L"Contoso File App");

        // Launch the retrieved file, and pass in the recommended app
        // in case the user has no apps installed to handle the file.
        bool success = co_await
Windows::System::Launcher::LaunchFileAsync(file, launchOptions);
        if (success)
        {
            // File launched
        }
        else
        {
            // File launch failed
        }
    }
    else
    {
        // Could not find file
    }
}
```

C++

```
void MainPage::DefaultLaunch()
{
   auto installFolder = Windows::ApplicationModel::Package::Current-
>InstalledLocation;

   concurrency::task<Windows::Storage::StorageFile^>
getFileOperation(installFolder->GetFileAsync("images\\test.contoso"));
   getFileOperation.then([](Windows::Storage::StorageFile^ file)
   {
      if (file != nullptr)
      {
         // Set the recommended app
         auto launchOptions = ref new Windows::System::LauncherOptions();
         launchOptions->PreferredApplicationPackageFamilyName =
```

```
"Contoso.FileApp_8wknc82po1e";
        launchOptions->PreferredApplicationDisplayName = "Contoso File
App";

        // Launch the retrieved file pass, and in the recommended app
        // in case the user has no apps installed to handle the file.
        concurrency::task<bool>
launchFileOperation(Windows::System::Launcher::LaunchFileAsync(file,
launchOptions));
        launchFileOperation.then([](bool success)
        {
           if (success)
           {
              // File launched
           }
           else
           {
              // File launch failed
           }
        });
     }
     else
     {
        // Could not find file
     }
  });
}
```

Launch with a Desired Remaining View (UWP-only)

Source apps that call LaunchFileAsync can request that they remain on screen after a file launch. By default, Windows attempts to share all available space equally between the source app and the target app that handles the file. Source apps can use the DesiredRemainingView property to indicate to the operating system that they prefer their app window to take up more or less of the available space. **DesiredRemainingView** can also be used to indicate that the source app does not need to remain on screen after the file launch and can be completely replaced by the target app. This property only specifies the preferred window size of the calling app. It doesn't specify the behavior of other apps that may happen to also be on screen at the same time.

> ⓘ **Note**
>
> Windows takes into account multiple different factors when it determines the source app's final window size, for example, the preference of the source app, the number of apps on screen, the screen orientation, and so on. By setting

DesiredRemainingView, you aren't guaranteed a specific windowing behavior for the source app.

C#

```
async void DefaultLaunch()
{
   // Path to the file in the app package to launch
   string imageFile = @"images\test.png";

   var file = await
Windows.ApplicationModel.Package.Current.InstalledLocation.GetFileAsync(imag
eFile);

   if (file != null)
   {
      // Set the desired remaining view
      var options = new Windows.System.LauncherOptions();
      options.DesiredRemainingView =
Windows.UI.ViewManagement.ViewSizePreference.UseLess;

      // Launch the retrieved file
      bool success = await Windows.System.Launcher.LaunchFileAsync(file,
options);
      if (success)
      {
         // File launched
      }
      else
      {
         // File launch failed
      }
   }
   else
   {
      // Could not find file
   }
}
```

C++/WinRT

```
Windows::Foundation::IAsyncAction MainPage::DefaultLaunch()
{
    auto installFolder{
Windows::ApplicationModel::Package::Current().InstalledLocation() };

    Windows::Storage::StorageFile file{ co_await
installFolder.GetFileAsync(L"images\\test.png") };

    if (file)
    {
```

```
        // Set the desired remaining view.
        Windows::System::LauncherOptions launchOptions;

launchOptions.DesiredRemainingView(Windows::UI::ViewManagement::ViewSizePref
erence::UseLess);

        // Launch the retrieved file.
        bool success = co_await
Windows::System::Launcher::LaunchFileAsync(file, launchOptions);
        if (success)
        {
            // File launched
        }
        else
        {
            // File launch failed
        }
    }
    else
    {
        // Could not find file
    }
}
```

C++

```
void MainPage::DefaultLaunch()
{
   auto installFolder = Windows::ApplicationModel::Package::Current-
>InstalledLocation;

   concurrency::task<Windows::Storage::StorageFile^>
getFileOperation(installFolder->GetFileAsync("images\\test.png"));
   getFileOperation.then([](Windows::Storage::StorageFile^ file)
   {
      if (file != nullptr)
      {
         // Set the desired remaining view.
         auto launchOptions = ref new Windows::System::LauncherOptions();
         launchOptions->DesiredRemainingView =
Windows::UI::ViewManagement::ViewSizePreference::UseLess;

         // Launch the retrieved file.
         concurrency::task<bool>
launchFileOperation(Windows::System::Launcher::LaunchFileAsync(file,
launchOptions));
         launchFileOperation.then([](bool success)
         {
            if (success)
            {
               // File launched
            }
            else
```

```
            {
                // File launch failed
            }
        });
    }
    else
    {
        // Could not find file
    }
});
}
```

Remarks

Your app can't select the app that is launched. The user determines which app is launched. The user can select either a UWP app or a Windows desktop app.

When launching a file, your app must be the foreground app, that is, it must be visible to the user. This requirement helps ensure that the user remains in control. To meet this requirement, make sure that you tie all file launches directly to the UI of your app. Most likely, the user must always take some action to initiate a file launch.

You can't launch file types that contain code or script if they are executed automatically by the operating system, such as, .exe, .msi, and .js files. This restriction protects users from potentially malicious files that could modify the operating system. You can use this method to launch file types that can contain script if they are executed by an app that isolates the script, such as, .docx files. Apps like Microsoft Word keep the script in .docx files from modifying the operating system.

If you try to launch a restricted file type, the launch will fail and your error callback will be invoked. If your app handles many different types of files and you expect that you will hit this error, we recommend that you provide a fallback experience to your user. For example, you could give the user an option to save the file to the desktop, and they could open it there.

Handle URI activation

Article • 02/13/2025

Learn how to register an app to become the default handler for a Uniform Resource Identifier (URI) scheme name. Both Windows desktop apps and Universal Windows Platform (UWP) apps can register to be a default handler for a URI scheme name. If the user chooses your app as the default handler for a URI scheme name, your app will be activated every time that type of URI is launched.

We recommend that you only register for a URI scheme name if you expect to handle all URI launches for that type of URI scheme. If you do choose to register for a URI scheme name, you must provide the end user with the functionality that is expected when your app is activated for that URI scheme. For example, an app that registers for the mailto: URI scheme name should open to a new e-mail message so that the user can compose a new e-mail. For more info on URI associations, see Files, folders, and libraries.

These steps show how to register for a custom URI scheme name, `alsdk://`, and how to activate your app when the user launches a `alsdk://` URI.

Important APIs

The following APIs are used in this topic:

- Windows.ApplicationModel.Activation.ProtocolActivatedEventArgs
- Windows.UI.Xaml.Application.OnActivated
- AppInstance.GetActivatedEventArgs

> **Note**
>
> In Windows, certain URIs and file extensions are reserved for use by built-in apps and the operating system. Attempts to register your app with a reserved URI or file extension will be ignored. See Reserved URI scheme names and file types for an alphabetic list of Uri schemes that you can't register for your apps because they are either reserved or forbidden.

Step 1: Specify the extension point in the package manifest

The app receives activation events only for the URI scheme names listed in the package manifest. Here's how you indicate that your app handles the `alsdk` URI scheme name.

1. In the **Solution Explorer**, double-click package.appxmanifest to open the manifest designer. Select the **Declarations** tab and in the **Available Declarations** drop-down, select **Protocol** and then click **Add**.

   Here is a brief description of each of the fields that you may fill in the manifest designer for the Protocol (see AppX Package Manifest for details):

Expand table

Field	Description
Logo	Specify the logo that is used to identify the URI scheme name in the Set Default Programs on the **Control Panel**. If no Logo is specified, the small logo for the app is used.
Display Name	Specify the display name to identify the URI scheme name in the Set Default Programs on the **Control Panel**.
Name	Choose a name for the Uri scheme.
	Note The Name must be in all lower case letters.
	Reserved and forbidden file types See Reserved URI scheme names and file types for an alphabetic list of Uri schemes that you can't register for your Windows apps because they are either reserved or forbidden.
Executable	Specifies the default launch executable for the protocol. If not specified, the app's executable is used. If specified, the string must be between 1 and 256 characters in length, must end with ".exe", and cannot contain these characters: >, <, :, ", |, ?, or *. If specified, the **Entry point** is also used. If the **Entry point** isn't specified, the entry point defined for the app is used.
Entry point	Specifies the task that handles the protocol extension. This is normally the fully namespace-qualified name of a Windows Runtime type. If not specified, the entry point for the app is used.
Start page	The web page that handles the extensibility point.
Resource group	A tag that you can use to group extension activations together for resource management purposes.
Desired View (Windows-only)	Specify the **Desired View** field to indicate the amount of space the app's window needs when it is launched for the URI scheme name. The possible values for **Desired View** are **Default**, **UseLess**, **UseHalf**, **UseMore**, or **UseMinimum**. **Note** Windows takes into account multiple different factors when determining the target app's final window size, for example, the preference of the source app, the number of apps on screen, the screen orientation, and so on. Setting **Desired**

Field	Description
	View doesn't guarantee a specific windowing behavior for the target app. **Mobile device family: Desired View** isn't supported on the mobile device family.

2. Enter `images\Icon.png` as the **Logo**.
3. Enter `SDK Sample URI Scheme` as the **Display name**
4. Enter `alsdk` as the **Name**.
5. Press Ctrl+S to save the change to package.appxmanifest.

   This adds an Extension element like this one to the package manifest. The **windows.protocol** category indicates that the app handles the `alsdk` URI scheme name.

XML

```
  <Applications>
      <Application Id= ... >
          <Extensions>
              <uap:Extension Category="windows.protocol">
                <uap:Protocol Name="alsdk">
                  <uap:Logo>images\icon.png</uap:Logo>
                  <uap:DisplayName>SDK Sample URI Scheme</uap:DisplayName>
                </uap:Protocol>
              </uap:Extension>
        </Extensions>
        ...
      </Application>
  </Applications>
```

Step 2: Add the proper icons

Apps that become the default for a URI scheme name have their icons displayed in various places throughout the system such as in the Default programs control panel. Include a 44x44 icon with your project for this purpose. Match the look of the app tile logo and use your app's background color rather than making the icon transparent. Have the logo extend to the edge without padding it. Test your icons on white backgrounds. See App icons and logos for more details about icons.

Step 3: Handle the activated event

> **Note**
>
> In a WinUI app, in App.OnLaunched (or in fact at any time) you can call (AppInstance.GetActivatedEventArgs) to retrieve the activated event args, and check them to determine how the app was activated. See Application lifecycle functionality migration for more information about lifecycle differences between UWP and WinUI apps.

In UWP apps, the OnActivated event handler receives all activation events. The **Kind** property indicates the type of activation event. This example is set up to handle Protocol activation events.

C#

```
public partial class App
{
   protected override void OnActivated(IActivatedEventArgs args)
  {
      if (args.Kind == ActivationKind.Protocol)
      {
         ProtocolActivatedEventArgs eventArgs = args as
ProtocolActivatedEventArgs;
         // TODO: Handle URI activation
         // The received URI is eventArgs.Uri.AbsoluteUri
      }
   }
}
```

C++/WinRT

```
void
App::OnActivated(Windows::ApplicationModel::Activation::IActivatedEventArgs
const& args)
{
    if (args.Kind() ==
Windows::ApplicationModel::Activation::ActivationKind::Protocol)
    {
        auto protocolActivatedEventArgs{
args.as<Windows::ApplicationModel::Activation::ProtocolActivatedEventArgs>()
};
        // TODO: Handle URI activation
        auto receivedURI{ protocolActivatedEventArgs.Uri().RawUri() };
    }
}
```

C++

```
void
App::OnActivated(Windows::ApplicationModel::Activation::IActivatedEventArgs^
args)
{
   if (args->Kind ==
Windows::ApplicationModel::Activation::ActivationKind::Protocol)
   {
      Windows::ApplicationModel::Activation::ProtocolActivatedEventArgs^
eventArgs =

dynamic_cast<Windows::ApplicationModel::Activation::ProtocolActivatedEventAr
gs^>(args);

      // TODO: Handle URI activation
      // The received URI is eventArgs->Uri->RawUri
   }
}
```

> **Note**
>
> When launched via Protocol Contract, make sure that Back button takes the user back to the screen that launched the app and not to the app's previous content.

The following code programmatically launches the app via its URI:

C#

```
   // Launch the URI
   var uri = new Uri("alsdk:");
   var success = await Windows.System.Launcher.LaunchUriAsync(uri)
```

For more details about how to launch an app via a URI, see Launch the default app for a URI.

It is recommended that apps create a new XAML Frame for each activation event that opens a new page. This way, the navigation backstack for the new XAML **Frame** will not contain any previous content that the app might have on the current window when suspended. Apps that decide to use a single XAML **Frame** for Launch and File Contracts should clear the pages on the **Frame** navigation journal before navigating to a new page.

When launched via Protocol activation, apps should consider including UI that allows the user to go back to the top page of the app.

Remarks

Any app or website can use your URI scheme name, including malicious ones. So any data that you get in the URI could come from an untrusted source. We recommend that you never perform a permanent action based on the parameters that you receive in the URI. For example, URI parameters could be used to launch the app to a user's account page, but we recommend that you never use them to directly modify the user's account.

> **Note**
>
> If you are creating a new URI scheme name for your app, be sure to follow the guidance in RFC 4395. This ensures that your name meets the standards for URI schemes.

> **Note**
>
> When a UWP app is launched via Protocol Contract, make sure that Back button takes the user back to the screen that launched the app and not to the app's previous content.

We recommend that apps create a new XAML **Frame** for each activation event that opens a new Uri target. This way, the navigation backstack for the new XAML **Frame** will not contain any previous content that the app might have on the current window when suspended.

If you decide that you want your apps to use a single XAML **Frame** for Launch and Protocol Contracts, clear the pages on the **Frame** navigation journal before navigating to a new page. When launched via Protocol Contract, consider including UI into your apps that allows the user to go back to the top of the app.

Launch the default Windows app for a URI

Article • 02/13/2025

Learn how to launch the default app for a Uniform Resource Identifier (URI). URIs allow you to launch another app to perform a specific task. This topic also provides an overview of the many URI schemes built into Windows. You can launch custom URIs too. For more info about registering a custom URI scheme and handling URI activation, see Handle URI activation.

URI schemes let you open apps by clicking hyperlinks. Just as you can start a new email using **mailto:**, you can open the default web browser using **http:** or **https:**.

This topic describes the following URI schemes built into Windows:

Expand table

URI Scheme	Launches
bingmaps:, ms-drive-to:, and ms-walk-to:	Maps app
http: and https:	Default web browser
mailto:	Default email app
microsoft-edge:	Microsoft Edge browser
ms-chat:	Messaging app
ms-people:	People app
ms-photos:	Photos app
ms-recall:	Click to do (part of Recall)
ms-settings:	Settings app
ms-store:	Store app
msnweather:	Weather app

For example, the following URI opens the default browser and displays the Microsoft Bing web site: `https://bing.com/`.

You can also launch custom URI schemes too. If there is no app installed to handle that URI, you can recommend an app for the user to install. For more info, see Recommend

an app if one is not available to handle the URI.

In general, your app can't select the app that is launched. The user determines which app is launched. More than one app can register to handle the same URI scheme. The exception to this is for reserved URI schemes. Registrations of reserved URI schemes are ignored. For the full list of reserved URI schemes, see Handle URI activation. In cases where more than one app may have registered the same URI scheme, your app can recommend a specific app to be launched. For more info, see Recommend an app if one is not available to handle the URI.

Important APIs

The following Windows Runtime (WinRT) APIs are used in this topic:

- LaunchUriAsync
- PreferredApplicationPackageFamilyName
- DesiredRemainingView

Note that many WinRT APIs will work with other desktop apps with package identity. There are some exceptions, and most of these are related to APIs that are specific to UI rendering or input. Some of the **LauncherOptions**, such as TreatAsUntrusted, only work in UWP apps. To read more about enabling your desktop app to work with WinRT APIs, see Call Windows Runtime APIs in desktop apps.

Call LaunchUriAsync to launch a URI

Use the LaunchUriAsync method to launch a URI. When you call this method, your app must be the foreground app, that is, it must be visible to the user. This requirement helps ensure that the user remains in control. To meet this requirement, make sure that you tie all URI launches directly to the UI of your app. The user must always take some action to initiate a URI launch. In a UWP app, if you attempt to launch a URI and your app isn't in the foreground, the launch will fail and your error callback will be invoked.

First create a System.Uri object to represent the URI, then pass that to the LaunchUriAsync method. Use the return result to see if the call succeeded, as shown in the following example.

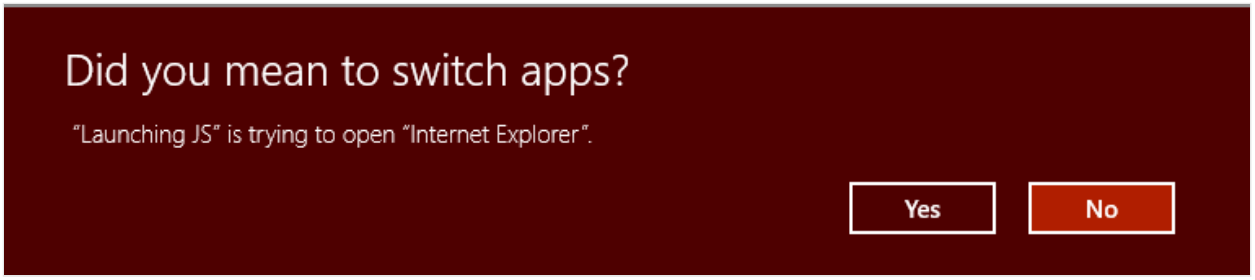
cs

```
private async void launchURI_Click(object sender, RoutedEventArgs e)
{
    // The URI to launch
    var bingUri = new Uri(@"https://www.bing.com");
```

```
    // Launch the URI
    var success = await Windows.System.Launcher.LaunchUriAsync(bingUri);

    if (success)
    {
        // URI launched
    }
    else
    {
        // URI launch failed
    }
}
```

In some cases, the operating system will prompt the user to see if they actually want to switch apps.



> **ⓘ Important**
>
> This prompt is only supported by UWP apps. If Windows attempts to show this prompt for a desktop app, the launch will fail.

If your app is a UWP app, and you always want this prompt to occur, use the Windows.System.LauncherOptions.TreatAsUntrusted property to tell the operating system to display a warning.

cs

```
// The URI to launch
var uriBing = new Uri(@"http://www.bing.com");

// Set the option to show a warning
var promptOptions = new Windows.System.LauncherOptions
{
    TreatAsUntrusted = true
};

// Launch the URI
var success = await Windows.System.Launcher.LaunchUriAsync(uriBing,
promptOptions);
```

Recommend an app if one is not available to handle the URI

In some cases, the user might not have an app installed to handle the URI that you are launching. By default, the operating system handles these cases by providing the user with a link to search for an appropriate app on the store. If you want to give the user a specific recommendation for which app to acquire in this scenario, you can do so by passing that recommendation along with the URI that you are launching.

Recommendations are also useful when more than one app has registered to handle a URI scheme. By recommending a specific app, Windows will open that app if it is already installed.

To make a recommendation, call the Windows.System.Launcher.LaunchUriAsync(Uri, LauncherOptions) method with LauncherOptions.preferredApplicationPackageFamilyName set to the package family name of the app in the store that you want to recommend. The operating system uses this info to replace the general option to search for an app in the store with a specific option to acquire the recommended app from the store.

```cs
// Set the recommended app
var options = new Windows.System.LauncherOptions
{
    PreferredApplicationPackageFamilyName = "Contoso.URIApp_8wknc82po1e",
    PreferredApplicationDisplayName = "Contoso URI App"
};

// Launch the URI and pass in the recommended app
// in case the user has no apps installed to handle the URI
var success = await Windows.System.Launcher.LaunchUriAsync(uriContoso,
options);
```

Set remaining view preference

> **Important**
>
> This feature is only available in UWP apps. When used in a desktop app, the property will be ignored.

Source apps that call LaunchUriAsync can request that they remain on screen after a URI launch. By default, Windows attempts to share all available space equally between the

source app and the target app that handles the URI. Source apps can use the DesiredRemainingView property to indicate to the operating system that they prefer their app window to take up more or less of the available space. **DesiredRemainingView** can also be used to indicate that the source app doesn't need to remain on screen after the URI launch and can be completely replaced by the target app. This property only specifies the preferred window size of the calling app. It doesn't specify the behavior of other apps that may happen to also be on screen at the same time.

> **Note**
>
> Windows takes into account multiple different factors when it determines the source app's final window size, for example, the preference of the source app, the number of apps on screen, the screen orientation, and so on. By setting DesiredRemainingView, you aren't guaranteed a specific windowing behavior for the source app.

cs

```
// Set the desired remaining view.
var options = new Windows.System.LauncherOptions
{
    DesiredRemainingView =
Windows.UI.ViewManagement.ViewSizePreference.UseLess
};

// Launch the URI
var success = await Windows.System.Launcher.LaunchUriAsync(uriContoso,
options);
```

URI Schemes

The various URI schemes are described in this section.

Email URI scheme

Use the **mailto:** URI scheme to launch the default mail app.

Expand table

URI Scheme	Results
`mailto:`	Launches the default email app.

URI Scheme	Results
`mailto:\[email address\]`	Launches the email app and creates a new message with the specified email address on the To line. Note that the email is not sent until the user taps send.

HTTP URI scheme

Use the **http:** URI scheme to launch the default web browser.

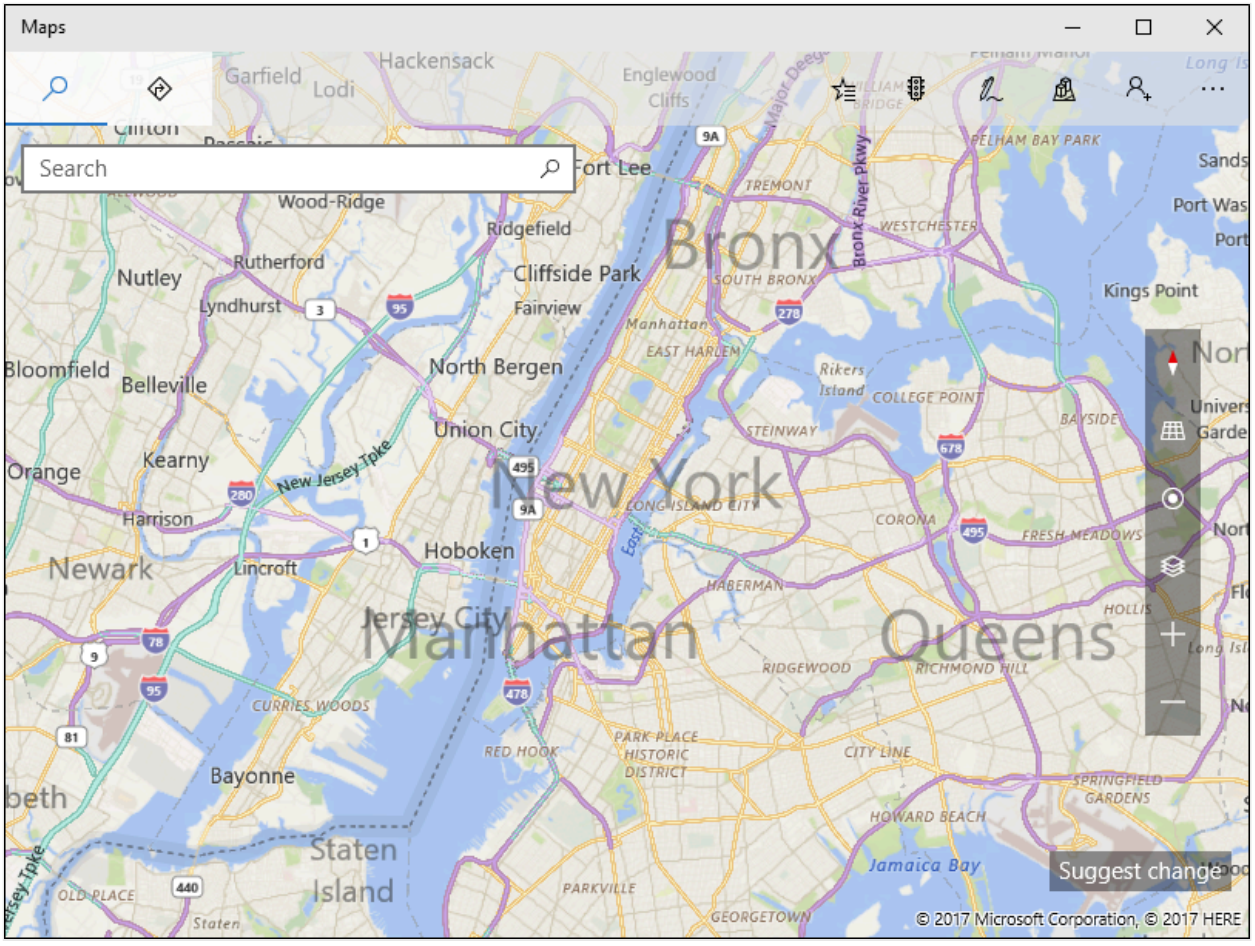
Expand table

URI Scheme	Results
`http:` or `https:`	Launches the default web browser.

Maps app URI schemes

Use the **bingmaps:**, **ms-drive-to:**, and **ms-walk-to:** URI schemes to launch the Windows Maps app to specific maps, directions, and search results. For example, the following URI opens the Windows Maps app and displays a map centered over New York City.

```
bingmaps:?cp=40.726966~-74.006076
```



For more info, see Launch the Windows Maps app. To use the map control in your UWP app, see Display maps with 2D, 3D, and Streetside views. If you're using Windows App SDK 1.5 or later in a WinUI app or other desktop app, you can use the MapControl.

Messaging app URI scheme

Use the **ms-chat:** URI scheme to launch the Microsoft Messaging app.

Expand table

URI scheme	Results
`ms-chat:`	Launches the Messaging app.
`ms-chat:?ContactID={contacted}`	Allows the messaging application to be launched with a particular contact's information.
`ms-chat:?Body={body}`	Allows the messaging application to be launched with a string to use as the content of the message.
`ms-chat:?Addresses={address}&Body={body}`	Allows the messaging application to be launched with a particular addresses' information, and with a string to use as the content of the message. Note: Addresses can be concatenated.
`ms-chat:?TransportId={transportId}`	Allows the messaging application to be launched with a particular transport ID.

People app URI scheme

Use the **ms-people:** URI scheme to launch the People app. For more info, see Launch the People app.

> **Important**
>
> The People app is moving to the new Outlook. You can take your contacts with you by selecting **Export contacts** on the People app's toolbar and then importing them into the new Outlook. See Manage your contacts and connect with people through the new Outlook for Windows (Preview) for more information.

Photos app URI scheme

Use the **ms-photos:** URI scheme to launch the Photos app to view an image or edit a video. For example:

Expand table

Operation	URI
View an image	`ms-photos:viewer?fileName=c:\users\userName\Pictures\image.jpg`
Edit a video	`ms-photos:videoedit?InputToken=123abc&Action=Trim&StartTime=01:02:03`

> **Note**
>
> If you are launching the Photos app from a UWP app, the URIs to edit a video or display an image are only available on desktop.

The following table lists additional supported URI schemes for the Photos app:

Expand table

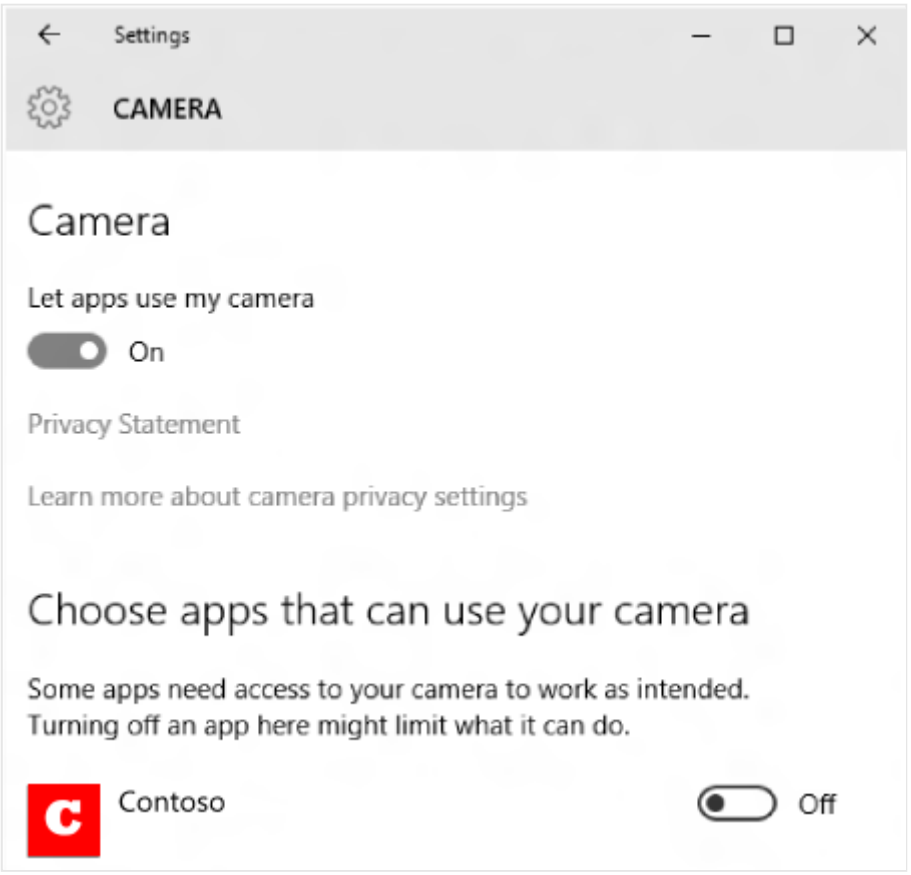
URI scheme	Results
`ms-photos:viewer?fileName={filename}`	Launches the Photos app to view the specified image where {filename} is a fully-qualified path name. For example: `c:\users\userName\Pictures\ImageToView.jpg`
`ms-photos:videoedit?InputToken={input token}`	Launches the Photos app in video editing mode for the file represented by the file token. **InputToken** is required. Use the SharedStorageAccessManager to get a token for a file.
`ms-photos:videoedit?Action={action}`	A parameter that indicates which video editing mode to open the Photos app in, where {action} is one of: **SlowMotion**, **FrameExtraction**, **Trim**, **View**, **Ink**. **Action** is required.
`ms-photos:videoedit?StartTime={timespan}`	An optional parameter that specifies where to start playing the video. `{timespan}` must be in the format `"hh:mm:ss.ffff"`. If not specified, defaults to `00:00:00.0000`

Settings app URI scheme

Use the **ms-settings:** URI scheme to launch the Windows Settings app. Launching to the Settings app is an important part of writing a privacy-aware app. If your app can't access a sensitive resource, we recommend providing the user a convenient link to the privacy settings for that resource.

For example, the following URI opens the Settings app and displays the camera privacy settings:

```
ms-settings:privacy-webcam
```



For more info, see Launch the Windows Settings app and Security and identity.

Store app URI scheme

Use the **ms-windows-store:** URI scheme to launch the Microsoft Store app. Open product detail pages, product review pages, and search pages, etc. For example, the following URI opens the Microsoft Store app and launches the home page of the Store.

```
ms-windows-store://home/
```

For more info, see Using ms-windows-store URIs.

Weather app URI scheme

Use the **msnweather:** URI scheme to launch the Weather app.

Expand table

URI Scheme	Results
`msnweather://forecast?la=\[latitude\]&lo=\[longitude\]`	Launches the Weather app in the Forecast page based on a location geographic coordinates.

URI Scheme	Results
	`latitude` refers to the latitude of the location. `longitude` refers to the longitude of the location.

Microsoft Edge URI scheme

Use the **microsoft-edge:** URI scheme to launch the Microsoft Edge browser to a specified URL.

Expand table

URI Scheme	Results
`microsoft-edge:https://example.com/`	Opens the Microsoft Edge browser and navigates to `https://example.com/`

You can use this URI scheme to launch the Microsoft Edge browser, regardless of the user's default browser setting.

Handle URI activation

Launch the Settings app

Launch the Windows Settings app

Article • 02/13/2025

Learn how to launch the Windows Settings app. This topic describes the `ms-settings:` URI scheme. Use this URI scheme to launch the Windows Settings app to specific settings pages.

Launching to the Settings app is an important part of writing a privacy-aware app. If your app can't access a sensitive resource, we recommend providing the user a convenient link to the privacy settings for that resource. For more information, see Security and identity.

Important APIs

The following Windows Runtime (WinRT) APIs are used in this topic:

- LaunchUriAsync
- PreferredApplicationPackageFamilyName
- DesiredRemainingView

Note that the WinRT APIs used in this topic can be used in both UWP apps, WinUI apps, and other desktop apps. To read more about enabling your desktop app to work with WinRT APIs, see Call Windows Runtime APIs in desktop apps.

How to launch the Settings app

To launch the **Settings** app, use the `ms-settings:` URI scheme as shown in the following examples.

XAML hyperlink control

In this example, a Hyperlink XAML control is used to launch the privacy settings page for the microphone using the `ms-settings:privacy-microphone` URI.

XML

```
<!--Set Visibility to Visible when access to the microphone is denied -->
<TextBlock x:Name="LocationDisabledMessage" FontStyle="Italic"
                Visibility="Collapsed" Margin="0,15,0,0"
TextWrapping="Wrap" >
          <Run Text="This app is not able to access the microphone. Go to "
/>
```

```
            <Hyperlink NavigateUri="ms-settings:privacy-microphone">
                <Run Text="Settings" />
            </Hyperlink>
        <Run Text=" to check the microphone privacy settings."/>
</TextBlock>
```

Calling LaunchUriAsync

Alternatively, your app can call the LaunchUriAsync method to launch the **Settings** app. This example shows how to launch to the privacy settings page for the camera using the `ms-settings:privacy-webcam` URI.

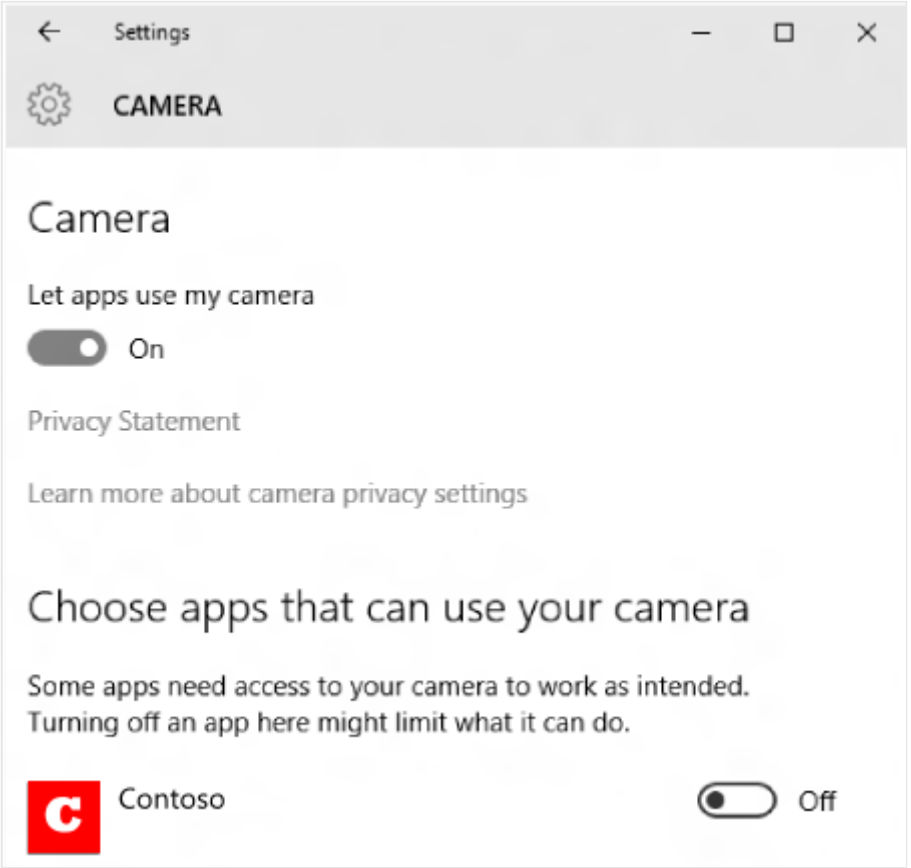
cs

```
bool result = await Windows.System.Launcher.LaunchUriAsync(new Uri("ms-settings:privacy-webcam"));
```

C++/WinRT

```
bool result = co_await Windows::System::Launcher::LaunchUriAsync(Windows::Foundation::Uri(L"ms-settings:privacy-webcam"));
```

The code above launches the privacy settings page for the camera:



For more info about launching URIs, see Launch the default app for a URI.

ms-settings: URI scheme reference

The following sections describe different categories of ms-settings URIs used to open various pages of the Settings app:

- Accounts
- Apps
- Control Center
- Cortana
- Devices
- Ease of access
- Extras
- Family Group
- Gaming
- Mixed reality
- Network and internet
- Personalization
- Phone
- Privacy
- Search
- Sound
- Surface Hub
- System
- Time and language
- Update and security

> **Note**
>
> The availability of some settings pages varies by Windows version and SKU. For some settings, the URI column also captures some usage information and any additional requirements that must be met for a page to be available.

Accounts

Expand table

Settings page	URI
Access work or school	ms-settings:workplace
Email & app accounts	ms-settings:emailandaccounts
Family & other people	ms-settings:otherusers
Provisioning	ms-settings:provisioning (only available on mobile and if the enterprise has deployed a provisioning package) ms-settings:workplace-provisioning (only available if enterprise has deployed a provisioning package)
Repair token	ms-settings:workplace-repairtoken
Set up a kiosk	ms-settings:assignedaccess
Sign-in options	ms-settings:signinoptions ms-settings:signinoptions-dynamiclock
Sync your settings	ms-settings:sync ms-settings:backup (**Backup page deprecated in Windows 11**)
Windows Anywhere	ms-settings:windowsanywhere (device must be Windows Anywhere-capable)
Windows Hello setup	ms-settings:signinoptions-launchfaceenrollment ms-settings:signinoptions-launchfingerprintenrollment
Your info	ms-settings:yourinfo

Apps

Expand table

Settings page	URI
Apps & Features	ms-settings:appsfeatures
App features	ms-settings:appsfeatures-app (Reset, manage add-on & downloadable content, etc. for the app) To access this page with a URI, use the ms-settings:appsfeatures-app URI and pass an optional parameter of the *package family name* of the app.

Settings page	URI
	Example: `ms-settings:appsfeatures-app?<PFN>`
Apps for websites	ms-settings:appsforwebsites
Default apps	ms-settings:defaultapps (**Behavior introduced in Windows 11, version 21H2 (with 2023-04 Cumulative Update) or 22H2 (with 2023-04 Cumulative Update), or later.**) Append the query string parameter in the following formats using the Uri-escaped name of an app to directly launch the default settings page for that app: - registeredAppMachine=<Uri-escaped per machine installed name of app> - registeredAppUser=<Uri-escaped per user installed name of app> - registeredAUMID=<Uri-escaped Application User Model ID> For more information, see Launch the Default Apps settings page.
Default browser settings	ms-settings:defaultbrowsersettings (**Deprecated in Windows 11**)
Manage optional features	ms-settings:optionalfeatures
Offline Maps	ms-settings:maps ms-settings:maps-downloadmaps (Download maps)
Startup apps	ms-settings:startupapps
Video playback	ms-settings:videoplayback

Control Center

Expand table

Settings page	URI
Control center	ms-settings:controlcenter

Cortana

Expand table

Settings page	URI
Cortana across my devices	ms-settings:cortana-notifications
More details	ms-settings:cortana-moredetails
Permissions & History	ms-settings:cortana-permissions
Searching Windows	ms-settings:cortana-windowssearch
Talk to Cortana	ms-settings:cortana-language ms-settings:cortana ms-settings:cortana-talktocortana

Important

Cortana voice assistance in Windows as a standalone app was retired in the spring of 2023. For more information, see End of support for Cortana.

Note

This Settings section on desktop will be called Search when the PC is set to regions where Cortana is not currently available or Cortana has been disabled. Cortana-specific pages (Cortana across my devices, and Talk to Cortana) will not be listed in this case.

Devices

Expand table

Settings page	URI
AutoPlay	ms-settings:autoplay
Bluetooth	ms-settings:bluetooth
Connected Devices	ms-settings:connecteddevices
Default camera	ms-settings:camera (**Behavior deprecated in Windows 10, version 1809 and later**)

Settings page	URI
Camera settings	ms-settings:camera (**Behavior introduced in Windows 11, build 22000 and later**) Append the query string parameter `cameraId` set to the Uri-escaped symbolic link name of a camera device to directly launch the settings for that camera. For more information, see Launch the camera settings page.
Mouse & touchpad	ms-settings:mousetouchpad (touchpad settings only available on devices that have a touchpad)
Pen & Windows Ink	ms-settings:pen
Printers & scanners	ms-settings:printers
Touch	ms-settings:devices-touch
Touchpad	ms-settings:devices-touchpad (only available if touchpad hardware is present)
Text Suggestions	ms-settings:devicestyping-hwkbtextsuggestions
Typing	ms-settings:typing
USB	ms-settings:usb
Wheel	ms-settings:wheel (only available if a **Surface Dial** device is paired)
Your phone	ms-settings:mobile-devices

Ease of access

Launching, resuming, and background tasks

Launch the Default Apps settings page

Article • 02/13/2025

Learn how to launch the Windows Settings app to display the Default Apps settings page from your app using the ms-settings URI scheme.

Windows defines a set of URIs that allow apps to launch the Windows Settings app and display a particular settings page. This article explains how to launch the Windows Settings app directly to the Default Apps settings page and, optionally, navigate directly to the settings for a specified default application. For more information, see Launch the Windows Settings app.

The Default Apps settings URL

`ms-settings:defaultapps` launches the Windows Settings app and navigates to the Default Apps settings page. Starting with Windows 11, version 21H2 (with 2023-04 Cumulative Update), 22H2 (with 2023-04 Cumulative Update), and 23H2 or later, you can append an additional query string parameter in escaped URI format to launch directly to the settings page for a specific application.

There are three query string parameters. The query string parameter to be used depends on how the application was installed.

Expand table

Query string parameter	Value to pass
registeredAppUser	Named value from HKEY_CURRENT_USER\Software\RegisteredApplications Use when the app was installed per user, and the registration for the app was written to HKEY_CURRENT_USER\Software\RegisteredApplications.
registeredAppMachine	Named value from HKEY_LOCAL_MACHINE\Software\RegisteredApplications Use when the app was installed per machine, and the registration for the app was written to HKEY_LOCAL_MACHINE\Software\RegisteredApplications.
registeredAUMID	Application User Model ID

Query string parameter	Value to pass
	Use when the app was registered with Package Manager using a manifest declaring that the app handles File Types (uap:FileTypeAssociation) or URI schemes (uap:Protocol).

> **Note**
>
> To get the registeredAUMID query string parameter to work after an OS upgrade, an app may need to increment its TargetDeviceFamily...MaxVersionTested value in its manifest. This will ensure that the app is reindexed for the user, which in turn will update the appropriate definitions used to process the deep link via protocol activation. MaxVersionTested should be updated to `10.0.22000.1817` for Windows 11, version 21H2 or `10.0.22621.1555` for Windows 11, version 22H2.

In the following example, `LaunchUriAsync` is called to launch the Windows Settings app. The `ms-settings:defaultapps` Uri specifies that the Default Apps settings page should be shown. Next, the app that should be launched is determined. As an example, "Microsoft Edge" was registered by the app in HKEY_LOCAL_MACHINE\Software\RegisteredApplications. Since it is a per machine installed app, `registeredAppMachine` is the query string parameter that should be used. The optional query string parameter `registeredAppMachine` is set to the registered name, escaped with a call to `Url.EscapeDataString`, to specify that the page for **Microsoft Edge** should be shown.

C#

```
private async void LaunchSettingsPage_Click(object sender, RoutedEventArgs
e)
{
    bool result = await Windows.System.Launcher.LaunchUriAsync(new Uri("ms-
settings:defaultapps?registeredAppMachine=" +
Uri.EscapeDataString("Microsoft Edge")));
}
```

Launch the default app for a URI

Using ms-windows-store URIs

Article • 02/19/2025

This topic describes the **ms-windows-store:** URI scheme. Your app can use this URI scheme to launch the Microsoft Store app to specific pages in the store by using the LaunchUriAsync method on Windows.

For example, you can open the Store to the Games page using the following code:

C#

```
bool result = await Windows.System.Launcher.LaunchUriAsync(new Uri("ms-windows-store://navigatetopage/?Id=Gaming"));
```

Opening the Store to specific sections

You can launch the Store App to a specific page or section using the following options:

Expand table

URI Scheme	Description	Notes
ms-windows-store://home	Launches the home page of the Store.	
ms-windows-store://navigatetopage/?Id=[vertical]	Launches a top-level vertical page of the store	Verticals include: `Home`, `Gaming`, `Entertainment`, `Productivity`, and `LOB`, but note that available verticals can vary by region.
ms-windows-store://downloadsandupdates	Launches the Updates and downloads page.	
ms-windows-store://mylibrary	Launches the Library page of the Store.	
ms-windows-store://settings	Launches the Store settings page.	

Opening to a specific product

You can launch the Store directly to the product detail page (PDP) for a specific product by using the Product ID for an App. While the Store app on Windows 10 and Windows 11 still supports Package Family Name (PFN) and App IDs, these are deprecated and may not be supported in the future. These values can be found in Partner Center on the App identity page in the Product management section for each app.

Starting with the October 2021 update to the Store app, there are two modes available for displaying the PDP. By default the Store app is opened to the product detail page. You can also launch the store into with a popup experience that displays a smaller PDP dialog with that only displays the essential details for your app and a single action button for users. For the popup experience, you can optionally specify the location of a window that the dialog should be centered above.

Expand table

URI Scheme	Description	Notes
ms-windows-store://pdp/?ProductId=9WZDNCRFHVJL	Launches the full product details page (PDP) for a product	This is the recommended way to link to a specific product.
ms-windows-store://pdp/?PFN=Microsoft.Office.OneNote_8wekyb3d8bbwe	Launches the full product details page (PDP) for a product	Using the package family name is deprecated.
ms-windows-store://pdp/?AppId=00001111-aaaa-2222-bbbb-3333cccc4444	Launches the full product details page (PDP) for a product	Using the App ID is deprecated.
ms-windows-store://pdp/?ProductId=9WZDNCRFHVJL&mode=mini	Launches the popup Store dialog experience	The popup experience only supports Product ID

Launching the rating and review experience for a product

To enable users to review your app, you can link to that PDP and launch directly into the rating and review dialog. Store ID is the recommended method to launch the Store app to a specific product detail page.

Expand table

URI Scheme	Description	Notes
ms-windows-store://review/?ProductId=9WZDNCRFHVJL	Launches the write a review experience for a product.	Using StoreId is recommended
ms-windows-store://review/?PFN=Microsoft.Office.OneNote_8wekyb3d8bbwe	Launches the write a review experience for a product.	Using product family name is deprecated.
ms-windows-store://review/?AppId=11112222-bbbb-3333-cccc-4444dddd5555	Launches the write a review experience for a product.	Using productid is deprecated

Searching the Store

You can launch the Store app directly into search results with several supported methods for searching store content.

Expand table

URI Scheme	Description	Notes
ms-windows-store://assoc/?Tags=Photos_Rich_Media_Edit,Camera_Capture_App	Launches a search for products associated with one or more tags.	Tags must be separated by commas.
ms-windows-store://search/?query=OneNote	Launches a search for the specified query.	Spaces in the query are allowed.
ms-windows-store://browse/?type=Apps&cat=Health+%26+fitness	Launches a search for products in a category.	
ms-windows-store://publisher/?name=Microsoft Corporation	Launches a search for products from the specified publisher.	Spaces in the name are allowed.
ms-windows-store://assoc/?FileExt=pdf	Launches a search for products associated with a file extension.	
ms-windows-store://assoc/?Protocol=ms-word	Launches a search for products associated with a protocol.

Launching, resuming, and background tasks

Launch the Windows Maps app

Article • 02/13/2025

Learn how to launch the Windows Maps app from your app. This topic describes the **bingmaps:**, **ms-drive-to:**, **ms-walk-to:**, and **ms-settings:** Uniform Resource Identifier (URI) schemes. Use these URI schemes to launch the Windows Maps app to specific maps, directions, and search results or to download Windows Maps offline maps from the Settings app.

> **Tip**
>
> To learn more about launching the Windows Maps app from a Universal Windows Platform (UWP) app, download the UWP map sample from the Windows-universal-samples repo on GitHub. You can use the same Windows Runtime (WinRT) APIs for launching URIs in WinUI and other desktop apps to launch the Windows Maps app.

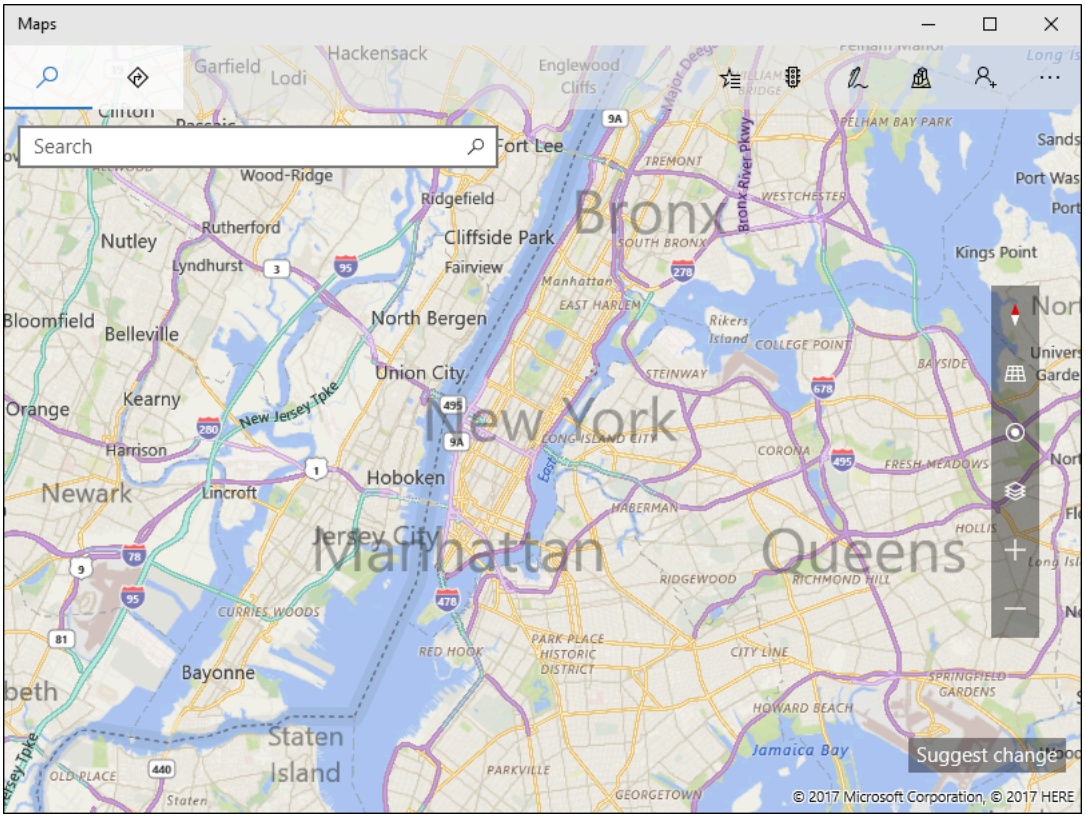
Introducing URIs

URI schemes let you open apps by clicking hyperlinks (or programmatically, in your app). Just as you can start a new email using **mailto:** or open a web browser using **http:**, you can open the Windows maps app using **bingmaps:**, **ms-drive-to:**, and **ms-walk-to:**.

- The **bingmaps:** URI provides maps for locations, search results, directions, and traffic.
- The **ms-drive-to:** URI provides turn-by-turn driving directions from your current location.
- The **ms-walk-to:** URI provides turn-by-turn walking directions from your current location.

For example, the following URI opens the Windows Maps app and displays a map centered over New York City:

```
bingmaps:?cp=40.726966~-74.006076
```



Here is a description of the URI scheme:

```
bingmaps:?query
```

In this URI scheme, *query* is a series of parameter name/value pairs:

```
&param1=value1&param2=value2 …
```

For a full list of the available parameters, see the bingmaps:, ms-drive-to:, and ms-walk-to: parameter reference. There are also examples later in this topic.

Launch a URI from your app

To launch the Windows Maps app from your app, call the LaunchUriAsync method with a **bingmaps:**, **ms-drive-to:**, or **ms-walk-to:** URI. The following example launches the same URI from the previous example. For more info about launching apps via URI, see Launch the default app for a URI.

```cs
// Center on New York City
var uriNewYork = new Uri(@"bingmaps:?cp=40.726966~-74.006076");

// Launch the Windows Maps app
var launcherOptions = new Windows.System.LauncherOptions();
launcherOptions.TargetApplicationPackageFamilyName = "Microsoft.WindowsMaps_8wekyb3d8bbwe";
var success = await Windows.System.Launcher.LaunchUriAsync(uriNewYork, launcherOptions);
```

In this example, the LauncherOptions class is used to help ensure the Windows Maps app is launched.

Display known locations

There are many options to control which part of the map to show. You can use the *cp* (center point) parameter with either the *rad* (radius) or the *lvl* (zoom level) parameters to show a location and choose how close to zoom in to it. When you use the *cp* parameter, you can also specify a *hdg* (heading) and *pit* (pitch) to control what direction to look. Another method is to use the *bb* (bounding box) parameter to provide the maximum south, east, north, and west coordinates of the area you want to show.

To control the type of view, use the *sty* (style) and *ss* (Streetside) parameters. The *sty* parameter lets you switch between road and aerial views. The *ss* parameter puts the map into a Streetside view. For more info about these and other parameters, see the bingmaps: parameter reference.

Expand table

Sample URI	Results
bingmaps:?	Opens the Maps app.
bingmaps:?cp=40.726966~-74.006076	Displays a map centered over New York City.
bingmaps:?cp=40.726966~-74.006076&lvl=10	Displays a map centered over New York City with a zoom level of 10.
bingmaps:?bb=39.719_-74.52~41.71_-73.5	Displays a map of New York City, which is the area specified in the **bb** argument.
bingmaps:?bb=39.719_-74.52~41.71_-73.5&cp=47~-122	Displays a map of New York City, which is the area specified in the bounding box argument. The center point for Seattle specified in the **cp** argument is ignored because *bb* is specified.
bingmaps:?collection=point.36.116584_-115.176753_Caesars%20Palace&lvl=16	Displays a map with a point named Caesars Palace (in Las Vegas) and sets the zoom level to 16.
bingmaps:?collection=point.40.726966_-74.006076_Some%255FBusiness	Displays a map with a point named Some_Business (in Las Vegas).
bingmaps:?cp=40.726966~-74.006076&trfc=1&sty=a	Displays a map of New York City with traffic on and aerial map style.
bingmaps:?cp=47.6204~-122.3491&sty=3d	Displays a 3D view of the Space Needle.
bingmaps:?cp=47.6204~-122.3491&sty=3d&rad=200&pit=75&hdg=165	Displays a 3D view of the Space Needle with a radius of 200m, a pitch of 75 degrees, and a heading of 165 degrees.
bingmaps:?cp=47.6204~-122.3491&ss=1	Displays a Streetside view of the Space Needle.

Display search results

When searching for places using the *q* parameter, we recommend making the terms as specific as possible and using the *cp*, *bb*, or *where* parameters to specify a search location. If you do not specify a search location and the user's current location isn't available, the search may not return meaningful results. Search results are displayed in the most appropriate map view. For more info about these and other parameters, see the bingmaps: parameter reference.

Expand table

Sample URI	Results
bingmaps:?q=1600%20Pennsylvania%20Ave,%20Washington,%20DC	Displays a map and searches for the address of the White House in Washington, D.C.
bingmaps:?q=coffee&where=Seattle	Searches for coffee in Seattle.
bingmaps:?cp=40.726966~-74.006076&where=New%20York	Searches for New York near the specified center point.
bingmaps:?bb=39.719_-74.52~41.71_-73.5&q=pizza	Searches for pizza in the specified bounding box (that is, in New York City).

Display multiple points

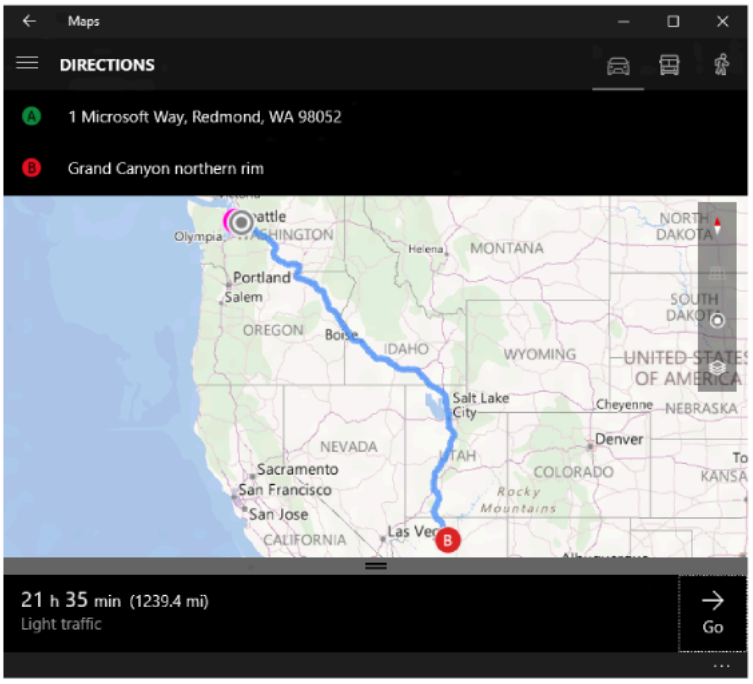
Use the *collection* parameter to show a custom set of points on the map. If there is more than one point, a list of points is displayed. There can be up to 25 points in a collection and they are listed in the order provided. The collection takes precedence over search and directions requests. For more info about this parameter and others, see the bingmaps: parameter reference.

Expand table

Sample URI
bingmaps:?collection=point.36.116584_-115.176753_Caesars%20Palace
bingmaps:?collection=point.36.116584_-115.176753_Caesars%20Palace&lvl=16
bingmaps:?collection=point.36.116584_-115.176753_Caesars%20Palace~point.36.113126_-115.175188_The%20Bellagio&lvl=16&cp=36.114902~-115.176669
bingmaps:?collection=point.40.726966_-74.006076_Fake%255FBusiness%255Fwith%255FUnderscore
bingmaps:? collection=name.Hotel%20List~point.36.116584_-115.176753_Caesars%20Palace~point.36.113126_-115.175188_The%20Bellagio&lvl=16&cp=36.114902~-115.176669

Display directions and traffic

You can display directions between two points using the *rtp* parameter; those points can be either addresses or latitude and longitude coordinates. Use the *trfc* parameter to show traffic information. To specify the type of directions: driving, walking, or transit, use the *mode* parameter. If *mode* isn't specified, directions will be provided using the user's preferred mode of transportation. For more info about these parameters and others, see the bingmaps: parameter reference.



Expand table

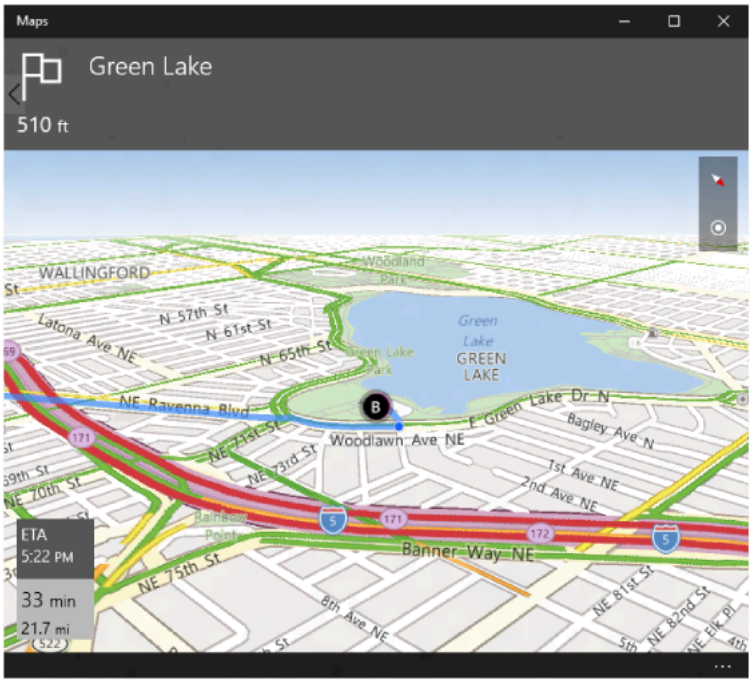
Sample URI	Results
bingmaps:?rtp=pos.44.9160_-110.4158~pos.45.0475_-109.4187	Displays a map with point-to-point directions. Because *mode* is not specified, directions will be provided using the user's mode of transportation preference.
bingmaps:?cp=43.0332~-87.9167&trfc=1	Displays a map centered over Milwaukee, WI with traffic.
bingmaps:?rtp=adr.One Microsoft Way, Redmond, WA 98052~pos.39.0731_-108.7238	Displays a map with directions from the specified address to the specified location.
bingmaps:? rtp=adr.1%20Microsoft%20Way,%20Redmond,%20WA,%2098052~pos.36.1223_-111.9495_Grand%20Canyon%20northern%20rim	Displays directions from 1 Microsoft Way, Redmond, WA, 98052 to the Grand Canyon's northern rim.
bingmaps:?rtp=adr.Davenport, CA~adr.Yosemite Village	Displays a map with driving directions from the specified location to the specified landmark.
bingmaps:?rtp=adr.Mountain%20View,%20CA~adr.San%20Francisco%20International%20Airport,%20CA&mode=d	Displays driving directions from Mountain View, CA to San Francisco International Airport, CA.
bingmaps:?rtp=adr.Mountain%20View,%20CA~adr.San%20Francisco%20International%20Airport,%20CA&mode=w	Displays walking directions from Mountain View, CA to San Francisco International Airport, CA.

Sample URI	Results
bingmaps:?rtp=adr.Mountain%20View,%20CA~adr.San%20Francisco%20International%20Airport,%20CA&mode=t	Displays transit directions from Mountain View, CA to San Francisco International Airport, CA.

Display turn-by-turn directions

The **ms-drive-to:** and **ms-walk-to:** URI schemes let you launch directly into a turn-by-turn view of a route. These URI schemes can only provide directions from the user's current location. If you must provide directions between points that do not include the user's current location, use the **bingmaps:** URI scheme as described in the previous section. For more info about these URI schemes, see the ms-drive-to: and ms-walk-to: parameter reference.

> **Important** When the **ms-drive-to:** or **ms-walk-to:** URI schemes are launched, the Maps app will check to see if the device has ever had a GPS location fix. If it has, then the Maps app will proceed to turn-by-turn directions. If it hasn't, the app will display the route overview, as described in Display directions and traffic.



Expand table

Sample URI	Results
ms-drive-to:? destination.latitude=47.680504&destination.longitude=-122.328262&destination.name=Green Lake	Displays a map with turn-by-turn driving directions to Green Lake from your current location.
ms-walk-to:? destination.latitude=47.680504&destination.longitude=-122.328262&destination.name=Green Lake	Displays a map with turn-by-turn walking directions to Green Lake from your current location.

Download offline maps

The **ms-settings:** URI scheme lets you launch directly into a particular page in the Settings app. While the **ms-settings:** URI scheme doesn't launch into the Maps app, it does allow you to launch directly to the Offline Maps page in the Settings app and displays a confirmation dialog to download the offline maps used by the Maps app. The URI scheme accepts a point specified by a latitude and longitude and automatically determines if there are offline maps available for a region containing that point. If the latitude and longitude passed happen to fall within multiple download regions, the confirmation dialog will let the user pick which of those regions to download. If offline maps are not available for a region containing that point, the offline Maps page in the Settings app is displayed with an error dialog.

Expand table

Sample URI	Results
ms-settings:maps-downloadmaps?latlong=47.6,-122.3	Opens the Settings app to the Offline Maps page with a confirmation dialog displayed to download maps for the region containing the specified latitude-longitude point.

bingmaps: parameter reference

The syntax for each parameter in this table is shown by using Augmented Backus–Naur Form (ABNF).

Expand table

Parameter	Definition	ABNF Definition and Example
cp	Center point	cp = "cp=" cpval cpval = degreeslat "~" degreeslon degreeslat = ["-"] 1*3DIGIT ["." 1*7DIGIT] degreeslon = ["-"] 1*2DIGIT ["." 1*7DIGIT] Example: cp=40.726966~-74.006076
bb	Bounding box	bb = "bb=" southlatitude "_" westlongitude "~" northlatitude "_" eastlongitude southlatitude = degreeslat northlatitude = degreeslat westlongitude = degreeslon eastlongitude = degreeslon degreeslat = ["-"] 13DIGIT ["." 17DIGIT] degreeslon = ["-"] 12DIGIT ["." 17DIGIT] Example: bb=39.719_-74.52~41.71_-73.5
where	Location	where = "where=" whereval whereval = 1*(ALPHA / DIGIT / "-" / "." / "_" / pct-encoded / "!" / "$" / "'" / "(" / ")" / "*" / "+" / "," / ";" / ":" / "@" / "/" / "?") Example: where=1600%20Pennsylvania%20Ave,%20Washington,%20DC

ms-drive-to: parameter reference

The URI to launch a request for turn-by-turn driving directions does not need to be encoded and has the following format.

> **Note**
>
> You don't specify the starting point in this URI scheme. The starting point is always assumed to be the current location. If you need to specify a starting point other than the current location, see Display directions and traffic.

Expand table

Parameter	Definition	Example	Details
destination.latitude	Destination latitude	Example: destination.latitude=47.6451413797194	The latitude of the destination. Valid latitude values are between -90 and +90 inclusive.
destination.longitude	Destination longitude	Example: destination.longitude=-122.141964733601	The longitude of the destination. Valid longitude values are between -180 and +180 inclusive.
destination.name	Name of the destination	Example: destination.name=Redmond, WA	The name of the destination. You do not have to encode the **destination.name** value.

ms-walk-to: parameter reference

The URI to launch a request for turn-by-turn walking directions does not need to be encoded and has the following format.

> **Note**
>
> You don't specify the starting point in this URI scheme. The starting point is always assumed to be the current location. If you need to specify a starting point other than the current location, see Display directions and traffic.

Expand table

Parameter	Definition	Example	Details
destination.latitude	Destination latitude	Example: destination.latitude=47.6451413797194	The latitude of the destination. Valid latitude values are between -90 and +90 inclusive.
destination.longitude	Destination longitude	Example: destination.longitude=-122.141964733601	The longitude of the destination. Valid longitude values are between -180 and +180 inclusive.
destination.name	Name of the destination	Example: destination.name=Redmond, WA	The name of the destination. You do not have to encode the **destination.name** value.

ms-settings: parameter reference

The syntax for maps app specific parameters for the **ms-settings:** URI scheme is defined below. **maps-downloadmaps** is specified along with the **ms-settings:** URI in the form of **ms-settings:maps-downloadmaps?** to indicate the offline maps settings page.

Expand table

Parameter	Definition	Example	Details
latlong	Point defining offline map region.	Example: latlong=47.6,-122.3	The geopoint is specified by a comma separated latitude and longitude. Valid latitude values are between -90 and +90 inclusive. Valid longitude values are between -180 and +180 inclusive.

Launch the default app for a URI

Launch Snipping Tool

Article • 02/25/2025

This article specifies the protocol for integrating first and third-party applications with the Windows Snipping Tool using the **ms-screenclip:** URI (Uniform Resource Identifier) scheme. The protocol facilitates the capture of images and video (with audio) via Snipping Tool. App callers can customize and choose which Snipping Tool features their app will display. The protocol is designed to offer flexibility, security, and ease of use, aligning closely with familiar HTTP-based interactions. This shift can make the protocol more intuitive for developers and facilitate its integration with web technologies.

> **Note**
>
> This protocol launch replaces the previous existing experience documented here.

Supported features

The Snipping Tool protocol supports the following features:

- Rectangle Capture
- Freeform Capture
- Window Capture
- Ability to launch directly into a Screenshot or Recording
- Customizing features available
- Autosave feature is available, but can be disabled

Protocol Specification

URI Scheme: `{scheme}://{host}/{path}?{query}`

ms-screenclip: takes the following parameters:

- **Scheme:** `ms-screenclip` - The custom scheme for Snipping Tool's protocol.
- **Host:** Defines the Snipping Tool operation to perform (`capture` for snipping and recording, `discover` for querying capabilities).
- **Path:** Specifies the media type to capture, such as an image (`/image`) or video (`/video`).
- **Query:** Parameters for the specified schema.

Host (required)

- Capture
- Discover

Path (required)

- Image
- Video

Query

Capture Host

Expand table

Parameter	Type	Required	Description	Default
`api-version`	string	no	Protocol version (e.g., `"1.0"`). Ensures compatibility with future enhancements.	Latest version
`user-agent`	string	yes	Identifier for the calling application, used for logging and analytics.	n/a
`x-request-correlation-id`	string	no	Unique identifier for requests, allowing reference to a particular transaction or event chain.	Generated GUID if not provided.
`host`	string (enum)	yes	Specifies the **Snipping Tool action** to perform. Supported values: - `capture` – Opens Snipping Tool to take a screenshot or recording. - `discover` – Queries supported features.	`capture`
`path`	string (enum)	yes	Specifies the **type of media** being captured: - `image` – Screenshot capture. - `video` – Screen recording.	n/a
`enabledModes`	string (list)	no	Controls which snipping or recording modes are **enabled** in the UI. - `RectangleSnip` - `WindowSnip`	Defaults to the mode specified in the URI (`path`)

Parameter	Type	Required	Description	Default
			- `FreeformSnip` - `FullscreenSnip` - `RectangleRecord` - `SnippingAllModes` (all image modes) - `RecordAllModes` (all recording modes) - `All` (all supported modes)	
`auto-save`	boolean	no	Determines whether the captured **Screenshot or Recording** is automatically saved to the user's device. If set to `false`, the file is stored temporarily and can only be accessed using the token provided in the response. **Note:** The screenshot or recording will only be automatically saved if the user has enabled the corresponding Snipping Tool settings: - **"Automatically save original screenshots"** for screenshots. - **"Automatically save original screen recordings"** for recordings.	`false`
`redirect-uri`	URI	yes	Callback URI where the response will be sent. The calling application must register a handler for this protocol to receive and process the response.	n/a

Discover Host

The Snipping Tool protocol supports a `discover` endpoint that allows applications to retrieve available features, supported modes, and protocol versions dynamically. This is useful for ensuring compatibility with future updates or querying what capture methods are available.

How to Use

To retrieve Snipping Tool's supported capabilities, use the following URI:

```
ms-screenclip://discover?redirect-uri=my-snip-protocol-test-app://response
```

Response Format

The response is a JSON object containing:

- Version number (version) of the protocol.
- List of available capture paths (path), including:
  - capture/image (for snipping)
  - capture/video (for recording)
- Supported HTTP-like methods (methods).
- Available parameters (parameters) that can be used in requests.
- Description of each capability.

Example Response

JSON

```
{
  "version": 1.2,
  "capabilities": [
    {
      "path": "capture/image",
      "methods": ["GET"],
      "parameters": ["rectangle", "freeform", "window"],
      "description": "Captures an image with options for shape."
    },
    {
      "path": "capture/video",
      "methods": ["GET"],
      "parameters": [],
      "description": "Captures a video in a defined area."
    }
  ]
}
```

EnabledModes

The **enabledModes** parameter is designed to give developers granular control over the available UI options when invoking the ms-screenclip protocol. This allows for a tailored user experience that matches the specific requirements of the calling application. By specifying the **enabledModes** parameter, developers can restrict the user's choices in Snipping Tool's UI to ensure the output format meets their expectations.

Supported modes

The **enabledModes** parameter can accept the following modes:

- **RectangleSnip:** Enables rectangle capture mode.
- **WindowSnip:** Enables window capture mode.

- **FreeformSnip:** Enables freeform capture mode.
- **FullscreenSnip:** Enables fullscreen capture mode.
- **SnippingAllModes:** Enables all snipping (image capture) modes (RectangleSnip, WindowSnip, FreeformSnip, FullscreenSnip).
- **RectangleRecord:** Enables rectangle recording mode.
- **RecordAllModes:** Enables all recording modes (currently only RectangleRecord is available).
- **All:** Enables all supported modes (RectangleSnip, WindowSnip, FreeformSnip, FullscreenSnip, RectangleRecord).

> ⓘ **Important**
>
> If the **enabledModes** parameter is omitted, Snipping Tool will default to the mode explicitly specified in the URI (e.g., `rectangle`, `freeform`).
>
> - If a mode is explicitly specified in the URI (such as `rectangle`), only that mode will be available in Snipping Tool's UI.
> - If no default mode is specified in the URI, the request is considered invalid and will be ignored, even if **enabledModes** is provided.
> - The default mode parameter (e.g., `rectangle`, `freeform`) is required for **enabledModes** to function and for the request to be considered valid.

Examples

Example 1: Enable Only Rectangle Snip

`ms-screenclip://capture/image?rectangle&enabledModes=RectangleSnip&redirect-uri=my-snip-protocol-test-app://response`

Explanation: This command launches Snipping Tool's overlay with only the rectangle snipping mode enabled. The user will only be able to select a rectangular region for capture.

Example 2: Enable Rectangle Snip and Window Snip

`ms-screenclip://capture/image?rectangle&enabledModes=RectangleSnip,WindowSnip&redirect-uri=my-snip-protocol-test-app://response`

Explanation: This command launches Snipping Tool's overlay with both the rectangle and window snipping modes enabled. The user can choose between capturing a rectangular region or an entire window.

Example 3: Enable All Snipping Modes

`ms-screenclip://capture/image?rectangle&enabledModes=SnippingAllModes&redirect-uri=my-snip-protocol-test-app://response`

Explanation: This command launches Snipping Tool's overlay with all supported image snipping modes (RectangleSnip, WindowSnip, FreeformSnip, FullscreenSnip). The FullScreenSnip mode is excluded from interactive mode and will not be enabled.

Example 4: Enable Recording Mode Only

`ms-screenclip://capture/video?enabledModes=RecordAllModes&redirect-uri=my-snip-protocol-test-app://response`

Explanation: This command launches Snipping Tool's overlay with only the recording mode enabled. The user will be limited to selecting a rectangular region for recording, with no option to take a screenshot.

Example 5: Enable Multiple Snipping and Recording Modes

`ms-screenclip://capture/image?freeform&enabledModes=RectangleSnip,RectangleRecord&redirect-uri=my-snip-protocol-test-app://response`

Explanation: This command launches the Snipping Tool overlay with freeform snip, rectangle snip, and rectangle recording modes available. Since freeform mode is specified in the URI, it will be pre-selected by default. Users can choose to snip in freeform, rectangle, or record the selected region.

Example 6: Enable Rectangle Snipping Only

`ms-screenclip://capture/image?rectangle&redirect-uri=my-snip-protocol-test-app://response`

Explanation: Since rectangle is specified in the URI, only rectangle snipping mode will be available in Snipping Tool's UI.

Example 7: No `mode` specified

`ms-screenclip://capture/image?&enabledModes=All&redirect-uri=my-snip-protocol-test-app://response`

Explanation: This request is invalid because it does not specify a mode (e.g., `rectangle`, `window`, or `freeform`). Even though `enabledModes=All` is provided, a default mode must always be specified. As a result, Snipping Tool will ignore the call.

Key considerations

- **Mode Restrictions:** Developers should ensure that enabling specific modes aligns with the expected behavior of their application. Restricting UI options helps maintain a consistent user experience and ensures the resulting capture matches the application's needs.
- **Default Behavior:** If no `enabledModes` parameter is specified, only the `mode` specified in the URI will be available on the UI.

Security Considerations

Important: Snipping Tool does not validate the redirect-uri parameter. It is the responsibility of the calling application to ensure that:

- The `redirect-uri` points to a trusted destination.
- The `redirect-uri` does not expose the captured content to unauthorized applications.
- The application handling the response sanitizes and validates all incoming parameters before processing them.
- The protocol handler for the `redirect-uri` is properly registered and secured against misuse.
- **Required Fields:** Check that all required fields are provided and valid before proceeding with the snip operation.

Response if expected parameters **aren't** supplied or overloaded.

Responses to the caller

To ensure the response back to the caller via `redirect-uri` follows HTTP-based interaction principles, the response will mimic the structure of an HTTP response, but

will be conveyed through URI query parameters. This approach keeps the interaction web-standard compliant and familiar to developers.

Use of shared tokens

The use of the `SharedStorageAccessManager` class and of sharing tokens is subject to the following requirements and restrictions:

- A sharing token can only be redeemed once. After that, the token is no longer valid.
- A sharing token expires after 14 days and is no longer valid.
- The source app cannot provide more than 1000 sharing tokens. After a token is redeemed, removed, or expires, however, it no longer counts against the quota of the source app.

Response parameters

The following parameters are returned in the redirect URI:

Expand table

Parameter	Type	Description
Reason	String	The outcome and explanation for the snip.
Token (for success)	String	A token representing the captured media, which the application can use to access the file.
code	Int	The HTTP status code equivalent to provide a more granular understanding of the outcome.
x-request-correlation-id	String	A unique identifier value attached to requests and messages that allows reference to a particular transaction or event chain.

Retrieving a token

A sample application is available to test the process of calling the protocol and converting the response token into media. Use the SharedStorageAccessManager library to obtain the token.

Status codes

The following table lists the status codes that can be returned in the redirect URI:

Expand table

HTTP Status Code	Reason	Description
200	Success	The operation was successful.
400	Bad Request - Invalid or Missing Parameters	The request cannot be processed due to client error.
408	Request Timeout - Operation Took Too Long	The operation timed out before completion.
499	Client Closed Request - User Cancelled the Snip	The user cancelled the snip, closing the request.
500	Internal Server Error - Processing Failed	An error occurred on the server, preventing completion.

Example responses

Expand table

Use Case	Full URI Example
Successful Capture	`my-snip-protocol-test-app://response/?code=200&reason=Success&request-correlation-id=CF99C5A5-3907-461E-A9A9-D8AAFFAD5031&token=8930-ASDFA-ASDF4545`
Failed Capture	`my-snip-protocol-test-app://response/?code=400&reason=Bad%20Request%20-%20Invalid%20value%20Missing%20Parameters&request-correlation-id=C7696B38-52C8-419A-880F-F3350D7A6626`

Caller example

Below is a table displaying examples of full URIs constructed to initiate different types of snipping sessions using the screenclip: protocol. Each URI example demonstrates a combination of parameters to illustrate how you can customize Snipping Tool's behavior for different use cases.

Expand table

Use Case	Example URI	Description
Rectangle Mode	`ms-screenclip://capture/image?user-agent=TestApp&Rectangle&uri=my-snip-protocol-`	An application initiates an interactive rectangle capture

Use Case	Example URI	Description
	`test-app://response`	session, where the user selects the capture area. The result is redirected to a specific URI.
Video Mode	`ms-screenclip://capture/video?api-version=1.0&user-agent=TestApp&redirect-uri=my-snip-protocol-test-app://response`	A video capture. Always in rectangle mode.

- Use Snipping Tool to capture screenshots
- Launch screen snipping (Legacy)

Launch screen snipping (Legacy)

Article • 02/25/2025

**This is a legacy method for activating the Snipping Tool. It will be deprecated on 05/01/2025. Please refer to the updated documentation: Launch Snipping Tool.

The **ms-screenclip:** and **ms-screensketch:** URI schemes allows you to initiate snipping or editing screenshots.

Open a new snip from your app

The **ms-screenclip:** URI allows your app to automatically open up and start a new snip. The resulting snip is copied to the user's clipboard, but is not automatically passed back to the opening app.

ms-screenclip: takes the following parameters:

Expand table

Parameter	Type	Required	Description
source	string	no	A freeform string to indicate the source that launched the URI.
type	string	no	A string value to indicate which special type of capture is requested. This parameter can be omitted when starting a new snip. Values supported include: snapshot, recording*
clippingMode	string	no	A string value to indicate the clipping type for the snip. Values supported include: Rectangle, Freeform, Window
delayInSeconds	int	no	An integer value, from 1 to 30. Specifies the delay, in full seconds, between the URI call and when snipping begins.
callbackformat	string	no	This parameter is unavailable.

* `type=recording` is available only on Windows 11 PCs with Snipping Tool version 11.2307 or newer, and only when the default handler for ms-screenclip is set to "Snipping Tool" instead of "Screen Clipping".

Launching the Snipping Tool or Snip & Sketch App

The **ms-screensketch:** URI allows you to programmatically launch the Snipping Tool app (on Windows 11) or Snip & Sketch app (on Windows 10), and open a specific image in that app for annotation.

ms-screensketch: takes the following parameters:

Expand table

Parameter	Type	Required	Description
sharedAccessToken	string	no	A token identifying the file to open. Retrieved from SharedStorageAccessManager.AddFile. If this parameter is omitted, the app will be launched without a file open.
secondarySharedAccessToken	string	no	A string identifying a JSON file with metadata about the snip. The metadata may include a **clipPoints** field with an array of x,y coordinates, and/or a userActivity.
source	string	no	A freeform string to indicate the source that launched the URI.
isTemporary	bool	no	If set to True, Snipping Tool will try to delete the file after opening it.

The following example calls the LaunchUriAsync method to send an image to Snipping Tool from the user's app.

C#

```
bool result = await Windows.System.Launcher.LaunchUriAsync(new Uri("ms-screensketch:edit?source=MyApp&isTemporary=false&sharedAccessToken=2C37ADDA-B054-40B5-8B38-11CED1E1A2D"));
```

The following example illustrates what a file specified by the **secondarySharedAccessToken** parameter of **ms-screensketch** might contain:

JSON

```
{
  "clipPoints": [
    {
      "x": 0,
      "y": 0
    },
    {
```

```
      "x": 2080,
      "y": 0
    },
    {
      "x": 2080,
      "y": 780
    },
    {
      "x": 0,
      "y": 780
    }
  ],

Launch a Windows app with a URI

Launch the People app

Article • 02/13/2025

This topic describes the **ms-people:** URI scheme. Your WinUI, UWP, and other Windows desktop apps can use this URI scheme to launch the People app for specific actions.

ms-people: URI scheme reference

Expand table

Results	URI scheme
Allows other apps to launch the People app Main page.	ms-people:
Allows other apps to launch the People app Settings page.	ms-people:settings
Allows other apps to provide a search string that will launch the People app with the result page of the search. The parameters are case sensitive. If you do not enter the syntax correctly, or are missing the search string value, the default behavior is to return a full list of contacts without any filtering.	ms-people:search?SearchString= <contactsearchinfo>
Launches to an existing contact card, if the contact is found. Or, launches to a temporary contact card, if no contact is found. If no input parameter is supplied, we will launch the People App with a contact list. The parameters are case sensitive. The order of the parameters doesn't matter. If there is more than one match, we will return the first match of the	ms-people:viewcontact?ContactId= <contactid>&AggregatedId= <aggid>&PhoneNumber= <phonenum>&Email= <email>&ContactName=<name>&Contact= <contactobj>

Results	URI scheme
contact.	
Launches to a Save-contact page within the People app to save the given contact with the supplied phone number or email address. The parameters are case sensitive. The order of the parameters doesn't matter.	ms-people:savetocontact?PhoneNumber=<phonenum>&Email=<email>&ContactName=<name>
Launches to the add a new contact page within the People app to save the given contact. Use **LaunchUriForResultsAsync** to open the save new contact page. Using **LaunchUriAsync** will only launch the People app Main page. The parameters are case sensitive. The order of the parameters doesn't matter. You can use any combination of supported parameters.	ms-people:savecontacttask?PhoneNumber=<phonenum>&Email=<email>&ContactName=<name>

Launch a Windows app with a URI

Launch the default app for a URI

Enable apps for websites using app URI handlers

Article • 02/13/2025

Apps for Websites associates your app with a website so that when someone opens a link to your website, your app is launched instead of opening the browser. If your app is not installed, your website opens in the browser as usual. Users can trust this experience because only verified content owners can register for a link. Users will be able to check all of their registered web-to-app links by going to Settings > Apps > Apps for websites.

> **ⓘ Important**
>
> Starting with the Windows 10 Creators update and in all Windows 11 versions, supported links clicked in Microsoft Edge Legacy will launch the corresponding app. Supported links clicked in supported browsers (for example, Microsoft Edge Chromium, Firefox, Internet Explorer, etc.), will keep you in the browsing experience.

To enable web-to-app linking you will need to:

- Identify the URIs your app will handle in the manifest file
- A JSON file that defines the association between your app and your website. with the app Package Family Name at the same host root as the app manifest declaration.
- Handle the activation in the app.

Register to handle http and https links in the app manifest

Your app needs to identify the URIs for the websites it will handle. To do so, add the **Windows.appUriHandler** extension registration to your app's manifest file **Package.appxmanifest**.

For example, if your website's address is "msn.com" you would make the following entry in your app's manifest:

XML

```
<Applications>
  <Application ... >
```

```
      ...
      <Extensions>
         <uap3:Extension Category="windows.appUriHandler">
          <uap3:AppUriHandler>
            <uap3:Host Name="msn.com" />
          </uap3:AppUriHandler>
        </uap3:Extension>
      </Extensions>
  </Application>
</Applications>
```

The declaration above registers your app to handle links from the specified host. If your website has multiple addresses (for example: m.example.com, www.example.com, and example.com) then add a separate `<uap3:Host Name=... />` entry inside of the `<uap3:AppUriHandler>` for each address.

Associate your app and website with a JSON file

To ensure that only your app can open content on your website, include your app's package family name in a JSON file located in the web server root, or at the well-known directory on the domain. This signifies that your website gives consent for the listed apps to open content on your site. You can find the package family name in the Packages section in the app manifest designer.

> **ⓘ Important**
>
> The JSON file should not have a .json file suffix.

Create a JSON file (without the .json file extension) named **windows-app-web-link** and provide your app's package family name. For example:

JSON

```
[{
  "packageFamilyName" : "Your app's package family name, e.g
MyApp_9jmtgj1pbbz6e",
  "paths" : [ "*" ],
  "excludePaths" : [ "/news/*", "/blog/*" ]
 }]
```

Windows will make an https connection to your website and will look for the corresponding JSON file on your web server.

Wildcards

The JSON file example above demonstrates the use of wildcards. Wildcards allow you to support a wide variety of links with fewer lines of code. Web-to-app linking supports two types of wildcards in the JSON file:

Expand table

Wildcard	Description
*	Represents any substring
?	Represents a single character

For example, given `"excludePaths" : [ "/news/*", "/blog/*" ]` in the example above, your app will support all paths that start with your website's address (for example, msn.com), **except** those under `/news/` and `/blog/`. **msn.com/weather.html** will be supported, but not **msn.com/news/topnews.html**.

Multiple apps

If you have two apps that you would like to link to your website, list both of the application package family names in your **windows-app-web-link** JSON file. Both apps can be supported. The user will be presented with a choice of which is the default link if both are installed. If they want to change the default link later, they can change it in **Settings** > **Apps for Websites**. Developers can also change the JSON file at any time and see the change as early as the same day but no later than eight days after the update.

JSON

```
[{
  "packageFamilyName": "Your apps's package family name, e.g
MyApp_9jmtgj1pbbz6e",
  "paths": [ "*" ],
  "excludePaths" : [ "/news/*", "/blog/*" ]
 },
 {
  "packageFamilyName": "Your second app's package family name, for example,
MyApp2_8jmtgj2pbbz6e",
  "paths": [ "/example/*", "/links/*" ]
 }]
```

To provide the best experience for your users, use exclude paths to make sure that online-only content is excluded from the supported paths in your JSON file.

Exclude paths are checked first and if there is a match the corresponding page will be opened with the browser instead of the designated app. In the example above, '/news/*' includes any pages under that path while '/news*' (no forward slash trails 'news') includes any paths under 'news*' such as 'newslocal/', 'newsinternational/', and so on.

Handle links on Activation to link to content

Navigate to **App.xaml.cs** in your app's Visual Studio solution and in **OnActivated()** add handling for linked content. In the following example, the page that is opened in the app depends on the URI path:

CS

```
protected override void OnActivated(IActivatedEventArgs e)
{
    Frame rootFrame = Window.Current.Content as Frame;
    if (rootFrame == null)
    {
        ...
    }

    // Check ActivationKind, Parse URI, and Navigate user to content
    Type deepLinkPageType = typeof(MainPage);
    if (e.Kind == ActivationKind.Protocol)
    {
        var protocolArgs = (ProtocolActivatedEventArgs)e;
        switch (protocolArgs.Uri.AbsolutePath)
        {
            case "/":
                break;
            case "/index.html":
                break;
            case "/sports.html":
                deepLinkPageType = typeof(SportsPage);
                break;
            case "/technology.html":
                deepLinkPageType = typeof(TechnologyPage);
                break;
            case "/business.html":
                deepLinkPageType = typeof(BusinessPage);
                break;
            case "/science.html":
                deepLinkPageType = typeof(SciencePage);
                break;
        }
    }

    if (rootFrame.Content == null)
    {
        // Default navigation
```

```
            rootFrame.Navigate(deepLinkPageType, e);
        }

        // Ensure the current window is active
        Window.Current.Activate();
    }
```

> **ⓘ Important**
>
> Make sure to replace the final `if (rootFrame.Content == null)` logic with `rootFrame.Navigate(deepLinkPageType, e);` as shown in the example above.

Test in a local validation tool

You can test the configuration of your app and website by running the App host registration verifier tool which is available in:

%windir%\system32**AppHostRegistrationVerifier.exe**

Test the configuration of your app and website by running this tool with the following parameters:

AppHostRegistrationVerifier.exe *hostname packagefamilyname filepath*

- Hostname: Your website (for example, microsoft.com)
- Package Family Name (PFN): Your app's PFN
- File path: The JSON file for local validation (for example, C:\SomeFolder\windows-app-web-link)

If the tool does not return anything, validation will work on that file when uploaded. If there is an error code, it will not work.

You can enable the following registry key to force path matching for side-loaded apps as part of local validation:

`HKCU\Software\Classes\LocalSettings\Software\Microsoft\Windows\CurrentVersion\AppModel\SystemAppData\YourApp\AppUriHandlers`

Keyname: `ForceValidation` Value: `1`

Test it: Web validation

Close your application to verify that the app is activated when you click a link. Then, copy the address of one of the supported paths in your website. For example, if your website's address is "msn.com", and one of the support paths is "path1", you would use `http://msn.com/path1`

Verify that your app is closed. Press **Windows Key + R** to open the **Run** dialog box and paste the link in the window. Your app should launch instead of the web browser.

Additionally, you can test your app by launching it from another app using the LaunchUriAsync API. You can use this API to test on phones as well.

If you would like to follow the protocol activation logic, set a breakpoint in the **OnActivated** event handler.

AppUriHandlers tips

These tips will help you get the most out of the AppUriHandlers feature:

- Make sure to only specify links that your app can handle.
- List all of the hosts that you will support. Note that www.example.com and example.com are different hosts.
- Users can choose which app they prefer to handle websites in Settings.
- Your JSON file must be uploaded to an https server.
- If you need to change the paths that you wish to support, you can republish your JSON file without republishing your app. Users will see the changes in 1-8 days.
- All sideloaded apps with AppUriHandlers will have validated links for the host on install. You do not need to have a JSON file uploaded to test the feature.
- This feature works whenever your app is a UWP app launched with LaunchUriAsync or a Windows desktop app launched with ShellExecuteEx. If the URL corresponds to a registered App URI handler, the app will be launched instead of the browser.

Handle URI Activation

Reserved file and URI scheme names in Windows

Article • 02/13/2025

You can use URI associations to automatically launch your app when another app launches a specific URI scheme. But there are some URI associations that you can't use because they are reserved. If your app registers for a reserved association, that registration will be ignored. This topic lists the reserved file and URI scheme names that are not available to your app.

Reserved file types

There are two types of reserved file types: file types reserved for built-in apps and file types reserved for the operating system. When a file type reserved for a built-in app is launched, only the built-in app will launch. Any attempt to register your app with that file type is ignored. Similarly, any attempt to register your app with a file type reserved for the operating system also will be ignored.

File types reserved for built-in apps:

Working with background tasks in Windows apps

Article • 02/13/2025

Learn how to create and register a background task in your app with the Windows Runtime (WinRT) BackgroundTaskBuilder class.

Register a background task

See the BackgroundTask sample for a complete example of registering a background task in a Universal Windows Platform (UWP) app.

The following example shows the registration of a Win32 COM task that runs on a recurring 15 minute timer.

To register a background task, you must first create a new instance of the BackgroundTaskBuilder class. The `BackgroundTaskBuilder` class is used to create and register background tasks in your app. The following code example demonstrates how to create a new instance of the `BackgroundTaskBuilder` class:

C#

```
using System;
using Windows.ApplicationModel.Background;

public IBackgroundTaskRegistration
RegisterBackgroundTaskWithSystem(IBackgroundTrigger trigger, Guid
entryPointClsid, string taskName)
{
    BackgroundTaskBuilder builder = new BackgroundTaskBuilder();

    builder.SetTrigger(trigger);
    builder.SetTaskEntryPointClsid(entryPointClsid);

    BackgroundTaskRegistration registration;
    if (builder.Validate())
    {
        registration = builder.Register(taskName);
    }
    else
    {
        registration = null;
    }

    return registration;
}
```

```
RegisterBackgroundTaskWithSystem(new TimeTrigger(15, false),
typeof(TimeTriggeredTask).GUID, typeof(TimeTriggeredTask).Name);
```

The `RegisterBackgroundTaskWithSystem` method takes three parameters:

- `trigger`: The trigger that will start the background task.
- `entryPointClsid`: The class ID of the background task entry point.
- `taskName`: The name of the background task.

The `RegisterBackgroundTaskWithSystem` method creates a new instance of the `BackgroundTaskBuilder` class and sets the trigger and entry point class ID for the background task. The method then registers the background task with the system.

> ⓘ **Note**
>
> This class is not agile, which means that you need to consider its threading model and marshaling behavior. For more info, see Threading and Marshaling (C++/CX) and Using Windows Runtime objects in a multithreaded environment (.NET).

Handle modern standby in a background task

The **BackgroundTaskBuilder** and related APIs already allow packaged desktop applications to run background tasks. The API now extends these APIs to enable these appls to execute code in modern standby. The update also adds properties that can be queried by an app to determine if the system will throttle background tasks for the application in modern standby to conserve battery life. This enables scenarios like apps receiving VoIP calls or other push notifications from modern standby.

> ⓘ **Note**
>
> "Packaged desktop applications" in this section refers to Win32 applications that have package identity (i.e., are Desktop Bridge or Sparse Signed Packaged applications) and have a main (or wmain) function as their entry point.

The following example shows how an app developer can use the **BackgroundTaskBuilder** API to register at most one task with the specified task name. The sample also shows how to check and opt in the task registration to run in modern standby for the application's most critical tasks.

```
```

C#

```
// The following namespace is required for BackgroundTaskBuilder APIs.
using Windows.ApplicationModel.Background;

// The following namespace is required for API version checks.
using Windows.Foundation.Metadata;

// The following namespace is used for showing Toast Notifications. This
// namespace requires the Microsoft.Toolkit.Uwp.Notifications NuGet package
// version 7.0 or greater.
using Microsoft.Toolkit.Uwp.Notifications;

// Incoming calls are considered to be critical tasks to the operation of
the app.
const string IncomingCallTaskName = "IncomingCallTask";
const string NotificationTaskName = "NotificationTask";
const string PrefetchTaskName = "PrefetchTask";

public static bool IsAllowedInBackground(BackgroundAccessStatus status) {
    return ((status != BackgroundAccessStatus.Denied) &&
            (status != BackgroundAccessStatus.DeniedBySystemPolicy) &&
            (status != BackgroundAccessStatus.DeniedByUser) &&
            (status != BackgroundAccessStatus.Unspecified));
}

public async void RegisterTask(IBackgroundTrigger trigger,
                               Guid entryPointClsid,
                               string taskName,
                               bool isRunInStandbyRequested)
{
    var taskBuilder = new BackgroundTaskBuilder();
    taskBuilder.SetTrigger(trigger);
    taskBuilder.SetTaskEntryPointClsid(entryPointClsid);

    // Only the most critical background work should be allowed to proceed
in
    // modern standby. Additionally, some platforms may not support modern
    // or running background tasks in modern standby at all. Only attempt to
    // request modern standby execution if both are true. Requesting network
    // is necessary when running in modern standby to handle push
notifications.
    if (IsRunInStandbyRequested &&
taskBuilder.IsRunningTaskInStandbySupported)
    {
        var accessStatus =
BackgroundExecutionManager.GetAccessStatusForModernStandby();
        if (!IsAllowedInBackground(accessStatus)
        {
            await
BackgroundExecutionManager.RequestAccessKindForModernStandby(

BackgroundAccessRequestKind.AllowedSubjectToSystemPolicy,
                    "This app wants to receive incoming notifications while
```

```
your device is asleep");
        }

        accessStatus =
BackgroundExecutionManager.GetAccessStatusForModernStandby();

        if (IsAllowedInBackground(accessStatus)
        {
            taskBuilder.IsRunningTaskInStandbyRequested = true;
            taskBuilder.IsNetworkRequested = true;
        }
    }

    // Check that the registration is valid before attempting to register.
    if (taskBuilder.IsRegistrationValid)
    {
        // If a task with the specified name already exists, it is
unregistered
        // before a new one is registered. Note this API may still fail from
        // catastrophic failure (e.g., memory allocation failure).
        taskBuilder.Register(taskName);
    }

    return;
}

RegisterTask(new PushNotificationTrigger(), "{INSERT-YOUR-GUID-HERE}",
IncomingCallTaskName, true);
```

Check if background tasks have exceeded their budget in modern standby

The following sample code shows how an app developer may use the **BackgroundWorkCost.WasApplicationThrottledInStandby** and **BackgroundWorkCost.ApplicationEnergyUseLevel** to monitor and react to having their background tasks exhaust its app budget. The app developer may react by reducing lower priority work being done in modern standby. Note this relies on the code from the previous sample.

C#

```
public async void ReduceBackgroundCost()
{
    BackgroundTaskRegistration callTask;
    BackgroundTaskRegistration notificationTask;
    BackgroundTaskRegistration prefetchTask;

    // Nothing to do if the app was not or will not be throttled.
    if (!BackgroundWorkCost.WasApplicationThrottledInStandby &&
```

```
        (BackgroundWorkCost.ApplicationEnergyUseLevel !=
StandbyEnergyUseLevel.OverBudget))
    {
        return;
    }

    foreach (var task in BackgroundTaskRegistration.AllTasks)
    {
        switch (task.Value.Name) {
        case IncomingCallTaskName:
            callTask = task.Value;
            break;

        case NotificationTaskName:
            notificationTask = task.Value;
            break;

        case PrefetchTaskName:
            prefetchTask = task.Value;
            break;

        default:
        }
    }

    if (callTask.WasTaskThrottledInStandby)
    {
        // Unset the throttle flag after acknowledging it so the app can
        // react to the same task being throttled again in the future.
        task.Value.WasTaskThrottledInStandby = false;

        // Notify the user that the notification was missed.
        new ToastContentBuilder()
            .AddText("You missed a call")
            .AddText(task.Value.Name)
            .Show();

        // Because the incoming calls were not activated, demote less
notifications
        // tasks so the calls can be delivered promptly in the future.
        RegisterTask(notificationTask.Value.Trigger,
                     typeof(TimeTriggeredTask).GUID,
                     notificationTask.Value.Name,
                     false);
    }

    // Note that if incoming call tasks were throttled in some previous
modern
    // standby session, the application energy use was over budget for some
period.
    // Demote unimportant tasks like prefetch work to avoid calls and
notifications
    // from being throttled.
    if (callTask.WasTaskThrottledInStandby) ||
        (BackgroundWorkCost.ApplicationEnergyUseLevel ==
```

```
StandbyEnergyUseLevel.OverBudget))
    {
        RegisterTask(prefetchTask.Value.Trigger,
                     typeof(TimeTriggeredTask).GUID,
                     prefetchTask.Value.Name,
                     false);
    }

    return;
}
```

Monitor background task energy use trends

The following is an incremental end to end update to the following C++WinRT/C# sample code on GitHub.

The example shows how you can use the **BackgroundWorkCost.ApplicationEnergyUseTrend** to monitor how your background tasks trend towards exhausting their budget. You can also stop the most expensive background tasks from running in modern standby and prevent background tasks from running in modern standby if their app is using its budget too quickly. This sample relies on code from previous samples.

C#

```
public async void ReduceBackgroundCostPreemptively()
{
    BackgroundTaskRegistration mostExpensiveTask = null;

    // We can't do anything preemptively since the trend isn't known.
    if (!BackgroundWorkCost.IsApplicationEnergyUseTrendKnown)
    {
        return;
    }

    // The app is not trending towards being over budget, so this method can
    // return early.
    if ((BackgroundWorkCost.ApplicationEnergyUseTrend !=
EnergyUseTrend.OverBudget) &&
        (BackgroundWorkCost.ApplicationEnergyUseTrend !=
EnergyUseTrend.OverHalf))
    {
        return;
    }

    // The application is going exceeding its budget very quickly. Demote
the
    // most expensive task that is not the call task before call tasks start
being
```

```
    // throttled.
    if (BackgroundWorkCost.ApplicationEnergyUseTrend ==
EnergyUseTrend.OverBudget)
    {
        foreach (var task in BackgroundTaskRegistration.AllTasks)
        {
            if ((task.Value.Name != IncomingCallTaskName) &&
                ((mostExpensiveTask == null) ||

 (mostExpensiveTask.ApplicationEnergyUseTrendContributionPercentage <

task.Value.ApplicationEnergyUseTrendContributionPercentage)))
            {
                mostExpensiveTask = task.Value;
            }
        }
    }

    if (mostExpensiveTask != null)
    {
        RegisterTask(mostExpensiveTask.Trigger,
                     typeof(TimeTriggeredTask).GUID,
                     mostExpensiveTask.Name,
                     false);
    }

    // The application is trending toward eventually exceeding its budget.
Demote the
    // least important prefetch task before calls and notifications are
throttled.
    foreach (var task in BackgroundTaskRegistration.AllTasks)
    {
        if (task.Value.Name == PrefetchTaskName) {
            RegisterTask(task.Value.Trigger,
                         typeof(TimeTriggeredTask).GUID,
                         task.Value.Name,
                         false);
        }
    }

    return;
}
```

Background tasks and network connectivity

If your background task requires network connectivity, be aware of the following considerations.

Network related triggers

- Use a SocketActivityTrigger to activate the background task when a packet is received and you need to perform a short-lived task. After performing the task, the background task should terminate to save power.
- Use a ControlChannelTrigger to activate the background task when a packet is received and you need to perform a long-lived task.

Network related conditions and flags

- Add the InternetAvailable condition (BackgroundTaskBuilder.AddCondition) to your background task to delay triggering the background task until the network stack is running. This condition saves power because the background task won't execute until network access is available. This condition does not provide real-time activation.
- Regardless of the trigger you use, set IsNetworkRequested on your background task to ensure that the network stays up while the background task runs. This tells the background task infrastructure to keep the network up while the task is executing, even if the device has entered Connected Standby mode. If your background task does not use **IsNetworkRequested**, then your background task will not be able to access the network when in Connected Standby mode.

Using background tasks in Windows apps

Article • 03/19/2025

This article provides an overview of using background tasks and describes how to create a new background task in a WinUI 3 app. For information about migrating your UWP apps with background tasks to WinUI, see the Windows App SDK Background task migration strategy.

BackgroundTaskBuilder in the Windows App SDK

Background tasks are app components that run in the background without a user interface. They can perform actions such as downloading files, syncing data, sending notifications, or updating tiles. They can be triggered by various events, such as time, system changes, user actions, or push notifications. These tasks can get executed when corresponding trigger occurs even when the app is not in running state.

The Windows Runtime (WinRT) BackgroundTaskBuilder was designed for UWP applications, and many of the background task triggers are not supported for full trust COM Components. They are supported only when registered with WinRT components that are launched with a `backgroundtaskhost` process. Due to this, Windows App SDK desktop applications can't directly register the full trust COM components to be launched with background task triggers. They require a workaround of including the WinRT components in the project. The BackgroundTaskBuilder in Windows App SDK API avoids this workaround so WinUI 3 and other desktop applications that use Windows App SDK can register the full trust COM components directly with background tasks.

Register a background task

The following example registers a background task for a full trust COM component using the Windows App SDK BackgroundTaskBuilder. See the Background task migration strategy guide for more information.

The C++ code to create and register a background task is as follows:

```
C++
```

```
//Using the Windows App SDK API for BackgroundTaskBuilder
winrt::Microsoft::Windows::ApplicationModel::Background::BackgroundTaskBuild
er builder;
SystemTrigger trigger = SystemTrigger(SystemTriggerType::TimeZoneChange,
false);
auto backgroundTrigger = trigger.as<IBackgroundTrigger>();
builder.SetTrigger(backgroundTrigger);
builder.AddCondition(SystemCondition(SystemConditionType::InternetAvailable)
);
builder.SetTaskEntryPointClsid(classGuid);
builder.Register();
```

To create and register the background task in C#, the code is as follows:

C#

```
//Using the Windows App SDK API for BackgroundTaskBuilder
var builder = new
Microsoft.Windows.ApplicationModel.Background.BackgroundTaskBuilder();
var trigger = new SystemTrigger(SystemTriggerType.TimeZoneChange, false);
var backgroundTrigger = trigger as IBackgroundTrigger;
builder.SetTrigger(backgroundTrigger);
builder.AddCondition(new
SystemCondition(SystemConditionType.InternetAvailable));
builder.SetTaskEntryPointClsid(classGuid);
builder.Register();
```

The corresponding package manifest entry for the background task is as follows:

XML

```
<Extension Category="windows.backgroundTasks"
EntryPoint="Microsoft.Windows.ApplicationModel.Background.UniversalBGTask.Ta
sk">
    <BackgroundTasks>
        <Task Type="general"/>
    </BackgroundTasks>
</Extension>
```

A full WinUI 3 background task registration sample can be found on GitHub.

Audio, video, and camera

Article • 01/16/2025

This article provides an index of development features that are related to scenarios involving audio, video, and camera in Windows apps.

Windows OS features

Windows 10 and later OS releases provide a wide variety of APIs related to audio, video, and camera scenarios for apps. These features are available via a combination of WinRT and Win32 (C++ and COM) APIs provided by the Windows SDK.

WinRT APIs

The following articles provide information about features available via WinRT APIs provided by the Windows SDK.

Expand table

Article	Description
Camera	Learn about how to use the camera or microphone to capture photos, video, or audio.
Media playback	Learn about how to play back audio and video in your apps.
Visual layer	The Visual layer provides a high performance, retained-mode API for graphics, effects and animations, and is the foundation for all UI across Windows devices.
XAML platform	Describes the XAML language and concepts to apps that use a WinRT XAML-based UI, including XAML UI components provided by Windows 10 and later as well as WinUI.

Win32 (C++ and COM) APIs

The following articles provide information about features available via Win32 (C++ and COM) APIs provided by the Windows SDK.

Expand table

Article	Description
Audio and video	Learn about features for integrating audio and video into your apps.
Graphics and gaming	Learn about features involving graphics, gaming, and imaging.
DirectX	Learn about how to use DirectX APIs to create games and other high-performance multimedia apps using 2D and 3D graphics.
Direct2D	Direct2D is a hardware-accelerated, immediate-mode, 2D graphics API that provides high performance and high-quality rendering for 2-D geometry, bitmaps, and text.
Direct3D	Direct3D is a low-level API for drawing primitives with the rendering pipeline, or for performing parallel operations with the compute shader.
GDI	The Windows Graphics Device Interface (GDI) is a low-level graphics API that enables apps to use two-dimensional vector graphics, imaging, and typography.
GDI+	GDI+ improves on GDI by adding new features and by optimizing existing features.

.NET features

The .NET SDK also provides APIs related to audio, video, and camera scenarios for WPF and Windows Forms apps.

Expand table

Article	Description
Graphics (WPF)	Learn about support for multimedia, vector graphics, animation, and content composition in WPF apps.
Multimedia (WPF)	Learn about integrating audio and video into your WPF apps.
Graphics and drawing (Windows Forms)	Learn how to create graphics, draw text, and manipulate graphical images in Windows Forms apps.
SoundPlayer class (Windows Forms)	Learn how to include sounds in your Windows Forms applications.

Camera

Article • 03/31/2025

This section provides guidance for creating WinUI 3 apps that use the camera or microphone to capture photos, video, or audio.

Basic MediaCapture tasks

Expand table

Topic	Description
Capture photos and video in a desktop app with the Windows built-in camera UI	Describes how to use the CameraCaptureUI class to capture photos or videos by using the camera UI built into Windows. This feature allows your app to get a user-captured photo or video with just a few lines of code.
Show the camera preview in a WinUI 3 app	Shows how to quickly display the camera preview stream within a XAML page in a WinUI 3 app.
Basic photo, video, and audio capture with MediaCapture	Shows the simplest way to capture photos and video using the **MediaCapture** class. The **MediaCapture** class exposes a robust set of APIs that provide low-level control over the capture pipeline and enable advanced capture scenarios, but this article is intended to help you add basic media capture to your app quickly and easily.

Advanced MediaCapture tasks

Expand table

Topic	Description
Discover and select camera capabilities with camera profiles	Learn how to use camera profiles to discover and manage the capabilities of different video capture devices. This includes tasks such as selecting profiles that support specific resolutions or frame rates, profiles that support simultaneous access to multiple cameras, and profiles that support HDR.
Set format, resolution, and frame rate for MediaCapture	Learn how to use the **IMediaEncodingProperties** interface to set the resolution and frame rate of the camera preview stream and captured photos and video. It also shows how to ensure that the aspect ratio of the preview stream matches that of the captured media.

Topic	Description
HDR and low-light photo capture	Learn how to use the **AdvancedPhotoCapture** class to capture High Dynamic Range (HDR) and low-light photos.
Manual camera controls for photo and video capture	Learn how to use manual device controls to enable enhanced photo and video capture scenarios including optical image stabilization and smooth zoom.
Manual camera controls for video capture	Learn how to use manual device controls to enable enhanced video capture scenarios including HDR video and exposure priority.
Video stabilization effect for video capture	Learn how to use the video stabilization effect.
Scene analysis for MediaCapture	Shows you how to use the **SceneAnalysisEffect** and the **FaceDetectionEffect** to analyze the content of the media capture preview stream.
Capture a photo sequence with VariablePhotoSequence	Learn how to capture a variable photo sequence, which allows you to capture multiple frames of images in rapid succession and configure each frame to use different focus, flash, ISO, exposure, and exposure compensation settings.
Process media frames with MediaFrameReader	Learn how to use a **MediaFrameReader** with **MediaCapture** to get media frames from one or more available sources, including color, depth, and infrared cameras, audio devices, or even custom frame sources such as those that produce skeletal tracking frames. This feature is designed to be used by apps that perform real-time processing of media frames, such as augmented reality and depth-aware camera apps.
Process audio frames with MediaFrameReader	Learn how to use a **MediaFrameReader** with **MediaCapture** to get audio data from a media frame source.
Detect and respond to audio level changes by the system	Learn how to detect and respond to audio level changes by the system.
Launch the camera settings page	Learn how to launch the Windows Settings app directly to the camera settings page.
Handle the Windows camera privacy setting	Learn how apps should handle the Windows camera privacy setting.
Connect to remote cameras	Learn how to connect to remote cameras and get a **MediaFrameSourceGroup** to retrieve frames from each camera.

Capture photos and video in a desktop app with the Windows built-in camera UI

Article • 03/31/2025

This article describes how to use the CameraCaptureUI class to capture photos or videos by using the camera UI built into Windows. This feature allows your app to get a user-captured photo or video with just a few lines of code.

If you want to provide your own camera UI, or if your scenario requires more robust, low-level control of the capture operation, then you should use the MediaCapture class, and implement your own capture experience. For more information, see Basic photo, video, and audio capture with MediaCapture.

Note that the **CameraCaptureUI** class in the Microsoft.Windows.Media.Capture namespace is not supported for UWP apps. For information on using the UWP version of this feature, see Capture photos and video in a UWP app with the Windows built-in camera UI

Use the CameraCaptureUI class to capture photos

Create a new instance of **CameraCaptureUI**, passing in the AppWindow.Id property of your app window. The PhotoSettings property allows you to specify some constraints on the captured photo, including the file format and maximum resolution and whether UI allows the user to crop the photo after it's captured. The VideoSettings property provides similar properties for video capture, such as the maximum resolution and duration and whether the UI allows the user to trim the video after it's captured.

Call CaptureFileAsync to launch the camera capture UI asynchronously. Use one of the values from the CameraCaptureUIMode to specify whether the UI should allow photo capture, video capture, or both. When **CaptureFileAsync** completes, it will return a StorageFile file object containing the captured photo or video. If the returned object is null it means that either the user cancelled the capture operation or an error occurred.

The following example demonstrates launching the **CameraCaptureUI** for photo capture, specifying the image format as PNG and disabling cropping. In this example the captured photo is set as the source for an Image control.

C#

```
var cameraCaptureUI = new CameraCaptureUI(this.AppWindow.Id);
cameraCaptureUI.PhotoSettings.Format = CameraCaptureUIPhotoFormat.Png;
cameraCaptureUI.PhotoSettings.AllowCropping = false;

// Capture a photo asynchronously
StorageFile photo = await
cameraCaptureUI.CaptureFileAsync(CameraCaptureUIMode.Photo);

if (photo != null)
{
    // Photo capture was successful

    // Show the captured photo in a XAML Image control
    using (IRandomAccessStream fileStream = await
photo.OpenAsync(Windows.Storage.FileAccessMode.Read))
    {
        // Set the image source to the selected bitmap
        BitmapImage bitmapImage = new BitmapImage();
        await bitmapImage.SetSourceAsync(fileStream);
        iCapturedImage.Source = bitmapImage;
    }
} else
{
    // Photo capture failed or was cancelled
}
```

Use the CameraCaptureUI class to capture videos

The following example demonstrates launching the **CameraCaptureUI** for video capture, specifying the maximum video as standard definition and disabling trimming. In this example the captured photo is set as the source for an MediaPlayerElement control.

C#

```
var cameraCaptureUI = new CameraCaptureUI(this.AppWindow.Id);
cameraCaptureUI.VideoSettings.MaxResolution =
CameraCaptureUIMaxVideoResolution.StandardDefinition;
cameraCaptureUI.VideoSettings.AllowTrimming = true;
StorageFile videoFile = await
cameraCaptureUI.CaptureFileAsync(CameraCaptureUIMode.Video);

if (videoFile != null)
```

```
{
    // Video capture was successful

    // Show the captured video in a MediaPlayerElement control
    mediaPlayerElement.Source =
MediaSource.CreateFromStorageFile(videoFile);
    mediaPlayerElement.MediaPlayer.Play();
}
else
{
    // Video capture failed or was cancelled
}
```

Move and rename captured media files

The **CameraCaptureUI** creates randomized names for captured media files, so you may want to rename and move captured files to keep them organized. The following example moves and renames a captured file.

C#

```
StorageFile photo = await
cameraCaptureUI.CaptureFileAsync(CameraCaptureUIMode.Photo);

if (photo != null)
{
    // Move and rename captured photo
    StorageFolder destinationFolder =
    await
ApplicationData.Current.LocalFolder.CreateFolderAsync("ProfilePhotoFolde
r",
        CreationCollisionOption.OpenIfExists);

    await photo.CopyAsync(destinationFolder, "ProfilePhoto.jpg",
NameCollisionOption.ReplaceExisting);
    await photo.DeleteAsync();
}
```

Show the camera preview in a WinUI 3 app

Article • 01/16/2025

In this quickstart, you will learn how to create a basic WinUI 3 camera app that displays the camera preview. In a WinUI 3 app, you use the MediaPlayerElement control in the Microsot.UI.Xaml.Controls namespace to render the camera preview and the WinRT class MediaCapture to access the device's camera preview stream. **MediaCapture** provides APIs for performing a wide range of camera-related tasks such as such as capturing photos and videos and configuring the camera's device driver. See the other articles in this section for details about other **MediaCapture** features.

The code in this walkthrough is adapted from the MediaCapture WinUI 3 sample on github.

> **Tip**
>
> For the UWP version of this article, see **Display the camera preview** in the UWP documentation.

Prerequisites

- Your device must have developer mode enabled. For more information see Enable your device for development.
- Visual Studio 2022 or later with the **Windows application development** workload.

Create a new WinUI 3 app

In Visual Studio, create a new project. In the **Create a new project** dialog, set the language filter to "C#" and the platform filter to "Windows", then select the "Blank App, Packaged (WinUI 3 in desktop)" project template.

Create the UI

The simple UI for this example includes a **MediaPlayerElement** control for displaying the camera preview, a ComboBox that allows you to select from the device's cameras, and buttons for initializing the **MediaCapture** class, starting and stopping the camera

preview, and reseting the sample. We also include a TextBlock for displaying status messages.

In your project's MainWindow.xml file, replace the default **StackPanel** control with the following XAML.

XAML

```
<Grid ColumnDefinitions="4*,*" ColumnSpacing="4">
    <MediaPlayerElement x:Name="mpePreview" Grid.Row="0" Grid.Column="0"
AreTransportControlsEnabled="False" ManipulationMode="None"/>
    <StackPanel Orientation="Vertical"  Grid.Row="0" Grid.Column="1"
HorizontalAlignment="Stretch"  VerticalAlignment="Top">
        <TextBlock Text="Status:" Margin="0,0,10,0"/>
        <TextBlock x:Name="tbStatus" Text=""/>
        <TextBlock Text="Preview Source:" Margin="0,0,10,0"/>
        <ComboBox x:Name="cbDeviceList" HorizontalAlignment="Stretch"
SelectionChanged="cbDeviceList_SelectionChanged"></ComboBox>
        <Button x:Name="bStartMediaCapture" Content="Initialize
MediaCapture" IsEnabled="False" Click="bStartMediaCapture_Click"/>
        <Button x:Name="bStartPreview" Content="Start preview"
IsEnabled="False" Click="bStartPreview_Click"/>
        <Button x:Name="bStopPreview" Content="Stop preview"
IsEnabled="False" Click="bStopPreview_Click"/>
        <Button x:Name="bReset" Content="Reset" Click="bReset_Click" />
    </StackPanel>
</Grid>
```

Update the MainWindow class definition

The rest of the code in this article will be added to the **MainWindow** class definition in your project's MainWindow.xaml.cs file. First, add a few class variables that will persist throughout the lifetime of the window. These variables include:

- A DeviceInformationCollection that will store a DeviceInformation object for each available camera. The **DeviceInformation** object conveys information such as the unique identifier and the friendly name for the camera.
- A **MediaCapture** object that handles interactions with the selected camera's driver and allows you to retrieve the camera's video stream.
- A MediaFrameSource object that represents a source of media frames, such as a video stream.
- A boolean to track when the camera preview is running. Some camera settings can't be changed while the preview is running, so it's a good practice to track the state of the camera preview.

C#

```
private DeviceInformationCollection m_deviceList;
private MediaCapture m_mediaCapture;
private MediaFrameSource m_frameSource;
private MediaPlayer m_mediaPlayer;
private bool m_isPreviewing;
```

Populate the list of available cameras

Next we'll create a helper method to detect the cameras that are present on the current device and populate the **ComboBox** in the UI with the camera names, allowing the user to select a camera to preview.The DeviceInformation.FindAllAsync allows you to query for many different kinds of devices. We use MediaDevice.GetVideoCaptureSelector to retrieve the identifier that specifies that we only want to retrieve video capture devices.

C#

```
private async void PopulateCameraList()
{
    cbDeviceList.Items.Clear();

    m_deviceList = await
DeviceInformation.FindAllAsync(MediaDevice.GetVideoCaptureSelector());

    if(m_deviceList.Count == 0)
    {
        tbStatus.Text = "No video capture devices found.";
        return;
    }

    foreach (var device in m_deviceList)
    {
        cbDeviceList.Items.Add(device.Name);
        bStartMediaCapture.IsEnabled = true;
    }
}
```

Add a call to this helper method to the **MainWindow** class constructor so that the **ComboBox** gets populated when the window loads.

C#

```
public MainWindow()
{
    this.InitializeComponent();

    PopulateCameraList();
```

```
}
```

Initialize the MediaCapture object

Initialize the **MediaCapture** object by calling InitializeAsync, passing in a MediaCaptureInitializationSettings object containing the requested initialization parameters. There are a lot of optional initialization parameters that enable different scenarios. See the API reference page for the complete list. In this simple example we specify a few basic settings, including:

- The VideoDeviceId property specifies the unique identifier of the camera that the **MediaCapture** will attach to. We get the device ID from the **DeviceInformationCollection**, using the selected index of the **ComboBox**.
- The SharingMode property specifies whether the app is requesting shared, read-only access to the camera, which allows you to view and capture from the video stream, or exclusive control of the camera, which allows you to change the camera configuration. Multiple apps can read from a camera simultaneously, but only one app at a time can have exclusive control.
- The StreamingCaptureMode property specifies whether we want to capture video, audio, or audio and video.
- The MediaCaptureMemoryPreference allows us to request to specifically use CPU memory for video frames. The value **Auto** lets the system use GPU memory if it's available.

Before initializing the **MediaCapture** object we call AppCapability.CheckAccess method to determine if the user has denied our app access to the camera in Windows Settings.

> **Note**
>
> Windows allows users to grant or deny access to the device's camera in the Windows Settings app, under **Privacy & Security -> Camera**. When initializing the capture device, apps should check whether they have access to the camera and handle the case where access is denied by the user. For more information, see Handle the Windows camera privacy setting.

The **InitializeAsync** call is made from inside a **try** block so that we can recover if initialization fails. Apps should handle initialization failure gracefully. In this simple example, we'll just display an error message on failure.

```
C#
```

```
private async void bStartMediaCapture_Click(object sender, RoutedEventArgs
e)
{
    if (m_mediaCapture != null)
    {
        tbStatus.Text = "MediaCapture already initialized.";
        return;
    }

    // Supported in Windows Build 18362 and later
    if(AppCapability.Create("Webcam").CheckAccess() !=
AppCapabilityAccessStatus.Allowed)
    {
        tbStatus.Text = "Camera access denied. Launching settings.";

        bool result = await Windows.System.Launcher.LaunchUriAsync(new
Uri("ms-settings:privacy-webcam"));

        if (AppCapability.Create("Webcam").CheckAccess() !=
AppCapabilityAccessStatus.Allowed)
        {
            tbStatus.Text = "Camera access denied in privacy settings.";
            return;
        }
    }

    try
    {
        m_mediaCapture = new MediaCapture();
        var mediaCaptureInitializationSettings = new
MediaCaptureInitializationSettings()
        {
            VideoDeviceId = m_deviceList[cbDeviceList.SelectedIndex].Id,
            SharingMode = MediaCaptureSharingMode.ExclusiveControl,
            StreamingCaptureMode = StreamingCaptureMode.Video,
            MemoryPreference = MediaCaptureMemoryPreference.Auto
        };

        await
m_mediaCapture.InitializeAsync(mediaCaptureInitializationSettings);

        tbStatus.Text = "MediaCapture initialized successfully.";

        bStartPreview.IsEnabled = true;
    }
    catch (Exception ex)
    {
        tbStatus.Text = "Initialize media capture failed: " + ex.Message;
    }
}
```

Initialize the camera preview

When the user clicks the start preview button, we will attempt to create a **MediaFrameSource** for a video stream from the camera device with which the **MediaCapture** object was initialized. The available frame sources are exposed by the MediaCapture.FrameSources property.

To find a frame source that is color video data, as opposed to a depth camera for example, we look for a frame source that has a SourceKind of Color. Some camera drivers provide a dedicated preview stream that is separate from the record stream. To get the preview video stream, we try to select a frame source that has a MediaStreamType of VideoPreview. If no preview streams are found, we can get the record video stream by selecting a **MediaStreamType** of **VideoRecord**. If neither of these frame sources are available, then this capture device can't be used for video preview.

Once we have selected a frame source, we create a new MediaPlayer object that will be rendered by the **MediaPlayerElement** in our UI. We set the Source property of the **MediaPlayer** to a new MediaSource object we create from our selected **MediaFrameSource**.

Call Play on the **MediaPlayer** object to begin rendering the video stream.

C#

```
private void bStartPreview_Click(object sender, RoutedEventArgs e)
{

    m_frameSource = null;

    // Find preview source.
    // The preferred preview stream from a camera is defined by
MediaStreamType.VideoPreview on the RGB camera (SourceKind == color).
    var previewSource = m_mediaCapture.FrameSources.FirstOrDefault(source =>
source.Value.Info.MediaStreamType == MediaStreamType.VideoPreview

&& source.Value.Info.SourceKind == MediaFrameSourceKind.Color).Value;

    if (previewSource != null)
    {
        m_frameSource = previewSource;
    }
    else
    {
        var recordSource = m_mediaCapture.FrameSources.FirstOrDefault(source
=> source.Value.Info.MediaStreamType == MediaStreamType.VideoRecord

&& source.Value.Info.SourceKind == MediaFrameSourceKind.Color).Value;
```

```
        if (recordSource != null)
        {
            m_frameSource = recordSource;
        }
    }

    if (m_frameSource == null)
    {
        tbStatus.Text = "No video preview or record stream found.";
        return;
    }

    // Create MediaPlayer with the preview source
    m_mediaPlayer = new MediaPlayer();
    m_mediaPlayer.RealTimePlayback = true;
    m_mediaPlayer.AutoPlay = false;
    m_mediaPlayer.Source =
MediaSource.CreateFromMediaFrameSource(m_frameSource);
    m_mediaPlayer.MediaFailed += MediaPlayer_MediaFailed; ;

    // Set the mediaPlayer on the MediaPlayerElement
    mpePreview.SetMediaPlayer(m_mediaPlayer);

    // Start preview
    m_mediaPlayer.Play();

    tbStatus.Text = "Start preview succeeded!";
    m_isPreviewing = true;
    bStartPreview.IsEnabled = false;
    bStopPreview.IsEnabled = true;
}
```

Implement a handler for the MediaFailed event so that you can handle errors rendering the preview.

C#

```
private void MediaPlayer_MediaFailed(MediaPlayer sender,
MediaPlayerFailedEventArgs args)
{
    tbStatus.Text = "MediaPlayer error: " + args.ErrorMessage;
}
```

Stop the camera preview

To stop the camera preview, call Pause on the **MediaPlayer** object.

C#

```
private void bStopPreview_Click(object sender, RoutedEventArgs e)
{
    // Stop preview
    m_mediaPlayer.Pause();
    m_isPreviewing = false;
    bStartPreview.IsEnabled = true;
    bStopPreview.IsEnabled = false;
}
```

Reset the app

To make it easier to test out the sample app, add a method to reset the state of the app. Camera apps should always dispose of the camera and associated resources when the camera is no longer needed.

C#

```
private void bReset_Click(object sender, RoutedEventArgs e)
{
    if (m_mediaCapture != null)
    {
        m_mediaCapture.Dispose();
        m_mediaCapture = null;
    }

    if(m_mediaPlayer != null)
    {
        m_mediaPlayer.Dispose();
        m_mediaPlayer = null;
    }

    m_frameSource = null;

    bStartMediaCapture.IsEnabled = false;
    bStartPreview.IsEnabled = false;
    bStopPreview.IsEnabled = false;

    PopulateCameraList();

}
```

Basic photo, video, and audio capture with MediaCapture in a WinUI 3 app

Article • 01/16/2025

This article shows the simplest way to capture photos and video using the MediaCapture class. The **MediaCapture** class exposes a robust set of APIs that provide low-level control over the capture pipeline and enable advanced capture scenarios, but this article is intended to help you add basic media capture to your app quickly and easily. To learn about more of the features that **MediaCapture** provides, see Camera.

Initialize the MediaCapture object

All of the capture methods described in this article require the first step of initializing the MediaCapture object. This includes instantiating the object, selecting a capture device, setting initialization parameters, and then calling InitializeAsync. Typically camera apps will display the camera preview while capturing photos or video in their UI using the MediaPlayerElement. For a walkthrough of initializing **MediaCapture** and showing the preview in a XAML UI, see Show the camera preview in a WinUI 3 app. The code examples in this article will assume that an initialized instance of **MediaCapture** has already been created.

Capture a photo to a SoftwareBitmap

The SoftwareBitmap class provides a common representation of images across multiple features. If you want to capture a photo and then immediately use the captured image in your app, such as displaying it in XAML, instead of capturing to a file, then you should capture to a **SoftwareBitmap**. You still have the option of saving the image to disk later.

Capture a photo to a **SoftwareBitmap** using the LowLagPhotoCapture class. Get an instance of this class by calling PrepareLowLagPhotoCaptureAsync, passing in an ImageEncodingProperties object specifying the image format you want. CreateUncompressed creates an uncompressed encoding with the specified pixel format. Initiate photo capture by calling CaptureAsync, which returns a CapturedPhoto object. Get a **SoftwareBitmap** by accessing the Frame property and then the SoftwareBitmap property.

You can capture multiple photos by repeatedly calling **CaptureAsync**. When you are done capturing, call FinishAsync to shut down the **LowLagPhotoCapture** session and free up the associated resources. After calling **FinishAsync**, to begin capturing photos

again you will need to call PrepareLowLagPhotoCaptureAsync again to reinitialize the capture session before calling CaptureAsync.

```
C#

// Prepare and capture photo
var lowLagCapture = await
m_mediaCapture.PrepareLowLagPhotoCaptureAsync(ImageEncodingProperties.Create
Uncompressed(MediaPixelFormat.Bgra8));

var capturedPhoto = await lowLagCapture.CaptureAsync();
var softwareBitmap = capturedPhoto.Frame.SoftwareBitmap;

// Capture more photos, if desired.
// Then call FinishAsync to clean up resources
await lowLagCapture.FinishAsync();
```

Capture a photo to a memory stream

You can use **MediaCapture** to capture a photo to an in-memory stream, which you can then use to transcode the photo from the stream to a file on disk.

Create an InMemoryRandomAccessStream and then call CapturePhotoToStreamAsync to capture a photo to the stream, passing in the stream and an ImageEncodingProperties object specifying the image format that should be used. You can create custom encoding properties by initializing the object yourself, but the class provides static methods, like ImageEncodingProperties.CreateJpeg for common encoding formats.

Create a BitmapDecoder to decode the image from the in memory stream. Create a BitmapEncoder to encode the image to file by calling CreateForTranscodingAsync.

You can optionally create a BitmapPropertySet object and then call SetPropertiesAsync on the image encoder to include metadata about the photo in the image file. For more information about encoding properties, see Image metadata.

Finally, call FlushAsync on the encoder object to transcode the photo from the in-memory stream to the file.

```
C#

// Prepare and capture photo
var lowLagCapture = await
m_mediaCapture.PrepareLowLagPhotoCaptureAsync(ImageEncodingProperties.Create
Uncompressed(MediaPixelFormat.Bgra8));
```

```
var capturedPhoto = await lowLagCapture.CaptureAsync();
var softwareBitmap = capturedPhoto.Frame.SoftwareBitmap;

// Capture more photos, if desired.
// Then call FinishAsync to clean up resources
await lowLagCapture.FinishAsync();
```

Capture a video

Quickly add video capture to your app by using the **LowLagMediaRecording** class.

First, the **LowLagMediaRecording** needs to persist while video is being captured, so declare a class variable to for the object.

C#

```
LowLagMediaRecording m_mediaRecording;
```

Call **PrepareLowLagRecordToStorageFileAsync** to initialize the media recording, passing in the storage file and a **MediaEncodingProfile** object specifying the encoding for the video. The class provides static methods, like **CreateMp4**, for creating common video encoding profiles. Call **StartAsync** to begin capturing video.

C#

```
var myVideos = await
Windows.Storage.StorageLibrary.GetLibraryAsync(Windows.Storage.KnownLibraryI
d.Videos);
StorageFile file = await myVideos.SaveFolder.CreateFileAsync("video.mp4",
CreationCollisionOption.GenerateUniqueName);
m_mediaRecording = await
m_mediaCapture.PrepareLowLagRecordToStorageFileAsync(
        MediaEncodingProfile.CreateMp4(VideoEncodingQuality.Auto), file);

m_mediaCapture.RecordLimitationExceeded +=
m_mediaCapture_RecordLimitationExceeded;
await m_mediaRecording.StartAsync();
```

To stop recording video, call **StopAsync**.

C#

```
await m_mediaRecording.StopAsync();
```

You can continue to call **StartAsync** and **StopAsync** to capture additional videos. When you are done capturing videos, call **FinishAsync** to dispose of the capture session and clean up associated resources. After this call, you must call **PrepareLowLagRecordToStorageFileAsync** again to reinitialize the capture session before calling **StartAsync**.

```
C#

await m_mediaRecording.FinishAsync();
```

When capturing video, you should register a handler for the **RecordLimitationExceeded** event of the **MediaCapture** object, which will be raised by the operating system if you surpass the limit for a single recording, currently three hours. In the handler for the event, you should finalize your recording by calling **StopAsync**.

```
C#

private async void m_mediaCapture_RecordLimitationExceeded(MediaCapture
sender)
{
    await m_mediaRecording.StopAsync();
    DispatcherQueue.TryEnqueue(() =>
    {
        tbStatus.Text = "Record limitation exceeded.";
    });
}
```

You can pause a video recording and then resume recording without creating a separate output file by calling **PauseAsync** and then calling **ResumeAsync**.

```
C#

await
m_mediaRecording.PauseAsync(Windows.Media.Devices.MediaCapturePauseBehavior.
ReleaseHardwareResources);
```

```
C#

await m_mediaRecording.ResumeAsync();
```

Calling **PauseWithResultAsync** returns a **MediaCapturePauseResult** object. The **LastFrame** property is a **VideoFrame** object representing the last frame. To display the frame in XAML, get the **SoftwareBitmap** representation of the video frame. Currently, only images in BGRA8 format with premultiplied or empty alpha channel are supported,

so call **Convert** if necessary to get the correct format. **PauseWithResultAsync** also returns the duration of the video that was recorded in the preceding segment in case you need to track how much total time has been recorded.

You can also get a result frame when you stop the video by calling **StopWithResultAsync**.

Play and edit captured video files

Once you have captured a video to a file, you may want to load the file and play it back within your app's UI. You can do this using the **MediaPlayerElement** XAML control and an associated **MediaPlayer**. For information on playing media in a XAML page, see Play audio and video with MediaPlayer.

[TBD - Is the MediaComposition framework supported / recommended for WinUI?]

You can also create a **MediaClip** object from a video file by calling **CreateFromFileAsync**. A **MediaComposition** provides basic video editing functionality like arranging the sequence of **MediaClip** objects, trimming video length, creating layers, adding background music, and applying video effects. For more information on working with media compositions, see Media compositions and editing.

Capture audio

You can quickly add audio capture to your app by using the same technique shown above for capturing video. Call **PrepareLowLagRecordToStorageFileAsync** to initialize the capture session, passing in the file and a **MediaEncodingProfile** which is generated in this example by the **CreateMp3** static method. To begin recording, call **StartAsync**.

[TBD - This code is throwing 'The request is invalid in the current state.']

C#

```
m_mediaCapture.RecordLimitationExceeded +=
m_mediaCapture_RecordLimitationExceeded;

var myVideos = await
Windows.Storage.StorageLibrary.GetLibraryAsync(Windows.Storage.KnownLibraryI
d.Videos);
StorageFile file = await myVideos.SaveFolder.CreateFileAsync("audio.mp3",
CreationCollisionOption.GenerateUniqueName);
m_mediaRecording = await
m_mediaCapture.PrepareLowLagRecordToStorageFileAsync(
```

```
        MediaEncodingProfile.CreateMp3(AudioEncodingQuality.High), file);
await m_mediaRecording.StartAsync();
```

Call **StopAsync** to stop the audio recording.

```
C#

await m_mediaRecording.StopAsync();
```

You can call **StartAsync** and **StopAsync** multiple times to record several audio files. When you are done capturing audio, call **FinishAsync** to dispose of the capture session and clean up associated resources. After this call, you must call **PrepareLowLagRecordToStorageFileAsync** again to reinitialize the capture session before calling **StartAsync**.

For information about detecting when the system changes the audio level of the audio capture stream, see Detect and respond to audio level changes by the system.

Discover and select camera capabilities with camera profiles in a WinUI 3 app

Article • 01/16/2025

This article shows how to use camera profiles to discover and manage the capabilities of different video capture devices. This includes tasks such as selecting profiles that support specific resolutions or frame rates, profiles that support simultaneous access to multiple cameras, and profiles that support HDR.

About camera profiles

Cameras on different devices support different capabilities including the set of supported capture resolutions, frame rate for video captures, and whether HDR or variable frame rate captures are supported. A set of supported capabilities is defined in a **MediaCaptureVideoProfileMediaDescription** object. A camera profile, represented by a **MediaCaptureVideoProfile** object, has three collections of media descriptions; one for photo capture, one for video capture, and another for video preview.

Before initializing your **MediaCapture** object, you can query the capture devices on the current device to see what profiles are supported. When you select a supported profile, you know that the capture device supports all of the capabilities in the profile's media descriptions. This eliminates the need for a trial and error approach to determining which combinations of capabilities are supported on a particular device.

Find a camera that supports camera profiles

To use camera profiles, you must first check for a camera device that supports the use of camera profiles. The example below shows how to use the **DeviceInformation.FindAllAsync** method to retrieve a list of all available video capture devices on either the front or back panel of the current device. It loops through all of the devices in the list, calling the static method, **IsVideoProfileSupported**, for each device to see if it supports video profiles.

If a device that supports camera profiles is found on the specified panel, the **Id** value, containing the device's ID string, is returned.

XAML

```
public async Task<string>
GetVideoProfileSupportedDeviceIdAsync(Windows.Devices.Enumeration.Panel
```

```
panel)
{
    string deviceId = string.Empty;

    // Finds all video capture devices
    DeviceInformationCollection devices = await
DeviceInformation.FindAllAsync(DeviceClass.VideoCapture);

    foreach (var device in devices)
    {
        // Check if the device on the requested panel supports Video Profile
        if (MediaCapture.IsVideoProfileSupported(device.Id) &&
device.EnclosureLocation.Panel == panel)
        {
            // We've located a device that supports Video Profiles on
expected panel
            deviceId = device.Id;
            break;
        }
    }

    return deviceId;
}
```

If the device ID returned from the **GetVideoProfileSupportedDeviceIdAsync** helper method is null or an empty string, there is no device on the specified panel that supports camera profiles. In this case, you should initialize your media capture device without using profiles.

XAML

```
string videoDeviceId = await
GetVideoProfileSupportedDeviceIdAsync(Windows.Devices.Enumeration.Panel.Back
);

if (string.IsNullOrEmpty(videoDeviceId))
{
    // No devices on the specified panel support video profiles. .
    return;
}
```

Select a profile based on supported resolution and frame rate

To select a profile with particular capabilities, such as with the ability to achieve a particular resolution and frame rate, use the method shown previously in this article to get the ID of a capture device that supports using camera profiles.

Create a new MediaCaptureInitializationSettings object, passing in the selected device ID. Call the static method MediaCapture.FindAllVideoProfiles to get a list of all camera profiles supported by the device.

This example selects a profile that contains a SupportedRecordMediaDescription object where the Width, Height, and FrameRate properties match the requested values. If a match is found, VideoProfile and RecordMediaDescription of the **MediaCaptureInitializationSettings** are set to the values returned from the query. If no match is found, the default profile is used.

XAML

```
var mediaInitSettings = new MediaCaptureInitializationSettings {
VideoDeviceId = videoDeviceId };

IReadOnlyList<MediaCaptureVideoProfile> profiles =
MediaCapture.FindAllVideoProfiles(videoDeviceId);

var match = (from profile in profiles
             from desc in profile.SupportedRecordMediaDescription
             where desc.Width == 640 && desc.Height == 480 &&
Math.Round(desc.FrameRate) == 30
             select new { profile, desc }).FirstOrDefault();

if (match != null)
{
    mediaInitSettings.VideoProfile = match.profile;
    mediaInitSettings.RecordMediaDescription = match.desc;
}
else
{
    // Could not locate a WVGA 30FPS profile, use default video recording
profile
    mediaInitSettings.VideoProfile = profiles[0];
}
```

After you populate the **MediaCaptureInitializationSettings** with your desired camera profile, you simply call InitializeAsync on your media capture object to configure it to the desired profile.

XAML

```
await m_mediaCapture.InitializeAsync(mediaInitSettings);
```

Select devices with KnownVideoProfile

You can use the **MediaFrameSourceGroup** class to get camera profiles with specific capabilities before initializing the **MediaCapture** object. Frame source groups allow device manufacturers to represent groups of sensors or capture capabilities as a single virtual device. This enables computational photography scenarios such as using depth and color cameras together, but can also be used to select camera profiles for simple capture scenarios. For more information on using **MediaFrameSourceGroup**, see Process media frames with MediaFrameReader.

The example below shows how to use **MediaFrameSourceGroup** to find a camera profile that supports that supports the desired scenario. Call **MediaFrameSourceGroup.FindAllAsync** to get a list of all media frame source groups available on the current device. Loop through each source group and call **MediaCapture.FindKnownVideoProfiles** to get a list of all of the video profiles for the current source group that support the specified KnownCameraProfile, in this example the value **KnownVideoProfile.HighQualityPhoto** is used. Other values include support for HDR and variable photo sequences, for example. If a profile that meets the requested criteria is found, create a new **MediaCaptureInitializationSettings** object and set the **VideoProfile** to the select profile and the **VideoDeviceId** to the **Id** property of the current media frame source group. Use this **MediaCaptureInitializationSettings** object to initialize the **MediaCapture** object.

XAML

```
IReadOnlyList<MediaFrameSourceGroup> sourceGroups = await
MediaFrameSourceGroup.FindAllAsync();
MediaCaptureInitializationSettings settings = null;

foreach (MediaFrameSourceGroup sg in sourceGroups)
{

    IReadOnlyList<MediaCaptureVideoProfile> profileList =
MediaCapture.FindKnownVideoProfiles(
                                    sg.Id,
                                    KnownVideoProfile.HighQualityPhoto);

    if (profileList.Count > 0)
    {
        settings = new MediaCaptureInitializationSettings();
        settings.VideoProfile = profileList[0];
        settings.VideoDeviceId = sg.Id;
        break;
    }
}
```

Determine if a device supports simultaneous photo and video capture

Many devices support capturing photos and video simultaneously. To determine if a capture device supports this, call **MediaCapture.FindAllVideoProfiles** to get all of the camera profiles supported by the device. Use a link query to find a profile that has at least one entry for both **SupportedPhotoMediaDescription** and **SupportedRecordMediaDescription** which means that the profile supports simultaneous capture.

XAML

```
bool simultaneousPhotoAndVideoSupported = false;

IReadOnlyList<MediaCaptureVideoProfile> profiles =
MediaCapture.FindAllVideoProfiles(videoDeviceId);

var match = (from profile in profiles
             where profile.SupportedPhotoMediaDescription.Any() &&
             profile.SupportedRecordMediaDescription.Any()
             select profile).FirstOrDefault();

if (match != null)
{
    // Simultaneous photo and video supported
    simultaneousPhotoAndVideoSupported = true;
}
else
{
    // Simultaneous photo and video not supported
    simultaneousPhotoAndVideoSupported = false;
}
```

You can refine this query to look for profiles that support specific resolutions or other capabilities in addition to simultaneous video record. You can also use the **MediaCapture.FindKnownVideoProfiles** and specify the **BalancedVideoAndPhoto** value to retrieve profiles that support simultaneous capture, but querying all profiles will provide more complete results.

Set format, resolution, and frame rate for MediaCapture in a WinUI 3 app

Article • 01/16/2025

This article shows you how to use the **IMediaEncodingProperties** interface to set the resolution and frame rate of the camera preview stream and captured photos and video. It also shows how to ensure that the aspect ratio of the preview stream matches that of the captured media.

Camera profiles offer a simpler, higher level mechanism for discovering and setting the stream properties of the camera, but they are not supported for all devices. For more information, see Camera profiles.

Determine if the preview and capture streams are independent

On some devices, the same hardware pin is used for both preview and capture streams. On these devices, setting the encoding properties such as the format, resolution and frame rate on one will affect both. On devices that use different hardware pins for capture and preview, the properties can be set for each stream independently. Use the following code to determine if the preview and capture streams are independent. This example sets a boolean global variable that can be used to switch the app's behavior if the streams are shared or independent.

C#

```
if (m_mediaCapture.MediaCaptureSettings.VideoDeviceCharacteristic ==
VideoDeviceCharacteristic.AllStreamsIdentical ||
    m_mediaCapture.MediaCaptureSettings.VideoDeviceCharacteristic ==
VideoDeviceCharacteristic.PreviewRecordStreamsIdentical)
{
    m_captureAndPreviewStreamsIdentical = true;
}
```

A media encoding properties helper class

Creating a simple helper class to wrap the functionality of the **IMediaEncodingProperties** interface makes it easier to select a set of encoding properties that meet particular criteria. This helper class is particularly useful due to the following behavior of the encoding properties feature:

> **Note**
>
> The VideoDeviceController.GetAvailableMediaStreamProperties method takes a member of the MediaStreamType enumeration, such as **VideoRecord** or **Photo**, and returns a list of either ImageEncodingProperties or VideoEncodingProperties objects that convey the stream encoding settings, such as the resolution of the captured photo or video. The results of calling **GetAvailableMediaStreamProperties** may include **ImageEncodingProperties** or **VideoEncodingProperties** regardless of what **MediaStreamType** value is specified. For this reason, you should always check the type of each returned value and cast it to the appropriate type before attempting to access any of the property values.

The helper class defined below handles the type checking and casting for ImageEncodingProperties or VideoEncodingProperties so that your app code doesn't need to distinguish between the two types. In addition to this, the helper class exposes properties for the aspect ratio of the properties, the frame rate (for video encoding properties only), and a friendly name that makes it easier to display the encoding properties in your UI.

C#

```
class StreamPropertiesHelper
{
    private IMediaEncodingProperties _properties;

    public StreamPropertiesHelper(IMediaEncodingProperties properties)
    {
        if (properties == null)
        {
            throw new ArgumentNullException(nameof(properties));
        }

        // This helper class only uses ImageEncodingProperties or
VideoEncodingProperties
        if (!(properties is ImageEncodingProperties) && !(properties is
VideoEncodingProperties))
        {
            throw new ArgumentException("Argument is of the wrong type.
Required: " + typeof(ImageEncodingProperties).Name
                + " or " + typeof(VideoEncodingProperties).Name + ".",
nameof(properties));
        }

        // Store the actual instance of the IMediaEncodingProperties for
setting them later
        _properties = properties;
    }
```

```
    public uint Width
    {
        get
        {
            if (_properties is ImageEncodingProperties)
            {
                return (_properties as ImageEncodingProperties).Width;
            }
            else if (_properties is VideoEncodingProperties)
            {
                return (_properties as VideoEncodingProperties).Width;
            }

            return 0;
        }
    }

    public uint Height
    {
        get
        {
            if (_properties is ImageEncodingProperties)
            {
                return (_properties as ImageEncodingProperties).Height;
            }
            else if (_properties is VideoEncodingProperties)
            {
                return (_properties as VideoEncodingProperties).Height;
            }

            return 0;
        }
    }

    public uint FrameRate
    {
        get
        {
            if (_properties is VideoEncodingProperties)
            {
                if ((_properties as
VideoEncodingProperties).FrameRate.Denominator != 0)
                {
                    return (_properties as
VideoEncodingProperties).FrameRate.Numerator /
                           (_properties as
VideoEncodingProperties).FrameRate.Denominator;
                }
            }

            return 0;
        }
    }
```

```
    public double AspectRatio
    {
        get { return Math.Round((Height != 0) ? (Width / (double)Height) :
double.NaN, 2); }
    }

    public IMediaEncodingProperties EncodingProperties
    {
        get { return _properties; }
    }

    public string GetFriendlyName(bool showFrameRate = true)
    {
        if (_properties is ImageEncodingProperties ||
            !showFrameRate)
        {
            return Width + "x" + Height + " [" + AspectRatio + "] " +
_properties.Subtype;
        }
        else if (_properties is VideoEncodingProperties)
        {
            return Width + "x" + Height + " [" + AspectRatio + "] " +
FrameRate + "FPS " + _properties.Subtype;
        }

        return String.Empty;
    }

}
```

Get a list of available stream properties

Get a list of the available stream properties for a capture device by getting the VideoDeviceController for your app's MediaCapture object and then calling GetAvailableMediaStreamProperties and passing in one of the MediaStreamType values, **VideoPreview**, **VideoRecord**, or **Photo**. In this example, a list of **StreamPropertiesHelper** objects, defined previously in this article, is created for each of the IMediaEncodingProperties values returned from **GetAvailableMediaStreamProperties**. This example orders the returned properties based first on resolution and then on frame rate.

If your app has specific resolution or frame rate requirements, you can select a set of media encoding properties programmatically. A typical camera app will instead expose the list of available properties in the UI and allow the user to select their desired settings. A **ComboBoxItem** is created for each item in the list of **StreamPropertiesHelper** objects in the list. The content is set to the friendly name returned by the helper class and the tag is set to the helper class itself so it can be used

later to retrieve the associated encoding properties. Each **ComboBoxItem** is then added to a **ComboBox** defined in the UI.

C#

```
private void bGetStreamProperties_Click(object sender, RoutedEventArgs e)
{
    // Query all properties of the specified stream type
    IEnumerable<StreamPropertiesHelper> allStreamProperties =

m_mediaCapture.VideoDeviceController.GetAvailableMediaStreamProperties(Media
StreamType.VideoRecord).Select(x => new StreamPropertiesHelper(x));

    // Order them by resolution then frame rate
    allStreamProperties = allStreamProperties.OrderByDescending(x =>
x.Height * x.Width).ThenByDescending(x => x.FrameRate);

    // Populate the combo box with the entries
    foreach (var property in allStreamProperties)
    {
        ComboBoxItem comboBoxItem = new ComboBoxItem();
        comboBoxItem.Content = property.GetFriendlyName();
        comboBoxItem.Tag = property;
        cbStreamProperties.Items.Add(comboBoxItem);
    }
}
```

Set the desired stream properties

Tell the video device controller to use your desired encoding properties by calling SetMediaStreamPropertiesAsync, passing in the **MediaStreamType** value indicating whether the photo, video, or preview properties should be set. This example uses the **ComboBox** populated in the example from the previous section, where the media stream properties are retrieved from the tag property from the selected item.

C#

```
private async void bSetStreamProperties_Click(object sender, RoutedEventArgs
e)
{

    if (m_exclusiveCameraAccess)
    {
        var selectedItem = cbStreamProperties.SelectedItem as ComboBoxItem;
        var encodingProperties = (selectedItem.Tag as
StreamPropertiesHelper).EncodingProperties;
        await
m_mediaCapture.VideoDeviceController.SetMediaStreamPropertiesAsync(MediaStre
amType.VideoPreview, encodingProperties);
```

```
    }
}
```

Note that your app must have exclusive control of the capture device in order to change the media stream properties.

Match the aspect ratio of the preview and capture streams

A typical camera app will provide UI for the user to select the video or photo capture resolution but will programmatically set the preview resolution. There are a few different strategies for selecting the best preview stream resolution for your app:

- Select the highest available preview resolution, letting the UI framework perform any necessary scaling of the preview.
- Select the preview resolution closest to the capture resolution so that the preview displays the closest representation to the final captured media.
- Select the preview resolution closest to the size of the **CaptureElement** so that no more pixels than necessary are going through the preview stream pipeline.

> **Note**
>
> It is possible, on some devices, to set a different aspect ratio for the camera's preview stream and capture stream. Frame cropping caused by this mismatch can result in content being present in the captured media that was not visible in the preview which can result in a negative user experience. It is strongly recommended that you use the same aspect ratio, within a small tolerance window, for the preview and capture streams. It is fine to have entirely different resolutions enabled for capture and preview as long as the aspect ratio match closely.

To ensure that the photo or video capture streams match the aspect ratio of the preview stream, this example calls **VideoDeviceController.GetMediaStreamProperties** and passes in the **VideoPreview** enum value to request the current stream properties for the preview stream. Next a small aspect ratio tolerance window is defined so that we can include aspect ratios that are not exactly the same as the preview stream, as long as they are close. Next, the **StreamPropertiesHelper** objects where the aspect ratio is within the defined tolerance range of the preview stream are selected.

```
C#
```

```
// Query all properties of the specified stream type
IEnumerable<StreamPropertiesHelper> allVideoProperties =

m_mediaCapture.VideoDeviceController.GetAvailableMediaStreamProperties(Media
StreamType.VideoRecord).Select(x => new StreamPropertiesHelper(x));

// Query the current preview settings
StreamPropertiesHelper previewProperties = new
StreamPropertiesHelper(m_mediaCapture.VideoDeviceController.GetMediaStreamPr
operties(MediaStreamType.VideoPreview));

// Get all formats that have the same-ish aspect ratio as the preview
// Allow for some tolerance in the aspect ratio comparison
const double ASPECT_RATIO_TOLERANCE = 0.015;
var matchingFormats = allVideoProperties.Where(x => Math.Abs(x.AspectRatio -
previewProperties.AspectRatio) < ASPECT_RATIO_TOLERANCE);

// Order them by resolution then frame rate
allVideoProperties = matchingFormats.OrderByDescending(x => x.Height *
x.Width).ThenByDescending(x => x.FrameRate);

// Clear out old entries and populate the video combo box with new matching
entries
cbStreamProperties.Items.Clear();
foreach (var property in allVideoProperties)
{
    ComboBoxItem comboBoxItem = new ComboBoxItem();
    comboBoxItem.Content = property.GetFriendlyName();
    comboBoxItem.Tag = property;
    cbStreamProperties.Items.Add(comboBoxItem);
}
```

SnippetMatchPreviewAspectRatio

High dynamic range (HDR) and low-light photo capture

Article • 01/16/2025

This article shows you how to use the **AdvancedPhotoCapture** class to capture high dynamic range (HDR) photos. This API also allows you to obtain a reference frame from the HDR capture before the processing of the final image is complete.

Other articles related to HDR capture include:

- You can use the **SceneAnalysisEffect** to allow the system to evaluate the content of the media capture preview stream to determine if HDR processing would improve the capture result. For more information, see Scene analysis for MediaCapture.
- Use the **HdrVideoControl** to capture video using the Windows built-in HDR processing algorithm. For more information, see Capture device controls for video capture.
- You can use the **VariablePhotoSequenceCapture** to capture a sequence of photos, each with different capture settings, and implement your own HDR or other processing algorithm. For more information, see Variable photo sequence.

> **Note**
>
> Starting with Windows 10, version 1709, recording video and using **AdvancedPhotoCapture** concurrently is supported. This is not supported in previous versions. This change means that you can have a prepared LowLagMediaRecording and AdvancedPhotoCapture at the same time. You can start or stop video recording between calls to MediaCapture.PrepareAdvancedPhotoCaptureAsync and AdvancedPhotoCapture.FinishAsync. You can also call AdvancedPhotoCapture.CaptureAsync while video is recording. However, some **AdvancedPhotoCapture** scenarios, like capturing an HDR photo while recording video would cause some video frames to be altered by the HDR capture, resulting in a negative user experience. For this reason, the list of modes returned by the AdvancedPhotoControl.SupportedModes will be different while video is recording. You should check this value immediately after starting or stopping video recording to ensure that the desired mode is supported in the current video recording state.

> **Note**
>
> Starting with Windows 10, version 1709, when the **AdvancedPhotoCapture** is set to HDR mode, the setting of the FlashControl.Enabled property is ignored and the flash is never fired. For other capture modes, if the **FlashControl.Enabled**, it will override the **AdvancedPhotoCapture** settings and cause a normal photo to be captured with flash. If Auto is set to true, the **AdvancedPhotoCapture** may or may not use flash, depending on the camera driver's default behavior for the conditions in the current scene. On previous releases, the **AdvancedPhotoCapture** flash setting always overrides the **FlashControl.Enabled** setting.

There is a full sample demonstrating the use of the **AdvancedPhotoCapture** class that you can use to see the API used in context or as a starting point for your own app. For more information see, Camera Advanced Capture sample.

HDR photo capture

Determine if HDR photo capture is supported on the current device

The HDR capture technique described in this article is performed using the AdvancedPhotoCapture object. Not all devices support HDR capture with **AdvancedPhotoCapture**. Determine if the device on which your app is currently running supports the technique by getting the **MediaCapture** object's VideoDeviceController and then getting the AdvancedPhotoControl property. Check the video device controller's SupportedModes collection to see if it includes AdvancedPhotoMode.Hdr. If it does, HDR capture using **AdvancedPhotoCapture** is supported.

C#

```
m_hdrSupported =
m_mediaCapture.VideoDeviceController.AdvancedPhotoControl.SupportedModes.Con
tains(Windows.Media.Devices.AdvancedPhotoMode.Hdr);
```

Configure and prepare the AdvancedPhotoCapture object

Because you will need to access the AdvancedPhotoCapture instance from multiple places within your code, you should declare a member variable to hold the object.

C#

```
private AdvancedPhotoCapture m_advancedCapture;
```

In your app, after you have initialized the **MediaCapture** object, create an AdvancedPhotoCaptureSettings object and set the mode to AdvancedPhotoMode.Hdr. Call the AdvancedPhotoControl object's Configure method, passing in the **AdvancedPhotoCaptureSettings** object you created.

Call the **MediaCapture** object's PrepareAdvancedPhotoCaptureAsync, passing in an ImageEncodingProperties object specifying the type of encoding the capture should use. The **ImageEncodingProperties** class provides static methods for creating the image encodings that are supported by **MediaCapture**.

PrepareAdvancedPhotoCaptureAsync returns the AdvancedPhotoCapture object you will use to initiate photo capture. You can use this object to register handlers for the OptionalReferencePhotoCaptured and AllPhotosCaptured which are discussed later in this article.

C#

```
if (m_hdrSupported == false) return;

// Choose HDR mode
var settings = new AdvancedPhotoCaptureSettings { Mode =
AdvancedPhotoMode.Hdr };

// Configure the mode
m_mediaCapture.VideoDeviceController.AdvancedPhotoControl.Configure(settings
);

// Prepare for an advanced capture
m_advancedCapture =
    await
m_mediaCapture.PrepareAdvancedPhotoCaptureAsync(ImageEncodingProperties.Crea
teUncompressed(MediaPixelFormat.Nv12));

// Register for events published by the AdvancedCapture
m_advancedCapture.AllPhotosCaptured += M_advancedCapture_AllPhotosCaptured;
m_advancedCapture.OptionalReferencePhotoCaptured +=
M_advancedCapture_OptionalReferencePhotoCaptured;
```

Capture an HDR photo

Capture an HDR photo by calling the AdvancedPhotoCapture object's CaptureAsync method. This method returns an AdvancedCapturedPhoto object that provides the captured photo in its Frame property. Next, the photo is saved to disk.

C#

```
try
{

    // Start capture, and pass the context object
    AdvancedCapturedPhoto advancedCapturedPhoto = await
m_advancedCapture.CaptureAsync();

    using (var frame = advancedCapturedPhoto.Frame)
    {
        var fileName = String.Format("SimplePhoto_{0}_HDR.jpg",
DateTime.Now.ToString("HHmmss"));
        StorageFile photoFile = await
KnownFolders.PicturesLibrary.CreateFileAsync(fileName);
        IRandomAccessStream stream = await
photoFile.OpenAsync(FileAccessMode.ReadWrite);
        await
RandomAccessStream.CopyAndCloseAsync(advancedCapturedPhoto.Frame, stream);
    }
}
catch (Exception ex)
{
    Debug.WriteLine("Exception when taking an HDR photo: {0}",
ex.ToString());
}
```

Get optional reference frame

The HDR process captures multiple frames and then composites them into a single image after all of the frames have been captured. You can get access to a frame after it is captured but before the entire HDR process is complete by handling the OptionalReferencePhotoCaptured event. You don't need to do this if you are only interested in the final HDR photo result.

> ⓘ **Important**
>
> OptionalReferencePhotoCaptured is not raised on devices that support hardware HDR and therefore do not generate reference frames. Your app should handle the case where this event is not raised.

Because the reference frame arrives out of context of the call to **CaptureAsync**, a mechanism is provided to pass context information to the **OptionalReferencePhotoCaptured** handler. First you should call an object that will contain your context information. The name and contents of this object is up to you.

This example defines an object that has members to track the file name and camera orientation of the capture.

C#

```
public class MyAdvancedCaptureContextObject
{
    public string CaptureFileName;
    public PhotoOrientation CaptureOrientation;
}
```

Create a new instance of your context object, populate its members, and then pass it into the overload of **CaptureAsync** that accepts an object as a parameter.

C#

```
// Add the the capture time to the file name
var fileName = String.Format("SimplePhoto_{0}_HDR.jpg",
DateTime.Now.ToString("HHmmss"));

// Create a context object, to identify the capture in the
OptionalReferencePhotoCaptured event
var context = new MyAdvancedCaptureContextObject()
{
    CaptureFileName = fileName,
};

// Start capture, and pass the context object
AdvancedCapturedPhoto advancedCapturedPhoto = await
m_advancedCapture.CaptureAsync(context);
```

In the **OptionalReferencePhotoCaptured** event handler, cast the **Context** property of the **OptionalReferencePhotoCapturedEventArgs** object to your context object class. This example modifies the file name to distinguish the reference frame image from the final HDR image and then saves the image to disk.

C#

```
private async void
M_advancedCapture_OptionalReferencePhotoCaptured(AdvancedPhotoCapture
sender, OptionalReferencePhotoCapturedEventArgs args)
{
    // Retrieve the context (i.e. what capture does this belong to?)
    var context = args.Context as MyAdvancedCaptureContextObject;

    // Remove "_HDR" from the name of the capture to create the name of the
reference
    var referenceName = context.CaptureFileName.Replace("_HDR", "");
```

```
    using (var frame = args.Frame)
    {
        await SaveCapturedFrameAsync(frame, referenceName,
context.CaptureOrientation);
    }
}
```

Receive a notification when all frames have been captured

The HDR photo capture has two steps. First, multiple frames are captured, and then the frames are processed into the final HDR image. You can't initiate another capture while the source HDR frames are still being captured, but you can initiate a capture after all of the frames have been captured but before the HDR post-processing is complete. The **AllPhotosCaptured** event is raised when the HDR captures are complete, letting you know that you can initiate another capture. A typical scenario is to disable your UI's capture button when HDR capture begins and then reenable it when **AllPhotosCaptured** is raised.

C#

```
private void M_advancedCapture_AllPhotosCaptured(AdvancedPhotoCapture
sender, object args)
{
    // Update UI to enable capture button
}
```

Clean up the AdvancedPhotoCapture object

When your app is done capturing, before disposing of the **MediaCapture** object, you should shut down the **AdvancedPhotoCapture** object by calling **FinishAsync** and setting your member variable to null.

C#

```
await m_advancedCapture.FinishAsync();
m_advancedCapture = null;
```

Low-light photo capture

Starting with Windows 10, version 1607, **AdvancedPhotoCapture** can be used to capture photos using a built-in algorithm that enhances the quality of photos captured in low-

light settings. When you use the low-light feature of the AdvancedPhotoCapture class, the system will evaluate the current scene and, if needed, apply an algorithm to compensate for low-light conditions. If the system determines that the algorithm is not needed, a regular capture is performed instead.

Before using low-light photo capture, determine if the device on which your app is currently running supports the technique by getting the **MediaCapture** object's VideoDeviceController and then getting the AdvancedPhotoControl property. Check the video device controller's SupportedModes collection to see if it includes AdvancedPhotoMode.LowLight. If it does, low-light capture using **AdvancedPhotoCapture** is supported.

C#

```
m_lowLightSupported =
m_mediaCapture.VideoDeviceController.AdvancedPhotoControl.SupportedModes.Con
tains(Windows.Media.Devices.AdvancedPhotoMode.LowLight);
```

In your app, after you have initialized the **MediaCapture** object, create an AdvancedPhotoCaptureSettings object and set the mode to AdvancedPhotoMode.LowLight. Call the AdvancedPhotoControl object's Configure method, passing in the **AdvancedPhotoCaptureSettings** object you created.

Call the **MediaCapture** object's PrepareAdvancedPhotoCaptureAsync, passing in an ImageEncodingProperties object specifying the type of encoding the capture should use.

C#

```
if (m_lowLightSupported == false) return;

// Choose LowLight mode
var settings = new AdvancedPhotoCaptureSettings { Mode =
AdvancedPhotoMode.LowLight };
m_mediaCapture.VideoDeviceController.AdvancedPhotoControl.Configure(settings
);

// Prepare for an advanced capture
m_advancedCapture =
    await
m_mediaCapture.PrepareAdvancedPhotoCaptureAsync(ImageEncodingProperties.Crea
teJpeg());
```

To capture a photo, call CaptureAsync.

C#

```
AdvancedCapturedPhoto advancedCapturedPhoto = await
m_advancedCapture.CaptureAsync();
StorageFile photoFile = await
KnownFolders.PicturesLibrary.CreateFileAsync($"Photo_{advancedCapturedPhoto.
Mode}.jpg", CreationCollisionOption.GenerateUniqueName);
IRandomAccessStream stream = await
photoFile.OpenAsync(FileAccessMode.ReadWrite);
await RandomAccessStream.CopyAndCloseAsync(advancedCapturedPhoto.Frame,
stream);
```

You can capture multiple low-light photos without reconfiguring the **AdvancedPhotoCapture** object, but when you are done capturing, you should call FinishAsync to clean up the object and associated resources.

C#

```
await m_advancedCapture.FinishAsync();
m_advancedCapture = null;
```

Working with AdvancedCapturedPhoto objects

AdvancedPhotoCapture.CaptureAsync returns an AdvancedCapturedPhoto object representing the captured photo. This object exposes the Frame property which returns a CapturedFrame object representing the image. The OptionalReferencePhotoCaptured event also provides a **CapturedFrame** object in its event args. After you get an object of this type, there are a number of things you can do with it, including creating a SoftwareBitmap or saving the image to a file.

Get a SoftwareBitmap from a CapturedFrame

Get a **SoftwareBitmap** from a **CapturedFrame** object by simply accessing the SoftwareBitmap property of the object. However, most encoding formats do not support **SoftwareBitmap** with **AdvancedPhotoCapture**, so you should check and make sure the property is not null before using it.

C#

```
SoftwareBitmap bitmap;
if (advancedCapturedPhoto.Frame.SoftwareBitmap != null)
{
    bitmap = advancedCapturedPhoto.Frame.SoftwareBitmap;
}
```

In the current release, the only encoding format that supports **SoftwareBitmap** for **AdvancedPhotoCapture** is uncompressed NV12. So, if you want to use this feature, you must specify that encoding when you call **PrepareAdvancedPhotoCaptureAsync**.

C#

```
m_advancedCapture =
    await
m_mediaCapture.PrepareAdvancedPhotoCaptureAsync(ImageEncodingProperties.Crea
teUncompressed(MediaPixelFormat.Nv12));
```

Of course, you can always save the image to a file and then load the file into a **SoftwareBitmap** in a separate step. For more information about working with **SoftwareBitmap**, see **Create, edit, and save bitmap images**.

Manual camera controls for photo and video capture

Article • 01/16/2025

This article shows you how to use manual device controls to enable enhanced photo and video capture scenarios including optical image stabilization and smooth zoom.

The controls discussed in this article are all added to your app using the same pattern. First, check to see if the control is supported on the current device on which your app is running. If the control is supported, set the desired mode for the control. Typically, if a particular control is unsupported on the current device, you should disable or hide the UI element that allows the user to enable the feature.

> **Note**
>
> This article builds on concepts and code discussed in Basic photo, video, and audio capture with MediaCapture, which describes the steps for implementing basic photo and video capture. We recommend that you familiarize yourself with the basic media capture pattern in that article before moving on to more advanced capture scenarios. The code in this article assumes that your app already has an instance of **MediaCapture** that has been properly initialized.

Exposure

The **ExposureControl** allows you to set the shutter speed used during photo or video capture.

This example uses a **Slider** control to adjust the current exposure value and a checkbox to toggle automatic exposure adjustment.

XML

```
<Slider Name="slExposure" ValueChanged="slExposure_ValueChanged"/>
<TextBlock Name="tbExposure" Text="{Binding
ElementName=slExposure,Path=Value}"/>
<CheckBox Name="cbExposureAuto" Content="Auto"
Checked="cbExposure_CheckedChanged" Unchecked="cbExposure_CheckedChanged"/>
```

Check to see if the current capture device supports the **ExposureControl** by checking the **Supported** property. If the control is supported, you can show and enable the UI for

this feature. Set the checked state of the checkbox to indicate if automatic exposure adjustment is currently active to the value of the **Auto** property.

The exposure value must be within the range supported by the device and must be an increment of the supported step size. Get the supported values for the current device by checking the **Min**, **Max**, and **Step** properties, which are used to set the corresponding properties of the slider control.

Set the slider control's value to the current value of the **ExposureControl** after unregistering the **ValueChanged** event handler so that the event is not triggered when the value is set.

C#

```
var exposureControl = m_mediaCapture.VideoDeviceController.ExposureControl;

if (exposureControl.Supported)
{
    cbExposureAuto.Visibility = Visibility.Visible;
    slExposure.Visibility = Visibility.Visible;

    cbExposureAuto.IsChecked = exposureControl.Auto;

    slExposure.Minimum = exposureControl.Min.Ticks;
    slExposure.Maximum = exposureControl.Max.Ticks;
    slExposure.StepFrequency = exposureControl.Step.Ticks;

    slExposure.ValueChanged -= slExposure_ValueChanged;
    var value = exposureControl.Value;
    slExposure.Value = value.Ticks;
    slExposure.ValueChanged += slExposure_ValueChanged;
}
else
{
    cbExposureAuto.Visibility = Visibility.Collapsed;
    slExposure.Visibility = Visibility.Collapsed;
}
```

In the **ValueChanged** event handler, get the current value of the control and the set the exposure value by calling **SetValueAsync**.

C#

```
private async void slExposure_ValueChanged(object sender,
Microsoft.UI.Xaml.Controls.Primitives.RangeBaseValueChangedEventArgs e)
{
    var value = TimeSpan.FromTicks((long)(sender as Slider).Value);
    await
```

```
m_mediaCapture.VideoDeviceController.ExposureControl.SetValueAsync(value);
}
```

In the **CheckedChanged** event handler of the auto exposure checkbox, turn automatic exposure adjustment on or off by calling **SetAutoAsync** and passing in a boolean value.

C#

```
private async void cbExposure_CheckedChanged(object sender, RoutedEventArgs
e)
{
    if (!m_isPreviewing)
    {
        // Auto exposure only supported while preview stream is running.
        return;
    }

    var autoExposure = ((sender as CheckBox).IsChecked == true);
    await
m_mediaCapture.VideoDeviceController.ExposureControl.SetAutoAsync(autoExposu
re);
}
```

> **ⓘ Important**
>
> Automatic exposure mode is only supported while the preview stream is running. Check to make sure that the preview stream is running before turning on automatic exposure.

Exposure compensation

The **ExposureCompensationControl** allows you to set the exposure compensation used during photo or video capture.

This example uses a **Slider** control to adjust the current exposure compensation value.

XML

```
<Slider Name="slEV" ValueChanged="slEV_ValueChanged"/>
<TextBlock Text="{Binding ElementName=slEV,Path=Value}" Name="tbEV"/>
```

Check to see if the current capture device supports the **ExposureCompensationControl** by checking the Supported property. If the control is supported, you can show and enable the UI for this feature.

The exposure compensation value must be within the range supported by the device and must be an increment of the supported step size. Get the supported values for the current device by checking the **Min**, **Max**, and **Step** properties, which are used to set the corresponding properties of the slider control.

Set slider control's value to the current value of the **ExposureCompensationControl** after unregistering the **ValueChanged** event handler so that the event is not triggered when the value is set.

C#

```
var exposureCompensationControl =
m_mediaCapture.VideoDeviceController.ExposureCompensationControl;

if (exposureCompensationControl.Supported)
{
    slEV.Visibility = Visibility.Visible;
    slEV.Minimum = exposureCompensationControl.Min;
    slEV.Maximum = exposureCompensationControl.Max;
    slEV.StepFrequency = exposureCompensationControl.Step;

    slEV.ValueChanged -= slEV_ValueChanged;
    slEV.Value = exposureCompensationControl.Value;
    slEV.ValueChanged += slEV_ValueChanged;
}
else
{
    slEV.Visibility = Visibility.Collapsed;
}
```

In the **ValueChanged** event handler, get the current value of the control and the set the exposure value by calling **SetValueAsync**.

C#

```
private async void slEV_ValueChanged(object sender,
Microsoft.UI.Xaml.Controls.Primitives.RangeBaseValueChangedEventArgs e)
{
    var value = (sender as Slider).Value;
    await
m_mediaCapture.VideoDeviceController.ExposureCompensationControl.SetValueAsy
nc((float)value);
}
```

Flash

The FlashControl allows you to enable or disable the flash or to enable automatic flash, where the system dynamically determines whether to use the flash. This control also allows you to enable automatic red eye reduction on devices that support it. These settings all apply to capturing photos. The TorchControl is a separate control for turning the torch on or off for video capture.

This example uses a set of radio buttons to allow the user to switch between on, off, and auto flash settings. A checkbox is also provided to allow toggling of red eye reduction and the video torch.

XML

```
<RadioButton Name="rbFlashOn" Content="On" Checked="rbFlashOn_Checked"/>
<RadioButton Name="rbFlashAuto" Content="Auto"
Checked="rbFlashAuto_Checked"/>
<RadioButton Name="rbFlashOff" Content="Off" Checked="rbFlashOff_Checked"/>
<CheckBox Name="cbRedEyeFlash" Content="Red Eye" Visibility="Collapsed"
Checked="cbRedEyeFlash_CheckedChanged"
Unchecked="cbRedEyeFlash_CheckedChanged"/>
<CheckBox Name="cbTorch" Content="Video Light" Visibility="Collapsed"
Checked="cbTorch_CheckedChanged" Unchecked="cbTorch_CheckedChanged"/>
```

Check to see if the current capture device supports the **FlashControl** by checking the Supported property. If the control is supported, you can show and enable the UI for this feature. If the **FlashControl** is supported, automatic red eye reduction may or may not be supported, so check the RedEyeReductionSupported property before enabling the UI. Because the **TorchControl** is separate from the flash control, you must also check its Supported property before using it.

In the Checked event handler for each of the flash radio buttons, enable or disable the appropriate corresponding flash setting. Note that to set the flash to always be used, you must set the Enabled property to true and the Auto property to false.

C#

```
var flashControl = m_mediaCapture.VideoDeviceController.FlashControl;

if (flashControl.Supported)
{
    rbFlashAuto.Visibility = Visibility.Visible;
    rbFlashOn.Visibility = Visibility.Visible;
    rbFlashOff.Visibility = Visibility.Visible;

    rbFlashAuto.IsChecked = true;

    if (flashControl.RedEyeReductionSupported)
    {
        cbRedEyeFlash.Visibility = Visibility.Visible;
```

```
    }

    // Video light is not strictly part of flash, but users might expect to
find it there
    if (m_mediaCapture.VideoDeviceController.TorchControl.Supported)
    {
        cbTorch.Visibility = Visibility.Visible;
    }
}
else
{
    rbFlashAuto.Visibility = Visibility.Collapsed;
    rbFlashOn.Visibility = Visibility.Collapsed;
    rbFlashOff.Visibility = Visibility.Collapsed;
}
```

C#

```
private void rbFlashOn_Checked(object sender, RoutedEventArgs e)
{
    m_mediaCapture.VideoDeviceController.FlashControl.Enabled = true;
    m_mediaCapture.VideoDeviceController.FlashControl.Auto = false;
}

private void rbFlashAuto_Checked(object sender, RoutedEventArgs e)
{
    m_mediaCapture.VideoDeviceController.FlashControl.Enabled = true;
    m_mediaCapture.VideoDeviceController.FlashControl.Auto = true;
}

private void rbFlashOff_Checked(object sender, RoutedEventArgs e)
{
    m_mediaCapture.VideoDeviceController.FlashControl.Enabled = false;
}
```

In the handler for the red eye reduction checkbox, set the **RedEyeReduction** property to the appropriate value.

C#

```

//private void cbRedEyeFlash_CheckedChanged(object sender, RoutedEventArgs
e)
private void cbRedEyeFlash_CheckedChanged(object sender, RoutedEventArgs e)
{
    m_mediaCapture.VideoDeviceController.FlashControl.RedEyeReduction =
(cbRedEyeFlash.IsChecked == true);
}
```

Finally, in the handler for the video torch checkbox, set the **Enabled** property to the appropriate value.

C#

```
private void cbTorch_CheckedChanged(object sender, RoutedEventArgs e)
{
    m_mediaCapture.VideoDeviceController.TorchControl.Enabled =
(cbTorch.IsChecked == true);

    if(! (m_isPreviewing && m_isRecording))
    {
        System.Diagnostics.Debug.WriteLine("Torch may not emit light if
preview and video capture are not running.");
    }
}
```

> **Note**
>
> On some devices the torch will not emit light, even if TorchControl.Enabled is set to true, unless the device has a preview stream running and is actively capturing video. The recommended order of operations is to turn on the video preview, turn on the torch by setting **Enabled** to true, and then initiate video capture. On some devices the torch will light up after the preview is started. On other devices, the torch may not light up until video capture is started.

Focus

Three different commonly used methods for adjusting the focus of the camera are supported by the **FocusControl** object, continuous autofocus, tap to focus, and manual focus. A camera app may support all three of these methods, but for readability, this article discusses each technique separately. This section also discusses how to enable the focus assist light.

Continuous autofocus

Enabling continuous autofocus instructs the camera to adjust the focus dynamically to try to keep the subject of the photo or video in focus. This example uses a radio button to toggle continuous autofocus on and off.

XML

```
<RadioButton Content="CAF" Name="rbContinuousAutoFocus"
Checked="rbContinuousAutoFocus_Checked"/>
```

Check to see if the current capture device supports the **FocusControl** by checking the **Supported** property. Next, determine if continuous autofocus is supported by checking the **SupportedFocusModes** list to see if it contains the value **FocusMode.Continuous**, and if so, show the continuous autofocus radio button.

C#

```
var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;

if (focusControl.Supported)
{
    rbContinuousAutoFocus.Visibility =
focusControl.SupportedFocusModes.Contains(FocusMode.Continuous)
        ? Visibility.Visible : Visibility.Collapsed;
}
else
{
    rbContinuousAutoFocus.Visibility = Visibility.Collapsed;
}
```

In the **Checked** event handler for the continuous autofocus radio button, use the **VideoDeviceController.FocusControl** property to get an instance of the control. Call **UnlockAsync** to unlock the control in case your app has previously called **LockAsync** to enable one of the other focus modes.

Create a new **FocusSettings** object and set the **Mode** property to **Continuous**. Set the **AutoFocusRange** property to a value appropriate for your app scenario or selected by the user from your UI. Pass your **FocusSettings** object into the **Configure** method, and then call **FocusAsync** to initiate continuous autofocus.

C#

```
private async void rbContinuousAutoFocus_Checked(object sender,
RoutedEventArgs e)
{
    if(! m_isPreviewing)
    {
        // Autofocus only supported while preview stream is running.
        return;
    }

    var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;
    await focusControl.UnlockAsync();
    var settings = new FocusSettings { Mode = FocusMode.Continuous,
```

```
AutoFocusRange = AutoFocusRange.FullRange };
    focusControl.Configure(settings);
    await focusControl.FocusAsync();
}
```

> **ⓘ Important**
>
> Autofocus mode is only supported while the preview stream is running. Check to make sure that the preview stream is running before turning on continuous autofocus.

Tap to focus

The tap-to-focus technique uses the **FocusControl** and the **RegionsOfInterestControl** to specify a subregion of the capture frame where the capture device should focus. The region of focus is determined by the user tapping on the screen displaying the preview stream.

This example uses a radio button to enable and disable tap-to-focus mode.

XML

```
<RadioButton Content="rbTapToFocus" Name="TapFocusRadioButton"
Checked="rbTapToFocus_Checked"/>
```

Check to see if the current capture device supports the **FocusControl** by checking the **Supported** property. The **RegionsOfInterestControl** must be supported, and must support at least one region, in order to use this technique. Check the **AutoFocusSupported** and **MaxRegions** properties to determine whether to show or hide the radio button for tap-to-focus.

C#

```
var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;

if (focusControl.Supported)
{
    TapFocusRadioButton.Visibility =
(m_mediaCapture.VideoDeviceController.RegionsOfInterestControl.AutoFocusSupp
orted &&

m_mediaCapture.VideoDeviceController.RegionsOfInterestControl.MaxRegions >
0)
                                        ? Visibility.Visible :
Visibility.Collapsed;
```

```
}
else
{
    TapFocusRadioButton.Visibility = Visibility.Collapsed;
}
```

In the **Checked** event handler for the tap-to-focus radio button, use the **VideoDeviceController.FocusControl** property to get an instance of the control. Call **LockAsync** to lock the control in case your app has previously called **UnlockAsync** to enable continuous autofocus, and then wait for the user to tap the screen to change the focus.

C#

```
private async void rbTapToFocus_Checked(object sender, RoutedEventArgs e)
{
    // Lock focus in case Continuous Autofocus was active when switching to
Tap-to-focus
    var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;
    await focusControl.LockAsync();
    // Wait for user tap
}
```

This example focuses on a region when the user taps the screen, and then removes the focus from that region when the user taps again, like a toggle. Use a boolean variable to track the current toggled state.

C#

```
bool _isFocused = false;
```

The next step is to listen for the event when the user taps the screen by handling the **Tapped** event of the **CaptureElement** that is currently displaying the capture preview stream. If the camera isn't currently previewing, or if tap-to-focus mode is disabled, return from the handler without doing anything.

If the tracking variable *_isFocused* is toggled to false, and if the camera isn't currently in the process of focus (determined by the **FocusState** property of the **FocusControl**), begin the tap-to-focus process. Get the position of the user's tap from the event args passed into the handler. This example also uses this opportunity to pick the size of the region that will be focused upon. In this case, the size is 1/4 of the smallest dimension of the capture element. Pass the tap position and the region size into the **TapToFocus** helper method that is defined in the next section.

If the *_isFocused* toggle is set to true, the user tap should clear the focus from the previous region. This is done in the **TapUnfocus** helper method shown below.

C#

```
private async void mpePreview_Tapped(object sender, TappedRoutedEventArgs e)
{
    if (!m_isPreviewing || (TapFocusRadioButton.IsChecked != true)) return;

    if (!_isFocused &&
m_mediaCapture.VideoDeviceController.FocusControl.FocusState !=
MediaCaptureFocusState.Searching)
    {
        var smallEdge = Math.Min(Window.Current.Bounds.Width,
Window.Current.Bounds.Height);

        // Choose to make the focus rectangle 1/4th the length of the
shortest edge of the window
        var size = new Size(smallEdge / 4, smallEdge / 4);
        var position = e.GetPosition(sender as UIElement);

        // Note that at this point, a rect at "position" with size "size"
could extend beyond the preview area. The following method will reposition
the rect if that is the case
        await TapToFocus(position, size);
    }
    else
    {
        await TapUnfocus();
    }
}
```

In the **TapToFocus** helper method, first set the *_isFocused* toggle to true so that the next screen tap will release the focus from the tapped region.

The next task in this helper method is to determine the rectangle within the preview stream that will be assigned to the focus control. This requires two steps. The first step is to determine the rectangle that the preview stream takes up within the CaptureElement control. This depends on the dimensions of the preview stream and the orientation of the device. The helper method **GetPreviewStreamRectInControl**, shown at the end of this section, performs this task and returns the rectangle containing the preview stream.

The next task in **TapToFocus** is to convert the tap location and desired focus rectangle size, which were determined within the **CaptureElement.Tapped** event handler, into coordinates within capture stream. The **ConvertUiTapToPreviewRect** helper method, shown later in this section, performs this conversion and returns the rectangle, in capture stream coordinates, where the focus will be requested.

Now that the target rectangle has been obtained, create a new **RegionOfInterest** object, setting the **Bounds** property to the target rectangle obtained in the previous steps.

Get the capture device's **FocusControl**. Create a new **FocusSettings** object and set the **Mode** and **AutoFocusRange** to your desired values, after checking to make sure that they are supported by the **FocusControl**. Call **Configure** on the **FocusControl** to make your settings active and signal the device to begin focusing on the specified region.

Next, get the capture device's **RegionsOfInterestControl** and call **SetRegionsAsync** to set the active region. Multiple regions of interest can be set on devices that support it, but this example only sets a single region.

Finally, call **FocusAsync** on the **FocusControl** to initiate focusing.

> **ⓘ Important**
>
> When implementing tap to focus, the order of operations is important. You should call these APIs in the following order:
>
> 1. FocusControl.Configure
> 2. RegionsOfInterestControl.SetRegionsAsync
> 3. FocusControl.FocusAsync

C#

```
public async Task TapToFocus(Point position, Size size)
{
    _isFocused = true;

    var previewRect = GetPreviewStreamRectInControl();
    var focusPreview = ConvertUiTapToPreviewRect(position, size,
previewRect);

    // Note that this Region Of Interest could be configured to also
calculate exposure
    // and white balance within the region
    var regionOfInterest = new RegionOfInterest
    {
        AutoFocusEnabled = true,
        BoundsNormalized = true,
        Bounds = focusPreview,
        Type = RegionOfInterestType.Unknown,
        Weight = 100,
    };

    var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;
```

```
    var focusRange =
focusControl.SupportedFocusRanges.Contains(AutoFocusRange.FullRange) ?
AutoFocusRange.FullRange :
focusControl.SupportedFocusRanges.FirstOrDefault();
    var focusMode =
focusControl.SupportedFocusModes.Contains(FocusMode.Single) ?
FocusMode.Single : focusControl.SupportedFocusModes.FirstOrDefault();
    var settings = new FocusSettings { Mode = focusMode, AutoFocusRange =
focusRange };
    focusControl.Configure(settings);

    var roiControl =
m_mediaCapture.VideoDeviceController.RegionsOfInterestControl;
    await roiControl.SetRegionsAsync(new[] { regionOfInterest }, true);

    await focusControl.FocusAsync();
}
```

In the **TapUnfocus** helper method, obtain the **RegionsOfInterestControl** and call **ClearRegionsAsync** to clear the region that was registered with the control within the **TapToFocus** helper method. Then, get the **FocusControl** and call **FocusAsync** to cause the device to refocus without a region of interest.

C#

```
private async Task TapUnfocus()
{
    _isFocused = false;

    var roiControl =
m_mediaCapture.VideoDeviceController.RegionsOfInterestControl;
    await roiControl.ClearRegionsAsync();

    var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;
    await focusControl.FocusAsync();
}
```

The **GetPreviewStreamRectInControl** helper method uses the resolution of the preview stream and the orientation of the device to determine the rectangle within the preview element that contains the preview stream, trimming off any letterboxed padding that the control may provide to maintain the stream's aspect ratio. This method uses class member variables defined in the basic media capture example code found in Basic photo, video, and audio capture with MediaCapture.

C#

```
public Rect GetPreviewStreamRectInControl()
{
    var result = new Rect();
```

```
    var previewResolution =
m_mediaCapture.VideoDeviceController.GetMediaStreamProperties(MediaStreamTyp
e.VideoPreview) as VideoEncodingProperties;

    // In case this function is called before everything is initialized
correctly, return an empty result
    if (mpePreview == null || mpePreview.ActualHeight < 1 ||
mpePreview.ActualWidth < 1 ||
        previewResolution == null || previewResolution.Height == 0 ||
previewResolution.Width == 0)
    {
        return result;
    }

    var streamWidth = previewResolution.Width;
    var streamHeight = previewResolution.Height;

    // For portrait orientations, the width and height need to be swapped
    if (m_displayOrientation == DisplayOrientations.Portrait ||
m_displayOrientation == DisplayOrientations.PortraitFlipped)
    {
        streamWidth = previewResolution.Height;
        streamHeight = previewResolution.Width;
    }

    // Start by assuming the preview display area in the control spans the
entire width and height both (this is corrected in the next if for the
necessary dimension)
    result.Width = mpePreview.ActualWidth;
    result.Height = mpePreview.ActualHeight;

    // If UI is "wider" than preview, letterboxing will be on the sides
    if ((mpePreview.ActualWidth / mpePreview.ActualHeight > streamWidth /
(double)streamHeight))
    {
        var scale = mpePreview.ActualHeight / streamHeight;
        var scaledWidth = streamWidth * scale;

        result.X = (mpePreview.ActualWidth - scaledWidth) / 2.0;
        result.Width = scaledWidth;
    }
    else // Preview stream is "wider" than UI, so letterboxing will be on
the top+bottom
    {
        var scale = mpePreview.ActualWidth / streamWidth;
        var scaledHeight = streamHeight * scale;

        result.Y = (mpePreview.ActualHeight - scaledHeight) / 2.0;
        result.Height = scaledHeight;
    }

    return result;
}
```

The **ConvertUiTapToPreviewRect** helper method takes as arguments the location of the tap event, the desired size of the focus region, and the rectangle containing the preview stream obtained from the **GetPreviewStreamRectInControl** helper method. This method uses these values and the device's current orientation to calculate the rectangle within the preview stream that contains the desired region. Once again, this method uses class member variables defined in the basic media capture example code found in Capture Photos and Video with MediaCapture.

C#

```
private Rect ConvertUiTapToPreviewRect(Point tap, Size size, Rect
previewRect)
{
    // Adjust for the resulting focus rectangle to be centered around the
position
    double left = tap.X - size.Width / 2, top = tap.Y - size.Height / 2;

    // Get the information about the active preview area within the
CaptureElement (in case it's letterboxed)
    double previewWidth = previewRect.Width, previewHeight =
previewRect.Height;
    double previewLeft = previewRect.Left, previewTop = previewRect.Top;

    // Transform the left and top of the tap to account for rotation
    switch (m_displayOrientation)
    {
        case DisplayOrientations.Portrait:
            var tempLeft = left;

            left = top;
            top = previewRect.Width - tempLeft;
            break;
        case DisplayOrientations.LandscapeFlipped:
            left = previewRect.Width - left;
            top = previewRect.Height - top;
            break;
        case DisplayOrientations.PortraitFlipped:
            var tempTop = top;

            top = left;
            left = previewRect.Width - tempTop;
            break;
    }

    // For portrait orientations, the information about the active preview
area needs to be rotated
    if (m_displayOrientation == DisplayOrientations.Portrait ||
m_displayOrientation == DisplayOrientations.PortraitFlipped)
    {
        previewWidth = previewRect.Height;
        previewHeight = previewRect.Width;
        previewLeft = previewRect.Top;
```

```
            previewTop = previewRect.Left;
        }

        // Normalize width and height of the focus rectangle
        var width = size.Width / previewWidth;
        var height = size.Height / previewHeight;

        // Shift rect left and top to be relative to just the active preview
area
        left -= previewLeft;
        top -= previewTop;

        // Normalize left and top
        left /= previewWidth;
        top /= previewHeight;

        // Ensure rectangle is fully contained within the active preview area
horizontally
        left = Math.Max(left, 0);
        left = Math.Min(1 - width, left);

        // Ensure rectangle is fully contained within the active preview area
vertically
        top = Math.Max(top, 0);
        top = Math.Min(1 - height, top);

        // Create and return resulting rectangle
        return new Rect(left, top, width, height);
    }
```

Manual focus

The manual focus technique uses a **Slider** control to set the current focus depth of the capture device. A radio button is used to toggle manual focus on and off.

XML

```
<Slider Name="slFocus" IsEnabled="{Binding
ElementName=rbManualFocus,Path=IsChecked}"
ValueChanged="slFocus_ValueChanged"/>
<TextBlock Text="{Binding
ElementName=slFocus,Path=Value,FallbackValue='0'}"/>
<RadioButton Content="Manual" Name="rbManualFocus"
Checked="rbManualFocus_Checked" IsChecked="False"/>
```

Check to see if the current capture device supports the **FocusControl** by checking the **Supported** property. If the control is supported, you can show and enable the UI for this feature.

The focus value must be within the range supported by the device and must be an increment of the supported step size. Get the supported values for the current device by checking the **Min**, **Max**, and **Step** properties, which are used to set the corresponding properties of the slider control.

Set the slider control's value to the current value of the **FocusControl** after unregistering the **ValueChanged** event handler so that the event is not triggered when the value is set.

```
C#
```

```
var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;

if (focusControl.Supported)
{
    slFocus.Visibility = Visibility.Visible;
    rbManualFocus.Visibility = Visibility.Visible;

    slFocus.Minimum = focusControl.Min;
    slFocus.Maximum = focusControl.Max;
    slFocus.StepFrequency = focusControl.Step;

    slFocus.ValueChanged -= slFocus_ValueChanged;
    slFocus.Value = focusControl.Value;
    slFocus.ValueChanged += slFocus_ValueChanged;
}
else
{
    slFocus.Visibility = Visibility.Collapsed;
    rbManualFocus.Visibility = Visibility.Collapsed;
}
```

In the **Checked** event handler for the manual focus radio button, get the **FocusControl** object and call **LockAsync** in case your app had previously unlocked the focus with a call to **UnlockAsync**.

```
C#
```

```
private async void rbManualFocus_Checked(object sender, RoutedEventArgs e)
{
    var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;
    await focusControl.LockAsync();
}
```

In the **ValueChanged** event handler of the manual focus slider, get the current value of the control and the set the focus value by calling **SetValueAsync**.

```
C#
```

```
private async void slFocus_ValueChanged(object sender,
Microsoft.UI.Xaml.Controls.Primitives.RangeBaseValueChangedEventArgs e)
{
    var value = (sender as Slider).Value;
    await
m_mediaCapture.VideoDeviceController.FocusControl.SetValueAsync((uint)value)
;
}
```

Enable the focus light

On devices that support it, you can enable a focus assist light to help the device focus. This example uses a checkbox to enable or disable the focus assist light.

XML

```
<CheckBox Content="Assist Light" Name="cbFocusLight" IsEnabled="{Binding
ElementName=rbTapToFocus,Path=IsChecked}"
Checked="cbFocusLight_CheckedChanged"
Unchecked="cbFocusLight_CheckedChanged"/>
```

Check to see if the current capture device supports the **FlashControl** by checking the **Supported** property. Also check the **AssistantLightSupported** to make sure the assist light is also supported. If these are both supported, you can show and enable the UI for this feature.

C#

```
var focusControl = m_mediaCapture.VideoDeviceController.FocusControl;

if (focusControl.Supported)
{

    cbFocusLight.Visibility =
(m_mediaCapture.VideoDeviceController.FlashControl.Supported &&

m_mediaCapture.VideoDeviceController.FlashControl.AssistantLightSupported) ?
Visibility.Visible : Visibility.Collapsed;
}
else
{
    cbFocusLight.Visibility = Visibility.Collapsed;
}
```

In the **CheckedChanged** event handler, get the capture devices **FlashControl** object. Set the **AssistantLightEnabled** property to enable or disable the focus light.

C#

```
private void cbFocusLight_CheckedChanged(object sender, RoutedEventArgs e)
{
    var flashControl = m_mediaCapture.VideoDeviceController.FlashControl;

    flashControl.AssistantLightEnabled = (cbFocusLight.IsChecked == true);
}
```

ISO speed

The **IsoSpeedControl** allows you to set the ISO speed used during photo or video capture.

This example uses a **Slider** control to adjust the current exposure compensation value and a checkbox to toggle automatic ISO speed adjustment.

XML

```
<Slider Name="slIso" ValueChanged="slIso_ValueChanged"/>
<TextBlock Text="{Binding ElementName=slIso,Path=Value}" Visibility="
{Binding ElementName=slIso,Path=Visibility}"/>
<CheckBox Name="cbIsoAuto" Content="Auto" Checked="cbIsoAuto_CheckedChanged"
Unchecked="cbIsoAuto_CheckedChanged"/>
```

Check to see if the current capture device supports the **IsoSpeedControl** by checking the **Supported** property. If the control is supported, you can show and enable the UI for this feature. Set the checked state of the checkbox to indicate if automatic ISO speed adjustment is currently active to the value of the **Auto** property.

The ISO speed value must be within the range supported by the device and must be an increment of the supported step size. Get the supported values for the current device by checking the **Min**, **Max**, and **Step** properties, which are used to set the corresponding properties of the slider control.

Set the slider control's value to the current value of the **IsoSpeedControl** after unregistering the **ValueChanged** event handler so that the event is not triggered when the value is set.

C#

```
private void bUpdateIsoControlCapabilities_Click(object sender,
RoutedEventArgs e)
{
    var isoSpeedControl =
m_mediaCapture.VideoDeviceController.IsoSpeedControl;
```

```
    if (isoSpeedControl.Supported)
    {
        cbIsoAuto.Visibility = Visibility.Visible;
        slIso.Visibility = Visibility.Visible;

        cbIsoAuto.IsChecked = isoSpeedControl.Auto;

        slIso.Minimum = isoSpeedControl.Min;
        slIso.Maximum = isoSpeedControl.Max;
        slIso.StepFrequency = isoSpeedControl.Step;

        slIso.ValueChanged -= slIso_ValueChanged;
        slIso.Value = isoSpeedControl.Value;
        slIso.ValueChanged += slIso_ValueChanged;
    }
    else
    {
        cbIsoAuto.Visibility = Visibility.Collapsed;
        slIso.Visibility = Visibility.Collapsed;
    }
}
```

In the **ValueChanged** event handler, get the current value of the control and the set the ISO speed value by calling **SetValueAsync**.

C#

```
private async void slIso_ValueChanged(object sender,
Microsoft.UI.Xaml.Controls.Primitives.RangeBaseValueChangedEventArgs e)
{
    var value = (sender as Slider).Value;
    await
m_mediaCapture.VideoDeviceController.IsoSpeedControl.SetValueAsync((uint)val
ue);
}
```

In the **CheckedChanged** event handler of the auto ISO speed checkbox, turn on automatic ISO speed adjustment by calling **SetAutoAsync**. Turn automatic ISO speed adjustment off by calling **SetValueAsync** and passing in the current value of the slider control.

C#

```
private async void cbIsoAuto_CheckedChanged(object sender, RoutedEventArgs
e)
{
    var autoIso = (sender as CheckBox).IsChecked == true;

    if (autoIso)
```

```
    {
        await
m_mediaCapture.VideoDeviceController.IsoSpeedControl.SetAutoAsync();
    }
    else
    {
        await
m_mediaCapture.VideoDeviceController.IsoSpeedControl.SetValueAsync((uint)slI
so.Value);
    }
}
```

Optical image stabilization

Optical image stabilization (OIS) stabilizes a captured video stream by mechanically manipulating the hardware capture device, which can provide a superior result than digital stabilization. On devices that don't support OIS, you can use the VideoStabilizationEffect to perform digital stabilization on your captured video. For more information, see Effects for video capture.

Determine if OIS is supported on the current device by checking the **OpticalImageStabilizationControl.Supported** property.

The OIS control supports three modes: on, off, and automatic, which means that the device dynamically determines if OIS would improve the media capture and, if so, enables OIS. To determine if a particular mode is supported on a device, check to see if the **OpticalImageStabilizationControl.SupportedModes** collection contains the desired mode.

Enable or disable OIS by setting the **OpticalImageStabilizationControl.Mode** to the desired mode.

C#

```
private void SetOpticalImageStabilizationMode(OpticalImageStabilizationMode
mode)
{
    if
(!m_mediaCapture.VideoDeviceController.OpticalImageStabilizationControl.Supp
orted)
    {
        tbStatus.Text = "Optical image stabilization not available";
        return;
    }

    var stabilizationModes =
m_mediaCapture.VideoDeviceController.OpticalImageStabilizationControl.Suppor
tedModes;
```

```
    if (!stabilizationModes.Contains(mode))
    {
        tbStatus.Text = "Optical image stabilization setting not supported";
        return;
    }

m_mediaCapture.VideoDeviceController.OpticalImageStabilizationControl.Mode =
mode;
}
```

Powerline frequency

Some camera devices support anti-flicker processing that depends on knowing the AC frequency of the powerlines in the current environment. Some devices support automatic determination of the powerline frequency, while others require that the frequency be set manually. The following code example shows how to determine powerline frequency support on the device and, if needed, how to set the frequency manually.

First, call the **VideoDeviceController** method **TryGetPowerlineFrequency**, passing in an output parameter of type **PowerlineFrequency**; if this call fails, the powerline frequency control is not supported on the current device. If the feature is supported, you can determine if automatic mode is available on the device by trying to set auto mode. Do this by calling **TrySetPowerlineFrequency** and passing in the value **Auto**. If the call succeeds, that means that your auto powerline frequency is supported. If the powerline frequency controller is supported on the device but automatic frequency detection is not, you can still manually set the frequency by using **TrySetPowerlineFrequency**. In this example, **MyCustomFrequencyLookup** is a custom method that you implement to determine the correct frequency for the device's current location.

C#

```
 PowerlineFrequency getFrequency;

 if (! m_mediaCapture.VideoDeviceController.TryGetPowerlineFrequency(out
getFrequency))
 {
     // Powerline frequency is not supported on this device.
     return;
 }

 if (!
m_mediaCapture.VideoDeviceController.TrySetPowerlineFrequency(PowerlineFrequ
ency.Auto))
 {
```

```
        // Set the frequency manually
        PowerlineFrequency setFrequency = MyCustomFrequencyLookup();
        if
(m_mediaCapture.VideoDeviceController.TrySetPowerlineFrequency(setFrequency)
)
        {
            System.Diagnostics.Debug.WriteLine(String.Format("Powerline
frequency manually set to {0}.", setFrequency));
        }
    }
```

White balance

The **WhiteBalanceControl** allows you to set the white balance used during photo or video capture.

This example uses a **ComboBox** control to select from built-in color temperature presets and a **Slider** control for manual white balance adjustment.

XML

```
<Slider Name="slWhiteBalance" ValueChanged="slWhiteBalance_ValueChanged"/>
<TextBlock Name="tbWhiteBalance" Text="{Binding
ElementName=slWhiteBalance,Path=Value}" Visibility="{Binding
ElementName=slWhiteBalance,Path=Visibility}"/>
<ComboBox Name="cbWhiteBalance"
SelectionChanged="cbWhiteBalance_SelectionChanged"/>
```

Check to see if the current capture device supports the **WhiteBalanceControl** by checking the **Supported** property. If the control is supported, you can show and enable the UI for this feature. Set the items of the combo box to the values of the **ColorTemperaturePreset** enumeration. And set the selected item to the current value of the **Preset** property.

For manual control, the white balance value must be within the range supported by the device and must be an increment of the supported step size. Get the supported values for the current device by checking the **Min**, **Max**, and **Step** properties, which are used to set the corresponding properties of the slider control. Before enabling manual control, check to make sure that the range between the minimum and maximum supported values is greater than the step size. If it is not, manual control is not supported on the current device.

Set the slider control's value to the current value of the **WhiteBalanceControl** after unregistering the **ValueChanged** event handler so that the event is not triggered when the value is set.

C#

```
            var whiteBalanceControl =
m_mediaCapture.VideoDeviceController.WhiteBalanceControl;

            if (whiteBalanceControl.Supported)
            {
                slWhiteBalance.Visibility = Visibility.Visible;
                cbWhiteBalance.Visibility = Visibility.Visible;

                if (cbWhiteBalance.ItemsSource == null)
                {
                    cbWhiteBalance.ItemsSource =
Enum.GetValues(typeof(ColorTemperaturePreset)).Cast<ColorTemperaturePreset>
();
                }

                cbWhiteBalance.SelectedItem = whiteBalanceControl.Preset;

                if (whiteBalanceControl.Max - whiteBalanceControl.Min >
whiteBalanceControl.Step)
                {

                    slWhiteBalance.Minimum = whiteBalanceControl.Min;
                    slWhiteBalance.Maximum = whiteBalanceControl.Max;
                    slWhiteBalance.StepFrequency = whiteBalanceControl.Step;

                    slWhiteBalance.ValueChanged -=
slWhiteBalance_ValueChanged;
                    slWhiteBalance.Value = whiteBalanceControl.Value;
                    slWhiteBalance.ValueChanged +=
slWhiteBalance_ValueChanged;
                }
                else
                {
                    slWhiteBalance.Visibility = Visibility.Collapsed;
                }
            }
            else
            {
                slWhiteBalance.Visibility = Visibility.Collapsed;
                cbWhiteBalance.Visibility = Visibility.Collapsed;
            }
```

In the SelectionChanged event handler of the color temperature preset combo box, get the currently selected preset and set the value of the control by calling SetPresetAsync. If the selected preset value is not **Manual**, disable the manual white balance slider.

C#

```
private async void cbWhiteBalance_SelectionChanged(object sender,
SelectionChangedEventArgs e)
```

```
{
    if(!m_isPreviewing)
    {
        // Do not set white balance values unless the preview stream is
running.
        return;
    }

    var selected = (ColorTemperaturePreset)cbWhiteBalance.SelectedItem;
    slWhiteBalance.IsEnabled = (selected == ColorTemperaturePreset.Manual);
    await
m_mediaCapture.VideoDeviceController.WhiteBalanceControl.SetPresetAsync(sele
cted);

}
```

In the **ValueChanged** event handler, get the current value of the control and the set the white balance value by calling **SetValueAsync**.

C#

```
private async void slWhiteBalance_ValueChanged(object sender,
Microsoft.UI.Xaml.Controls.Primitives.RangeBaseValueChangedEventArgs e)
{
    if (!m_isPreviewing)
    {
        // Do not set white balance values unless the preview stream is
running.
        return;
    }

    var value = (sender as Slider).Value;
    await
m_mediaCapture.VideoDeviceController.WhiteBalanceControl.SetValueAsync((uint
)value);
}
```

ⓘ Important

Adjusting the white balance is only supported while the preview stream is running. Check to make sure that the preview stream is running before setting the white balance value or preset.

ⓘ Important

The **ColorTemperaturePreset.Auto** preset value instructs the system to automatically adjust the white balance level. For some scenarios, such as capturing

a photo sequence where the white balance levels should be the same for each frame, you may want to lock the control to the current automatic value. To do this, call SetPresetAsync and specify the **Manual** preset and do not set a value on the control using SetValueAsync. This will cause the device to lock the current value. Do not attempt to read the current control value and then pass the returned value into **SetValueAsync** because this value is not guaranteed to be correct.

Zoom

The ZoomControl allows you to set the zoom level used during photo or video capture.

This example uses a Slider control to adjust the current zoom level. The following section shows how to adjust zoom based on a pinch gesture on the screen.

XML

```
<Slider Name="slZoom" Grid.Row="0" Orientation="Vertical"
HorizontalAlignment="Center" VerticalAlignment="Stretch"
ValueChanged="slZoom_ValueChanged"/>
<TextBlock Grid.Row="1" HorizontalAlignment="Center" Text="{Binding
ElementName=slZoom,Path=Value}"/>
<Button x:Name="bRegisterPinchGestureHandler" Content="Register pinch
gesture handler" Click="bRegisterPinchGestureHandler_Click"/>
```

Check to see if the current capture device supports the **ZoomControl** by checking the Supported property. If the control is supported, you can show and enable the UI for this feature.

The zoom level value must be within the range supported by the device and must be an increment of the supported step size. Get the supported values for the current device by checking the Min, Max, and Step properties, which are used to set the corresponding properties of the slider control.

Set the slider control's value to the current value of the **ZoomControl** after unregistering the ValueChanged event handler so that the event is not triggered when the value is set.

C#

```
var zoomControl = m_mediaCapture.VideoDeviceController.ZoomControl;

if (zoomControl.Supported)
{
    slZoom.Visibility = Visibility.Visible;

    slZoom.Minimum = zoomControl.Min;
```

```
    slZoom.Maximum = zoomControl.Max;
    slZoom.StepFrequency = zoomControl.Step;

    slZoom.ValueChanged -= slZoom_ValueChanged;
    slZoom.Value = zoomControl.Value;
    slZoom.ValueChanged += slZoom_ValueChanged;
}
else
{
    slZoom.Visibility = Visibility.Collapsed;
}
```

In the **ValueChanged** event handler, create a new instance of the ZoomSettings class, setting the Value property to the current value of the zoom slider control. If the SupportedModes property of the **ZoomControl** contains ZoomTransitionMode.Smooth, it means the device supports smooth transitions between zoom levels. Since this modes provides a better user experience, you will typically want to use this value for the Mode property of the **ZoomSettings** object.

Finally, change the current zoom settings by passing your **ZoomSettings** object into the Configure method of the **ZoomControl** object.

C#

```
private void slZoom_ValueChanged(object sender,
Microsoft.UI.Xaml.Controls.Primitives.RangeBaseValueChangedEventArgs e)
{
    var level = (float)slZoom.Value;
    var settings = new ZoomSettings { Value = level };

    var zoomControl = m_mediaCapture.VideoDeviceController.ZoomControl;
    if (zoomControl.SupportedModes.Contains(ZoomTransitionMode.Smooth))
    {
        settings.Mode = ZoomTransitionMode.Smooth;
    }
    else
    {
        settings.Mode = zoomControl.SupportedModes.First();
    }

    zoomControl.Configure(settings);
}
```

Smooth zoom using pinch gesture

As discussed in the previous section, on devices that support it, smooth zoom mode allows the capture device to smoothly transition between digital zoom levels, allowing the user to dynamically adjust the zoom level during the capture operation without

discrete and jarring transitions. This section describes how to adjust the zoom level in response to a pinch gesture.

First, determine if the digital zoom control is supported on the current device by checking the **ZoomControl.Supported** property. Next, determine if smooth zoom mode is available by checking the **ZoomControl.SupportedModes** to see if it contains the value **ZoomTransitionMode.Smooth**.

C#

```
private bool IsSmoothZoomSupported()
{
    if (!m_mediaCapture.VideoDeviceController.ZoomControl.Supported)
    {
        tbStatus.Text = "Digital zoom is not supported on this device.";
        return false;
    }

    var zoomModes =
m_mediaCapture.VideoDeviceController.ZoomControl.SupportedModes;

    if (!zoomModes.Contains(ZoomTransitionMode.Smooth))
    {
        tbStatus.Text = "Smooth zoom not supported";
        return false;
    }

    return true;
}
```

On a multi-touch enabled device, a typical scenario is to adjust the zoom factor based on a two-finger pinch gesture. Set the **ManipulationMode** property of the **CaptureElement** control to **ManipulationModes.Scale** to enable the pinch gesture. Then, register for the **ManipulationDelta** event which is raised when the pinch gesture changes size.

C#

```
private void RegisterPinchGestureHandler()
{
    if (!IsSmoothZoomSupported())
    {
        return;
    }

    // Enable pinch/zoom gesture for the MediaCaptureElement
    mpePreview.ManipulationMode = ManipulationModes.Scale;
    mpePreview.ManipulationDelta += MpePreview_ManipulationDelta;
}
```

In the handler for the **ManipulationDelta** event, update the zoom factor based on the change in the user's pinch gesture. The ManipulationDelta.Scale value represents the change in scale of the pinch gesture such that a small increase in the size of the pinch is a number slightly larger than 1.0 and a small decrease in the pinch size is a number slightly smaller than 1.0. In this example, the current value of the zoom control is multiplied by the scale delta.

Before setting the zoom factor, you must make sure that the value is not less than the minimum value supported by the device as indicated by the ZoomControl.Min property. Also, make sure that the value is less than or equal to the ZoomControl.Max value. Finally, you must make sure that the zoom factor is a multiple of the zoom step size supported by the device as indicated by the Step property. If your zoom factor does not meet these requirements, an exception will be thrown when you attempt to set the zoom level on the capture device.

Set the zoom level on the capture device by creating a new ZoomSettings object. Set the Mode property to ZoomTransitionMode.Smooth and then set the Value property to your desired zoom factor. Finally, call ZoomControl.Configure to set the new zoom value on the device. The device will smoothly transition to the new zoom value.

C#

```
private void MpePreview_ManipulationDelta(object sender,
ManipulationDeltaRoutedEventArgs e)
{
    var zoomControl = m_mediaCapture.VideoDeviceController.ZoomControl;

    // Example zoom factor calculation based on size of scale gesture
    var zoomFactor = zoomControl.Value * e.Delta.Scale;

    if (zoomFactor < zoomControl.Min) zoomFactor = zoomControl.Min;
    if (zoomFactor > zoomControl.Max) zoomFactor = zoomControl.Max;
    zoomFactor = zoomFactor - (zoomFactor % zoomControl.Step);

    var settings = new ZoomSettings();
    settings.Mode = ZoomTransitionMode.Smooth;
    settings.Value = zoomFactor;

    m_mediaCapture.VideoDeviceController.ZoomControl.Configure(settings);

}
```

Manual camera controls for video capture

Article • 01/16/2025

This article shows you how to use manual device controls to enable enhanced video capture scenarios, including HDR video and exposure priority.

The video device controls discussed in this article are all added to your app by using the same pattern. First, check to see if the control is supported on the current device on which your app is running. If the control is supported, set the desired mode for the control. Typically, if a particular control is unsupported on the current device, you should disable or hide the UI element that allows the user to enable the feature.

> **Note**
>
> This article builds on concepts and code discussed in Basic photo, video, and audio capture with MediaCapture, which describes the steps for implementing basic photo and video capture. We recommend that you familiarize yourself with the basic media capture pattern in that article before moving on to more advanced capture scenarios. The code in this article assumes that your app already has an instance of **MediaCapture** that has been properly initialized.

HDR video

The high dynamic range (HDR) video feature applies HDR processing to the video stream of the capture device. Determine if HDR video is supported by selecting the **HdrVideoControl.Supported** property.

The HDR video control supports three modes: on, off, and automatic, which means that the device dynamically determines if HDR video processing would improve the media capture and, if so, enables HDR video. To determine if a particular mode is supported on the current device, check to see if the **HdrVideoControl.SupportedModes** collection contains the desired mode.

Enable or disable HDR video processing by setting the **HdrVideoControl.Mode** to the desired mode. This control requires that the stream is at a stopped state before the mode is set, see KSPROPERTY_CAMERACONTROL_EXTENDED_VIDEOHDR.

```
C#
```

```
private void SetHdrVideoMode(HdrVideoMode mode)
{
    if (!m_mediaCapture.VideoDeviceController.HdrVideoControl.Supported)
    {
        tbStatus.Text = "HDR Video not available";
        return;
    }

    var hdrVideoModes =
m_mediaCapture.VideoDeviceController.HdrVideoControl.SupportedModes;

    if (!hdrVideoModes.Contains(mode))
    {
        tbStatus.Text = "HDR Video setting not supported";
        return;
    }

    m_mediaCapture.VideoDeviceController.HdrVideoControl.Mode = mode;
}
```

Exposure priority

The **ExposurePriorityVideoControl**, when enabled, evaluates the video frames from the capture device to determine if the video is capturing a low-light scene. If so, the control lowers the frame rate of the captured video in order to increase the exposure time for each frame and improve the visual quality of the captured video.

Determine if the exposure priority control is supported on the current device by checking the **ExposurePriorityVideoControl.Supported** property.

Enable or disable the exposure priority control by setting the **ExposurePriorityVideoControl.Enabled** to the desired mode.

C#

```
if
(!m_mediaCapture.VideoDeviceController.ExposurePriorityVideoControl.Supporte
d)
{
    tbStatus.Text = "Exposure priority not available";
    return;
}
m_mediaCapture.VideoDeviceController.ExposurePriorityVideoControl.Enabled =
true;
```

Temporal denoising

Starting with Windows 10, version 1803, you can enable temporal denoising for video on devices that support it. This feature fuses the image data from multiple adjacent frames in real time to produce video frames that have less visual noise.

The **VideoTemporalDenoisingControl** allows your app to determine if temporal denoising is supported on the current device, and if so, which denoising modes are supported. The available denoising modes are **Off**, **On**, and **Auto**. A device may not support all modes, but every device must support either **Auto** or **On** and **Off**.

The following example uses a simple UI to provide radio buttons allowing the user to switch between denoising modes.

XML

```
<StackPanel Orientation="Vertical" HorizontalAlignment="Right" >
    <StackPanel x:Name="spDenoise" Visibility="Collapsed">
        <TextBlock>Temporal Denoising</TextBlock>
        <RadioButton x:Name="rbDenoiseOff" Checked="rbDenoise_Checked"
            GroupName="Denoise Group" Content="Off"/>
        <RadioButton x:Name="rbDenoiseOn" Checked="rbDenoise_Checked"
            GroupName="Denoise Group" Content="On" Visibility="Collapsed"/>
        <RadioButton x:Name="rbDenoiseAuto" Checked="rbDenoise_Checked"
            GroupName="Denoise Group" Content="Auto"
Visibility="Collapsed"/>
    </StackPanel>
</StackPanel>
```

In the following method, the **VideoTemporalDenoisingControl.Supported** property is checked to see if temporal denoising is supported at all on the current device. If so, then we check to make sure that **Off** and **Auto** or **On** is supported, in which case we make our radio buttons visible. Next, the **Auto** and **On** buttons are made visible if those methods are supported.

C#

```
private void bUpdateDenoiseCapabilities_Click(object sender, RoutedEventArgs
e)
{
    if
(m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Supporte
d)
    {
         IReadOnlyList<VideoTemporalDenoisingMode> modes =
m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Supported
Modes;

if(modes.Contains(Windows.Media.Devices.VideoTemporalDenoisingMode.Off) &&

(modes.Contains(Windows.Media.Devices.VideoTemporalDenoisingMode.On) ||
```

```
modes.Contains(Windows.Media.Devices.VideoTemporalDenoisingMode.Auto)))
        {
            spDenoise.Visibility = Visibility.Visible;

            if
(modes.Contains(Windows.Media.Devices.VideoTemporalDenoisingMode.On))
            {
                rbDenoiseOn.Visibility = Visibility.Visible;
            }
            if
(modes.Contains(Windows.Media.Devices.VideoTemporalDenoisingMode.Auto))
            {
                rbDenoiseAuto.Visibility = Visibility.Visible;
            }
        }
    }
}
```

In the **Checked** event handler for the radio buttons, the name of the button is checked and the corresponding mode is set by setting the VideoTemporalDenoisingControl.Mode property.

C#

```
private void rbDenoise_Checked(object sender, RoutedEventArgs e)
{
    var button = sender as RadioButton;
    if(button.Name == "denoiseOffButton")
    {

m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Mode =
Windows.Media.Devices.VideoTemporalDenoisingMode.Off;
    }
    else if (button.Name == "denoiseOnButton")
    {

m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Mode =
Windows.Media.Devices.VideoTemporalDenoisingMode.On;
    }
    else if (button.Name == "denoiseAutoButton")
    {

m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Mode =
Windows.Media.Devices.VideoTemporalDenoisingMode.Auto;
    }
}
```

Disabling temporal denoising while processing frames

Video that has been processed using temporal denoising can be more pleasing to the human eye. However, because temporal denoising can impact image consistency and decrease the amount of details in the frame, apps that perform image processing on the frames, such as registration or optical character recognition, may want to programmatically disable denoising when image processing is enabled.

The following example determines which denoising modes are supported and stores this information in some class variables.

C#

```
private bool _isVideoTemporalDenoisingOffSupported = false;
private bool _isProcessing = false;
private Windows.Media.Devices.VideoTemporalDenoisingMode?
_videoDenoisingEnabledMode = null;
```

C#

```
private void ConfigureDenoiseForFrameProcessing()
{
    if
(m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Supporte
d)
    {
        // Query support for the VideoTemporalDenoising control Off mode
        _isVideoTemporalDenoisingOffSupported =
m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Supported
Modes.Contains(Windows.Media.Devices.VideoTemporalDenoisingMode.Off);

        // Query support for a mode that would enable VideoTemporalDenoising
(On or Auto) and toggle it if supported
        if
(m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Supporte
dModes.Contains(Windows.Media.Devices.VideoTemporalDenoisingMode.On))
        {
            _videoDenoisingEnabledMode =
Windows.Media.Devices.VideoTemporalDenoisingMode.On;

m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Mode =
(Windows.Media.Devices.VideoTemporalDenoisingMode)_videoDenoisingEnabledMode
;
        }
        else if
(m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Supporte
dModes.Contains(Windows.Media.Devices.VideoTemporalDenoisingMode.Auto))
        {
            _videoDenoisingEnabledMode =
Windows.Media.Devices.VideoTemporalDenoisingMode.Auto;

m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Mode =
(Windows.Media.Devices.VideoTemporalDenoisingMode)_videoDenoisingEnabledMode
```

```
;
            }
        }

    }
```

When the app enables frame processing, it sets the denoising mode to **Off** if that mode is supported so that the frame processing can use raw frames that have not been denoised.

C#

```
public void EnableFrameProcessing()
{
    // Toggle Off VideoTemporalDenoising
    if (_isVideoTemporalDenoisingOffSupported)
    {

m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Mode =
Windows.Media.Devices.VideoTemporalDenoisingMode.Off;
    }

    _isProcessing = true;
}
```

When the app disables frame processing, it sets the denoising mode to **On** or **Auto**, depending on which mode is supported.

C#

```
public void DisableFrameProcessing()
{
    _isProcessing = false;

    // If a VideoTemporalDenoising mode to enable VideoTemporalDenoising is
supported, toggle it
    if (_videoDenoisingEnabledMode != null)
    {

m_mediaCapture.VideoDeviceController.VideoTemporalDenoisingControl.Mode =
(Windows.Media.Devices.VideoTemporalDenoisingMode)_videoDenoisingEnabledMode
;
    }
}
```

For more information on obtaining video frames for image processing, see Process media frames with MediaFrameReader.

Effects for video capture

Article • 01/16/2025

This topic shows you how to apply effects to the camera preview and recording video streams and shows you how to use the video stabilization effect.

> **Note**
>
> This article builds on concepts and code discussed in Basic photo, video, and audio capture with MediaCapture, which describes the steps for implementing basic photo and video capture. We recommend that you familiarize yourself with the basic media capture pattern in that article before moving on to more advanced capture scenarios. The code in this article assumes that your app already has an instance of **MediaCapture** that has been properly initialized.

Adding and removing effects from the camera video stream

To capture or preview video from the device's camera, use the **MediaCapture** class as described in Basic photo, video, and audio capture with MediaCapture. After you have initialized the **MediaCapture** object, you can add one or more video effects to the preview or capture stream by calling **AddVideoEffectAsync**, passing in an **IVideoEffectDefinition** object representing the effect to be added, and a member of the **MediaStreamType** enumeration indicating whether the effect should be added to the camera's preview stream or the record stream.

> **Note**
>
> On some devices, the preview stream and the capture stream are the same, which means that if you specify **MediaStreamType.VideoPreview** or **MediaStreamType.VideoRecord** when you call **AddVideoEffectAsync**, the effect will be applied to both preview and record streams. You can determine whether the preview and record streams are the same on the current device by checking the VideoDeviceCharacteristic property of the MediaCaptureSettings for the **MediaCapture** object. If the value of this property is **VideoDeviceCharacteristic.AllStreamsIdentical** or **VideoDeviceCharacteristic.PreviewRecordStreamsIdentical**, then the streams are the same and any effect you apply to one will affect the other.

The following example adds an effect to both the camera preview and record streams. This example illustrates checking to see if the record and preview streams are the same.

C#

```
if (m_mediaCapture.MediaCaptureSettings.VideoDeviceCharacteristic ==
VideoDeviceCharacteristic.AllStreamsIdentical ||
    m_mediaCapture.MediaCaptureSettings.VideoDeviceCharacteristic ==
VideoDeviceCharacteristic.PreviewRecordStreamsIdentical)
{
    // This effect will modify both the preview and the record streams,
because they are the same stream.
    myRecordEffect = await
m_mediaCapture.AddVideoEffectAsync(myEffectDefinition,
MediaStreamType.VideoRecord);
}
else
{
    myRecordEffect = await
m_mediaCapture.AddVideoEffectAsync(myEffectDefinition,
MediaStreamType.VideoRecord);
    myPreviewEffect = await
m_mediaCapture.AddVideoEffectAsync(myEffectDefinition,
MediaStreamType.VideoPreview);
}
```

Note that **AddVideoEffectAsync** returns an object that implements **IMediaExtension** that represents the added video effect. Some effects allow you to change the effect settings by passing a **PropertySet** into the **SetProperties** method.

Starting with Windows 10, version 1607, you can also use the object returned by **AddVideoEffectAsync** to remove the effect from the video pipeline by passing it into **RemoveEffectAsync**. **RemoveEffectAsync** automatically determines whether the effect object parameter was added to the preview or record stream, so you don't need to specify the stream type when making the call.

C#

```
if (myRecordEffect != null)
{
    await m_mediaCapture.RemoveEffectAsync(myRecordEffect);
}
if (myPreviewEffect != null)
{
    await m_mediaCapture.RemoveEffectAsync(myPreviewEffect);
}
```

You can also remove all effects from the preview or capture stream by calling ClearEffectsAsync and specifying the stream for which all effects should be removed.

```
C#

await m_mediaCapture.ClearEffectsAsync(MediaStreamType.VideoPreview);
await m_mediaCapture.ClearEffectsAsync(MediaStreamType.VideoRecord);
```

Video stabilization effect

The video stabilization effect manipulates the frames of a video stream to minimize shaking caused by holding the capture device in your hand. Because this technique causes the pixels to be shifted right, left, up, and down, and because the effect can't know what the content just outside the video frame is, the stabilized video is cropped slightly from the original video. A utility function is provided to allow you to adjust your video encoding settings to optimally manage the cropping performed by the effect.

On devices that support it, Optical Image Stabilization (OIS) stabilizes video by mechanically manipulating the capture device and, therefore, does not need to crop the edges of the video frames. For more information, see Capture device controls for video capture.

Set up your app to use video stabilization

Declare a member variable to store the VideoStabilizationEffect object. As part of the effect implementation, you will modify the encoding properties that you use to encode the captured video. Declare two variables to store a backup copy of the initial input and output encoding properties so that you can restore them later when the effect is disabled. Finally, declare a member variable of type MediaEncodingProfile because this object will be accessed from multiple locations within your code.

```
C#

//
private VideoStabilizationEffect m_videoStabilizationEffect;
private VideoEncodingProperties m_inputPropertiesBackup;
private VideoEncodingProperties m_outputPropertiesBackup;
private MediaEncodingProfile m_encodingProfile;
```

For this scenario, you should assign the media encoding profile object to a member variable so that you can access it later.

```
```

C#

```
m_encodingProfile =
MediaEncodingProfile.CreateMp4(VideoEncodingQuality.Auto);
```

Initialize the video stabilization effect

After your **MediaCapture** object has been initialized, create a new instance of the **VideoStabilizationEffectDefinition** object. Call **MediaCapture.AddVideoEffectAsync** to add the effect to the video pipeline and retrieve an instance of the **VideoStabilizationEffect** class. Specify **MediaStreamType.VideoRecord** to indicate that the effect should be applied to the video record stream.

Register an event handler for the **EnabledChanged** event and call the helper method **SetUpVideoStabilizationRecommendationAsync**, both of which are discussed later in this article. Finally, set the **Enabled** property of the effect to true to enable the effect.

C#

```
// Create the effect definition
VideoStabilizationEffectDefinition stabilizerDefinition = new
VideoStabilizationEffectDefinition();

// Add the video stabilization effect to media capture
m_videoStabilizationEffect =
    (VideoStabilizationEffect)await
m_mediaCapture.AddVideoEffectAsync(stabilizerDefinition,
MediaStreamType.VideoRecord);

m_videoStabilizationEffect.EnabledChanged +=
VideoStabilizationEffect_EnabledChanged;

await SetUpVideoStabilizationRecommendationAsync();

m_videoStabilizationEffect.Enabled = true;
```

Use recommended encoding properties

As discussed earlier in this article, the technique that the video stabilization effect uses necessarily causes the stabilized video to be cropped slightly from the source video. Define the following helper function in your code in order to adjust the video encoding properties to optimally handle this limitation of the effect. This step is not required in order to use the video stabilization effect, but if you don't perform this step, the resulting video will be upscaled slightly and therefore have slightly lower visual fidelity.

Call **GetRecommendedStreamConfiguration** on your video stabilization effect instance, passing in the **VideoDeviceController** object, which informs the effect about your current input stream encoding properties, and your **MediaEncodingProfile** which lets the effect know your current output encoding properties. This method returns a **VideoStreamConfiguration** object containing new recommended input and output stream encoding properties.

The recommended input encoding properties are, if it is supported by the device, a higher resolution that the initial settings you provided so that there is minimal loss in resolution after the effect's cropping is applied.

Call **VideoDeviceController.SetMediaStreamPropertiesAsync** to set the new encoding properties. Before setting the new properties, use the member variable to store the initial encoding properties so that you can change the settings back when you disable the effect.

If the video stabilization effect must crop the output video, the recommended output encoding properties will be the size of the cropped video. This means that the output resolution will match the cropped video size. If you do not use the recommended output properties, the video will be scaled up to match the initial output size, which will result in a loss of visual fidelity.

Set the **Video** property of the **MediaEncodingProfile** object. Before setting the new properties, use the member variable to store the initial encoding properties so that you can change the settings back when you disable the effect.

C#

```
private async Task SetUpVideoStabilizationRecommendationAsync()
{

    // Get the recommendation from the effect based on our current input and
output configuration
    var recommendation =
m_videoStabilizationEffect.GetRecommendedStreamConfiguration(m_mediaCapture.
VideoDeviceController, m_encodingProfile.Video);

    // Handle the recommendation for the input into the effect, which can
contain a larger resolution than currently configured, so cropping is
minimized
    if (recommendation.InputProperties != null)
    {
        // Back up the current input properties from before VS was activated
        m_inputPropertiesBackup =
m_mediaCapture.VideoDeviceController.GetMediaStreamProperties(MediaStreamTyp
e.VideoRecord) as VideoEncodingProperties;

        // Set the recommendation from the effect (a resolution higher than
```

```
the current one to allow for cropping) on the input
        await
m_mediaCapture.VideoDeviceController.SetMediaStreamPropertiesAsync(MediaStre
amType.VideoRecord, recommendation.InputProperties);
        await
m_mediaCapture.VideoDeviceController.SetMediaStreamPropertiesAsync(MediaStre
amType.VideoPreview, recommendation.InputProperties);
    }

    // Handle the recommendations for the output from the effect
    if (recommendation.OutputProperties != null)
    {
        // Back up the current output properties from before VS was
activated
        m_outputPropertiesBackup = m_encodingProfile.Video;

        // Apply the recommended encoding profile for the output
        m_encodingProfile.Video = recommendation.OutputProperties;
    }
}
```

Handle the video stabilization effect being disabled

The system may automatically disable the video stabilization effect if the pixel throughput is too high for the effect to handle or if it detects that the effect is running slowly. If this occurs, the EnabledChanged event is raised. The **VideoStabilizationEffect** instance in the *sender* parameter indicates the new state of the effect, enabled or disabled. The VideoStabilizationEffectEnabledChangedEventArgs has a VideoStabilizationEffectEnabledChangedReason value indicating why the effect was enabled or disabled. Note that this event is also raised if you programmatically enable or disable the effect, in which case the reason will be **Programmatic**.

Typically, you would use this event to adjust your app's UI to indicate the current status of video stabilization.

C#

```
private async void
VideoStabilizationEffect_EnabledChanged(VideoStabilizationEffect sender,
VideoStabilizationEffectEnabledChangedEventArgs args)
{
    await Dispatcher.RunAsync(CoreDispatcherPriority.Normal, () =>
    {
        // Update your UI to reflect the change in status
        tbStatus.Text = "video stabilization status: " + sender.Enabled + ".
Reason: " + args.Reason;
    });
}
```

Clean up the video stabilization effect

To clean up the video stabilization effect, call **RemoveEffectAsync** to remove the effect from the video pipeline. If the member variables containing the initial encoding properties are not null, use them to restore the encoding properties. Finally, remove the **EnabledChanged** event handler and set the effect to null.

C#

```
// Clear all effects in the pipeline
await m_mediaCapture.RemoveEffectAsync(m_videoStabilizationEffect);

// If backed up settings (stream properties and encoding profile) exist,
restore them and clear the backups
if (m_inputPropertiesBackup != null)
{
    await
m_mediaCapture.VideoDeviceController.SetMediaStreamPropertiesAsync(MediaStre
amType.VideoRecord, m_inputPropertiesBackup);
    m_inputPropertiesBackup = null;
}

if (m_outputPropertiesBackup != null)
{
    m_encodingProfile.Video = m_outputPropertiesBackup;
    m_outputPropertiesBackup = null;
}

m_videoStabilizationEffect.EnabledChanged -=
VideoStabilizationEffect_EnabledChanged;

m_videoStabilizationEffect = null;
```

Scene analysis for MediaCapture

Article • 01/16/2025

This article describes how to use the **SceneAnalysisEffect** and the **FaceDetectionEffect** to analyze the content of the media capture preview stream.

Scene analysis effect

The **SceneAnalysisEffect** analyzes the video frames in the media capture preview stream and recommends processing options to improve the capture result. Currently, the effect supports detecting whether the capture would be improved by using High Dynamic Range (HDR) processing.

If the effect recommends using HDR, you can do this in the following ways:

- Use the **AdvancedPhotoCapture** class to capture photos using the Windows built-in HDR processing algorithm. For more information, see High dynamic range (HDR) and low-light photo capture.
- Use the **HdrVideoControl** to capture video using the Windows built-in HDR processing algorithm. For more information, see Capture device controls for video capture.
- Use the **VariablePhotoSequenceControl** to capture a sequence of frames that you can then composite using a custom HDR implementation. For more information, see Variable photo sequence.

Initialize the scene analysis effect and add it to the preview stream

Video effects are implemented using two APIs, an effect definition, which provides settings that the capture device needs to initialize the effect, and an effect instance, which can be used to control the effect. Since you may want to access the effect instance from multiple places within your code, you should typically declare a member variable to hold the object.

C#

```
private SceneAnalysisEffect m_sceneAnalysisEffect;
```

In your app, after you have initialized the **MediaCapture** object, create a new instance of SceneAnalysisEffectDefinition.

Register the effect with the capture device by calling AddVideoEffectAsync on your **MediaCapture** object, providing the **SceneAnalysisEffectDefinition** and specifying MediaStreamType.VideoPreview to indicate that the effect should be applied to the video preview stream, as opposed to the capture stream. **AddVideoEffectAsync** returns an instance of the added effect. Because this method can be used with multiple effect types, you must cast the returned instance to a SceneAnalysisEffect object.

To receive the results of the scene analysis, you must register a handler for the SceneAnalyzed event.

Currently, the scene analysis effect only includes the high dynamic range analyzer. Enable HDR analysis by setting the effect's HighDynamicRangeControl.Enabled to true.

        #endregion Face detection

    }
}
```

Implement the SceneAnalyzed event handler

The results of the scene analysis are returned in the **SceneAnalyzed** event handler. The SceneAnalyzedEventArgs object passed into the handler has a SceneAnalysisEffectFrame object which has a HighDynamicRangeOutput object. The Certainty property of the high dynamic range output provides a value between 0 and 1.0 where 0 indicates that HDR processing would not help improve the capture result and 1.0 indicates that HDR processing would help. You can decide the threshold point at which you want to use HDR or show the results to the user and let the user decide.

C#

```
private void SceneAnalysisEffect_SceneAnalyzed(SceneAnalysisEffect sender,
SceneAnalyzedEventArgs args)
{
    double hdrCertainty = args.ResultFrame.HighDynamicRange.Certainty;

    // Certainty value is between 0.0 and 1.0
    if (hdrCertainty > MyCertaintyCap)
    {
        DispatcherQueue.TryEnqueue(() =>
        {
            tbStatus.Text = "Enabling HDR capture is recommended.";
```

```
        });
    }
}
```

The **HighDynamicRangeOutput** object passed into the handler also has a **FrameControllers** property which contains suggested frame controllers for capturing a variable photo sequence for HDR processing. For more information, see Variable photo sequence.

Clean up the scene analysis effect

When your app is done capturing, before disposing of the **MediaCapture** object, you should disable the scene analysis effect by setting the effect's **HighDynamicRangeAnalyzer.Enabled** property to false and unregister your **SceneAnalyzed** event handler. Call **MediaCapture.ClearEffectsAsync**, specifying the video preview stream since that was the stream to which the effect was added. Finally, set your member variable to null.

C#

```
// Disable detection
m_sceneAnalysisEffect.HighDynamicRangeAnalyzer.Enabled = false;

m_sceneAnalysisEffect.SceneAnalyzed -= SceneAnalysisEffect_SceneAnalyzed;

// Remove the effect from the preview stream
await m_mediaCapture.ClearEffectsAsync(MediaStreamType.VideoPreview);

// Clear the member variable that held the effect instance
m_sceneAnalysisEffect = null;
```

Face detection effect

The **FaceDetectionEffect** identifies the location of faces within the media capture preview stream. The effect allows you to receive a notification whenever a face is detected in the preview stream and provides the bounding box for each detected face within the preview frame. On supported devices, the face detection effect also provides enhanced exposure and focus on the most important face in the scene.

Initialize the face detection effect and add it to the preview stream

Video effects are implemented using two APIs, an effect definition, which provides settings that the capture device needs to initialize the effect, and an effect instance, which can be used to control the effect. Since you may want to access the effect instance from multiple places within your code, you should typically declare a member variable to hold the object.

C#

```
FaceDetectionEffect m_faceDetectionEffect;
```

In your app, after you have initialized the **MediaCapture** object, create a new instance of FaceDetectionEffectDefinition. Set the DetectionMode property to prioritize faster face detection or more accurate face detection. Set SynchronousDetectionEnabled to specify that incoming frames are not delayed waiting for face detection to complete as this can result in a choppy preview experience.

Register the effect with the capture device by calling AddVideoEffectAsync on your **MediaCapture** object, providing the **FaceDetectionEffectDefinition** and specifying MediaStreamType.VideoPreview to indicate that the effect should be applied to the video preview stream, as opposed to the capture stream. **AddVideoEffectAsync** returns an instance of the added effect. Because this method can be used with multiple effect types, you must cast the returned instance to a FaceDetectionEffect object.

Enable or disable the effect by setting the FaceDetectionEffect.Enabled property. Adjust how often the effect analyzes frames by setting the FaceDetectionEffect.DesiredDetectionInterval property. Both of these properties can be adjusted while media capture is ongoing.

C#

```
// Create the definition, which will contain some initialization settings
var definition = new FaceDetectionEffectDefinition();

// To ensure preview smoothness, do not delay incoming samples
definition.SynchronousDetectionEnabled = false;

// In this scenario, choose detection speed over accuracy
definition.DetectionMode = FaceDetectionMode.HighPerformance;

// Add the effect to the preview stream
m_faceDetectionEffect = (FaceDetectionEffect)await
m_mediaCapture.AddVideoEffectAsync(definition,
MediaStreamType.VideoPreview);

// Choose the shortest interval between detection events
m_faceDetectionEffect.DesiredDetectionInterval =
```

```
TimeSpan.FromMilliseconds(33);

// Start detecting faces
m_faceDetectionEffect.Enabled = true;
```

Receive notifications when faces are detected

If you want to perform some action when faces are detected, such as drawing a box around detected faces in the video preview, you can register for the **FaceDetected** event.

C#

```
// Register for face detection events
m_faceDetectionEffect.FaceDetected += FaceDetectionEffect_FaceDetected;
```

In the handler for the event, you can get a list of all faces detected in a frame by accessing the **FaceDetectionEffectFrame.DetectedFaces** property of the **FaceDetectedEventArgs**. The **FaceBox** property is a **BitmapBounds** structure that describes the rectangle containing the detected face in units relative to the preview stream dimensions. To view sample code that transforms the preview stream coordinates into screen coordinates, see the face detection UWP sample.

C#

```
private void FaceDetectionEffect_FaceDetected(FaceDetectionEffect sender,
FaceDetectedEventArgs args)
{
    foreach (Windows.Media.FaceAnalysis.DetectedFace face in
args.ResultFrame.DetectedFaces)
    {
        BitmapBounds faceRect = face.FaceBox;

        // Draw a rectangle on the preview stream for each face
    }
}
```

Clean up the face detection effect

When your app is done capturing, before disposing of the **MediaCapture** object, you should disable the face detection effect with **FaceDetectionEffect.Enabled** and unregister your **FaceDetected** event handler if you previously registered one. Call **MediaCapture.ClearEffectsAsync**, specifying the video preview stream since that was the stream to which the effect was added. Finally, set your member variable to null.

C#

```
// Disable detection
m_faceDetectionEffect.Enabled = false;

// Unregister the event handler
m_faceDetectionEffect.FaceDetected -= FaceDetectionEffect_FaceDetected;

// Remove the effect from the preview stream
await m_mediaCapture.ClearEffectsAsync(MediaStreamType.VideoPreview);

// Clear the member variable that held the effect instance
m_faceDetectionEffect = null;
```

Check for focus and exposure support for detected faces

Not all devices have a capture device that can adjust its focus and exposure based on detected faces. Because face detection consumes device resources, you may only want to enable face detection on devices that can use the feature to enhance capture. To see if face-based capture optimization is available, get the **VideoDeviceController** for your initialized **MediaCapture** and then get the video device controller's **RegionsOfInterestControl**. Check to see if the **MaxRegions** supports at least one region. Then check to see if either **AutoExposureSupported** or **AutoFocusSupported** are true. If these conditions are met, then the device can take advantage of face detection to enhance capture.

C#

```
var regionsControl =
m_mediaCapture.VideoDeviceController.RegionsOfInterestControl;
bool faceDetectionFocusAndExposureSupported =
    regionsControl.MaxRegions > 0 &&
    (regionsControl.AutoExposureSupported ||
regionsControl.AutoFocusSupported);
```

Variable photo sequence

Article • 01/16/2025

This article shows you how to capture a variable photo sequence, which allows you to capture multiple frames of images in rapid succession and configure each frame to use different focus, flash, ISO, exposure, and exposure compensation settings. This feature enables scenarios like creating High Dynamic Range (HDR) images.

If you want to capture HDR images but don't want to implement your own processing algorithm, you can use the **AdvancedPhotoCapture** API to use the HDR capabilities built-in to Windows. For more information, see High dynamic range (HDR) and low-light photo capture.

> **Note**
>
> This article builds on concepts and code discussed in Basic photo, video, and audio capture with MediaCapture, which describes the steps for implementing basic photo and video capture. It is recommended that you familiarize yourself with the basic media capture pattern in that article before moving on to more advanced capture scenarios. The code in this article assumes that your app already has an instance of MediaCapture that has been properly initialized.

Set up your app to use variable photo sequence capture

Declare a member variable to store the **VariablePhotoSequenceCapture** object, which is used to initiate the photo sequence capture. Declare an array of **SoftwareBitmap** objects to store each captured image in the sequence. Also, declare an array to store the **CapturedFrameControlValues** object for each frame. This can be used by your image processing algorithm to determine what settings were used to capture each frame. Finally, declare an index that will be used to track which image in the sequence is currently being captured.

C#

```
VariablePhotoSequenceCapture m_photoSequenceCapture;
SoftwareBitmap[] m_images;
CapturedFrameControlValues[] m_frameControlValues;
int m_photoIndex;
```

Prepare the variable photo sequence capture

After you have initialized your MediaCapture, make sure that variable photo sequences are supported on the current device by getting an instance of the VariablePhotoSequenceController from the media capture's VideoDeviceController and checking the Supported property.

```
C#

var varPhotoSeqController =
m_mediaCapture.VideoDeviceController.VariablePhotoSequenceController;

if (!varPhotoSeqController.Supported)
{
    tbStatus.Text = "Variable Photo Sequence is not supported";
    return;
}
```

Get a FrameControlCapabilities object from the variable photo sequence controller. This object has a property for every setting that can be configured per frame of a photo sequence. These include:

- Exposure
- ExposureCompensation
- Flash
- Focus
- IsoSpeed
- PhotoConfirmation

This example will set a different exposure compensation value for each frame. To verify that exposure compensation is supported for photo sequences on the current device, check the Supported property of the FrameExposureCompensationCapabilities object accessed through the **ExposureCompensation** property.

```
C#

var frameCapabilities = varPhotoSeqController.FrameCapabilities;

if (!frameCapabilities.ExposureCompensation.Supported)
{
    tbStatus.Text = "EVCompenstaion is not supported in FrameController";
    return;
}
```

Create a new **FrameController** object for each frame you want to capture. This example captures three frames. Set the values for the controls you want to vary for each frame. Then, clear the **DesiredFrameControllers** collection of the **VariablePhotoSequenceController** and add each frame controller to the collection.

C#

```
var frame0 = new FrameController();
var frame1 = new FrameController();
var frame2 = new FrameController();

frame0.ExposureCompensationControl.Value = -1.0f;
frame1.ExposureCompensationControl.Value = 0.0f;
frame2.ExposureCompensationControl.Value = 1.0f;

varPhotoSeqController.DesiredFrameControllers.Clear();
varPhotoSeqController.DesiredFrameControllers.Add(frame0);
varPhotoSeqController.DesiredFrameControllers.Add(frame1);
varPhotoSeqController.DesiredFrameControllers.Add(frame2);
```

Create an **ImageEncodingProperties** object to set the encoding you want to use for the captured images. Call the static method **MediaCapture.PrepareVariablePhotoSequenceCaptureAsync**, passing in the encoding properties. This method returns a **VariablePhotoSequenceCapture** object. Finally, register event handlers for the **PhotoCaptured** and **Stopped** events.

C#

```
try
{
    var imageEncodingProperties = ImageEncodingProperties.CreateJpeg();

    m_photoSequenceCapture = await
m_mediaCapture.PrepareVariablePhotoSequenceCaptureAsync(imageEncodingPropert
ies);

    m_photoSequenceCapture.PhotoCaptured += OnPhotoCaptured;
    m_photoSequenceCapture.Stopped += OnStopped;
}
catch (Exception ex)
{
    tbStatus.Text = "Exception in PrepareVariablePhotoSequence: " +
ex.Message;
}
```

Start the variable photo sequence capture

To start the capture of the variable photo sequence, call VariablePhotoSequenceCapture.StartAsync. Be sure to initialize the arrays for storing the captured images and frame control values and set the current index to 0. Set your app's recording state variable and update your UI to disable starting another capture while this capture is in progress.

C#

```
private async void bStartVPS_Click(object sender, RoutedEventArgs e)
{
    m_images = new SoftwareBitmap[3];
    m_frameControlValues = new CapturedFrameControlValues[3];
    m_photoIndex = 0;
    m_isRecording = true;

    await m_photoSequenceCapture.StartAsync();
}
```

Receive the captured frames

The PhotoCaptured event is raised for each captured frame. Save the frame control values and captured image for the frame and then increment the current frame index. This example shows how to get a SoftwareBitmap representation of each frame. For more information on using **SoftwareBitmap**, see Imaging.

C#

```
void OnPhotoCaptured(VariablePhotoSequenceCapture s,
VariablePhotoCapturedEventArgs args)
{

    m_images[m_photoIndex] = args.Frame.SoftwareBitmap;
    m_frameControlValues[m_photoIndex] = args.CapturedFrameControlValues;
    m_photoIndex++;
}
```

Handle the completion of the variable photo sequence capture

The Stopped event is raised when all of the frames in the sequence have been captured. Update the recording state of your app and update your UI to allow the user to initiate new captures. At this point, you can pass the captured images and frame control values to your image processing code.

C#

```
void OnStopped(object s, object e)
{
    m_isRecording = false;
    MyPostProcessingFunction(m_images, m_frameControlValues, 3);
}
```

Update frame controllers

If you want to perform another variable photo sequence capture with different per frame settings, you don't need to completely reinitialize the **VariablePhotoSequenceCapture**. You can either clear the DesiredFrameControllers collection and add new frame controllers or you can modify the existing frame controller values. The following example checks the FrameFlashCapabilities object to verify that the current device supports flash and flash power for variable photo sequence frames. If so, each frame is updated to enable the flash at 100% power. The exposure compensation values that were previously set for each frame are still active.

C#

```
var varPhotoSeqController =
m_mediaCapture.VideoDeviceController.VariablePhotoSequenceController;

if (varPhotoSeqController.FrameCapabilities.Flash.Supported &&
    varPhotoSeqController.FrameCapabilities.Flash.PowerSupported)
{
    for (int i = 0; i < varPhotoSeqController.DesiredFrameControllers.Count;
i++)
    {
        varPhotoSeqController.DesiredFrameControllers[i].FlashControl.Mode =
FrameFlashMode.Enable;

varPhotoSeqController.DesiredFrameControllers[i].FlashControl.PowerPercent =
100;
    }
}
```

Clean up the variable photo sequence capture

When you are done capturing variable photo sequences or your app is suspending, clean up the variable photo sequence object by calling FinishAsync. Unregister the object's event handlers and set it to null.

C#

```
await m_photoSequenceCapture.FinishAsync();
m_photoSequenceCapture.PhotoCaptured -= OnPhotoCaptured;
m_photoSequenceCapture.Stopped -= OnStopped;
m_photoSequenceCapture = null;
```

Process media frames with MediaFrameReader

Article • 01/16/2025

This article shows you how to use a MediaFrameReader with MediaCapture to get media frames from one or more available sources, including color, depth, and infrared cameras, audio devices, or even custom frame sources such as those that produce skeletal tracking frames. This feature is designed to be used by apps that perform real-time processing of media frames, such as augmented reality and depth-aware camera apps.

If you are interested in simply capturing video or photos, such as a typical photography app, then you probably want to use one of the other capture techniques supported by MediaCapture. For a list of available media capture techniques and articles showing how to use them, see Camera.

> **Note**
>
> The features discussed in this article are only available starting with Windows 10, version 1607.

> **Note**
>
> There is a Universal Windows app sample that demonstrates using **MediaFrameReader** to display frames from different frame sources, including color, depth, and infrared cameras. For more information, see Camera frames sample.

> **Note**
>
> A new set of APIs for using **MediaFrameReader** with audio data were introduced in Windows 10, version 1803. For more information, see Process audio frames with MediaFrameReader.

Select frame sources and frame source groups

Many apps that process media frames need to get frames from multiple sources at once, such as a device's color and depth cameras. The MediaFrameSourceGroup object

represents a set of media frame sources that can be used simultaneously. Call the static method MediaFrameSourceGroup.FindAllAsync to get a list of all of the groups of frame sources supported by the current device.

C#

```
var frameSourceGroups = await MediaFrameSourceGroup.FindAllAsync();
```

You can also create a DeviceWatcher using DeviceInformation.CreateWatcher and the value returned from MediaFrameSourceGroup.GetDeviceSelector to receive notifications when the available frame source groups on the device changes, such as when an external camera is plugged in. For more information see Enumerate devices.

A MediaFrameSourceGroup has a collection of MediaFrameSourceInfo objects that describe the frame sources included in the group. After retrieving the frame source groups available on the device, you can select the group that exposes the frame sources you are interested in.

The following example shows the simplest way to select a frame source group. This code simply loops over all of the available groups and then loops over each item in the SourceInfos collection. Each **MediaFrameSourceInfo** is checked to see if it supports the features we are seeking. In this case, the MediaStreamType property is checked for the value VideoPreview, meaning the device provides a video preview stream, and the SourceKind property is checked for the value Color, indicating that the source provides color frames.

C#

```
var frameSourceGroups = await MediaFrameSourceGroup.FindAllAsync();

MediaFrameSourceGroup selectedGroup = null;
MediaFrameSourceInfo colorSourceInfo = null;

foreach (var sourceGroup in frameSourceGroups)
{
    foreach (var sourceInfo in sourceGroup.SourceInfos)
    {
        if (sourceInfo.MediaStreamType == MediaStreamType.VideoPreview
            && sourceInfo.SourceKind == MediaFrameSourceKind.Color)
        {
            colorSourceInfo = sourceInfo;
            break;
        }
    }
    if (colorSourceInfo != null)
    {
        selectedGroup = sourceGroup;
```

```
            break;
        }
    }
```

This method of identifying the desired frame source group and frame sources works for simple cases, but if you want to select frame sources based on more complex criteria, it can quickly become cumbersome. Another method is to use Linq syntax and anonymous objects to make the selection. The following example uses the **Select** extension method to transform the **MediaFrameSourceGroup** objects in the *frameSourceGroups* list into an anonymous object with two fields: *sourceGroup*, representing the group itself, and *colorSourceInfo*, which represents the color frame source in the group. The *colorSourceInfo* field is set to the result of **FirstOrDefault**, which selects the first object for which the provided predicate resolves to true. In this case, the predicate is true if the stream type is **VideoPreview**, the source kind is **Color**, and if the camera is on the front panel of the device.

From the list of anonymous objects returned from the query described above, the **Where** extension method is used to select only those objects where the *colorSourceInfo* field is not null. Finally, **FirstOrDefault** is called to select the first item in the list.

Now you can use the fields of the selected object to get references to the selected **MediaFrameSourceGroup** and the **MediaFrameSourceInfo** object representing the color camera. These will be used later to initialize the **MediaCapture** object and create a **MediaFrameReader** for the selected source. Finally, you should test to see if the source group is null, meaning the current device doesn't have your requested capture sources.

C#

```
var selectedGroupObjects = frameSourceGroups.Select(group =>
   new
   {
       sourceGroup = group,
       colorSourceInfo = group.SourceInfos.FirstOrDefault((sourceInfo) =>
       {
           // On Xbox/Kinect, omit the MediaStreamType and EnclosureLocation
tests
           return sourceInfo.MediaStreamType == MediaStreamType.VideoPreview
           && sourceInfo.SourceKind == MediaFrameSourceKind.Color
           && sourceInfo.DeviceInformation?.EnclosureLocation.Panel ==
Windows.Devices.Enumeration.Panel.Front;
       })

   }).Where(t => t.colorSourceInfo != null)
   .FirstOrDefault();

MediaFrameSourceGroup selectedGroup = selectedGroupObjects?.sourceGroup;
MediaFrameSourceInfo colorSourceInfo =
```

```
selectedGroupObjects?.colorSourceInfo;

if (selectedGroup == null)
{
    return;
}
```

The following example uses a similar technique as described above to select a source group that contains color, depth, and infrared cameras.

C#

```
var allGroups = await MediaFrameSourceGroup.FindAllAsync();
var eligibleGroups = allGroups.Select(g => new
{
    Group = g,

    // For each source kind, find the source which offers that kind of media
frame,
    // or null if there is no such source.
    SourceInfos = new MediaFrameSourceInfo[]
    {
        g.SourceInfos.FirstOrDefault(info => info.SourceKind ==
MediaFrameSourceKind.Color),
        g.SourceInfos.FirstOrDefault(info => info.SourceKind ==
MediaFrameSourceKind.Depth),
        g.SourceInfos.FirstOrDefault(info => info.SourceKind ==
MediaFrameSourceKind.Infrared),
    }
}).Where(g => g.SourceInfos.Any(info => info != null)).ToList();

if (eligibleGroups.Count == 0)
{
    System.Diagnostics.Debug.WriteLine("No source group with color, depth or
infrared found.");
    return;
}

var selectedGroupIndex = 0; // Select the first eligible group
MediaFrameSourceGroup selectedGroup =
eligibleGroups[selectedGroupIndex].Group;
MediaFrameSourceInfo colorSourceInfo =
eligibleGroups[selectedGroupIndex].SourceInfos[0];
MediaFrameSourceInfo infraredSourceInfo =
eligibleGroups[selectedGroupIndex].SourceInfos[1];
MediaFrameSourceInfo depthSourceInfo =
eligibleGroups[selectedGroupIndex].SourceInfos[2];
```

> ⓘ Note

Starting with Windows 10, version 1803, you can use the MediaCaptureVideoProfile class to select a media frame source with a set of desired capabilities. For more information, see the section **Use video profiles to select a frame source** later in this article.

Initialize the MediaCapture object to use the selected frame source group

The next step is to initialize the **MediaCapture** object to use the frame source group you selected in the previous step. Create an instance of the **MediaCapture** object by calling the constructor. Next, create a MediaCaptureInitializationSettings object that will be used to initialize the **MediaCapture** object. In this example, the following settings are used:

- SourceGroup - This tells the system which source group you will be using to get frames. Remember that the source group defines a set of media frame sources that can be used simultaneously.
- SharingMode - This tells the system whether you need exclusive control over the capture source devices. If you set this to ExclusiveControl, it means that you can change the settings of the capture device, such as the format of the frames it produces, but this means that if another app already has exclusive control, your app will fail when it tries to initialize the media capture device. If you set this to SharedReadOnly, you can receive frames from the frame sources even if they are in use by another app, but you can't change the settings for the devices.
- MemoryPreference - If you specify CPU, the system will use CPU memory which guarantees that when frames arrive, they will be available as SoftwareBitmap objects. If you specify Auto, the system will dynamically choose the optimal memory location to store frames. If the system chooses to use GPU memory, the media frames will arrive as an IDirect3DSurface object and not as a **SoftwareBitmap**.
- StreamingCaptureMode - Set this to Video to indicate that audio doesn't need to be streamed.

Call InitializeAsync to initialize the **MediaCapture** with your desired settings. Be sure to call this within a *try* block in case initialization fails.

C#

```
m_mediaCapture = new MediaCapture();

var settings = new MediaCaptureInitializationSettings()
```

```
{
    SourceGroup = selectedGroup,
    SharingMode = MediaCaptureSharingMode.ExclusiveControl,
    MemoryPreference = MediaCaptureMemoryPreference.Cpu,
    StreamingCaptureMode = StreamingCaptureMode.Video
};
try
{
    await m_mediaCapture.InitializeAsync(settings);
}
catch (Exception ex)
{
    System.Diagnostics.Debug.WriteLine("MediaCapture initialization failed:
" + ex.Message);
    return;
}
```

Set the preferred format for the frame source

To set the preferred format for a frame source, you need to get a **MediaFrameSource** object representing the source. You get this object by accessing the **Frames** dictionary of the initialized **MediaCapture** object, specifying the identifier of the frame source you want to use. This is why we saved the **MediaFrameSourceInfo** object when we were selecting a frame source group.

The **MediaFrameSource.SupportedFormats** property contains a list of **MediaFrameFormat** objects describing the supported formats for the frame source. In this example, a format is selected that has a width of 1080 pixels and can supply frames in 32-bit RGB format. The **FirstOrDefault** extension method selects the first entry in the list. If the selected format is null, then the requested format is not supported by the frame source. If the format is supported, you can request that the source use this format by calling **SetFormatAsync**.

C#

```
var colorFrameSource = m_mediaCapture.FrameSources[colorSourceInfo.Id];
var preferredFormat = colorFrameSource.SupportedFormats.Where(format =>
{
    return format.VideoFormat.Width >= 1080
    && format.Subtype == MediaEncodingSubtypes.Argb32;

}).FirstOrDefault();

if (preferredFormat == null)
{
    // Our desired format is not supported
    return;
}
```

```
await colorFrameSource.SetFormatAsync(preferredFormat);
```

Create a frame reader for the frame source

To receive frames for a media frame source, use a MediaFrameReader.

C#

```
MediaFrameReader m_mediaFrameReader;
```

Instantiate the frame reader by calling CreateFrameReaderAsync on your initialized **MediaCapture** object. The first argument to this method is the frame source from which you want to receive frames. You can create a separate frame reader for each frame source you want to use. The second argument tells the system the output format in which you want frames to arrive. This can save you from having to do your own conversions to frames as they arrive. Note that if you specify a format that is not supported by the frame source, an exception will be thrown, so be sure that this value is in the SupportedFormats collection.

After creating the frame reader, register a handler for the FrameArrived event which is raised whenever a new frame is available from the source.

Tell the system to start reading frames from the source by calling StartAsync.

C#

```
m_mediaFrameReader = await
m_mediaCapture.CreateFrameReaderAsync(colorFrameSource,
MediaEncodingSubtypes.Argb32);
m_mediaFrameReader.FrameArrived += ColorFrameReader_FrameArrived;
await m_mediaFrameReader.StartAsync();
```

Handle the frame arrived event

The MediaFrameReader.FrameArrived event is raised whenever a new frame is available. You can choose to process every frame that arrives or only use frames when you need them. Because the frame reader raises the event on its own thread, you may need to implement some synchronization logic to make sure that you aren't attempting to access the same data from multiple threads. This section shows you how to synchronize drawing color frames to an image control in a XAML page. This scenario

addresses the additional synchronization constraint that requires all updates to XAML controls be performed on the UI thread.

The first step in displaying frames in XAML is to create an Image control.

```
XML

<Image x:Name="iFrameReaderImageControl" MaxWidth="300" MaxHeight="200"/>
```

In your code behind page, declare a class member variable of type **SoftwareBitmap** which will be used as a back buffer that all incoming images will be copied to. Note that the image data itself isn't copied, just the object references. Also, declare a boolean to track whether our UI operation is currently running.

```
C#

private SoftwareBitmap backBuffer;
private bool taskRunning = false;
```

Because the frames will arrive as **SoftwareBitmap** objects, you need to create a SoftwareBitmapSource object which allows you to use a **SoftwareBitmap** as the source for a XAML **Control**. You should set the image source somewhere in your code before you start the frame reader.

```
C#

iFrameReaderImageControl.Source = new SoftwareBitmapSource();
```

Now it's time to implement the **FrameArrived** event handler. When the handler is called, the *sender* parameter contains a reference to the **MediaFrameReader** object which raised the event. Call TryAcquireLatestFrame on this object to attempt to get the latest frame. As the name implies, **TryAcquireLatestFrame** may not succeed in returning a frame. So, when you access the VideoMediaFrame and then SoftwareBitmap properties, be sure to test for null. In this example the null conditional operator ? is used to access the **SoftwareBitmap** and then the retrieved object is checked for null.

The **Image** control can only display images in BRGA8 format with either pre-multiplied or no alpha. If the arriving frame is not in that format, the static method Convert is used to convert the software bitmap to the correct format.

Next, the Interlocked.Exchange method is used to swap the reference of to arriving bitmap with the backbuffer bitmap. This method swaps these references in an atomic

operation that is thread-safe. After swapping, the old backbuffer image, now in the *softwareBitmap* variable is disposed of to clean up its resources.

Next, the CoreDispatcher associated with the **Image** element is used to create a task that will run on the UI thread by calling RunAsync. Because the asynchronous tasks will be performed within the task, the lambda expression passed to **RunAsync** is declared with the *async* keyword.

Within the task, the *_taskRunning* variable is checked to make sure that only one instance of the task is running at a time. If the task isn't already running, *_taskRunning* is set to true to prevent the task from running again. In a *while* loop, **Interlocked.Exchange** is called to copy from the backbuffer into a temporary **SoftwareBitmap** until the backbuffer image is null. For each time the temporary bitmap is populated, the **Source** property of the **Image** is cast to a **SoftwareBitmapSource**, and then SetBitmapAsync is called to set the source of the image.

Finally, the *_taskRunning* variable is set back to false so that the task can be run again the next time the handler is called.

> **Note**
>
> If you access the SoftwareBitmap or Direct3DSurface objects provided by the VideoMediaFrame property of a MediaFrameReference, the system creates a strong reference to these objects, which means that they will not be disposed when you call Dispose on the containing **MediaFrameReference**. You must explicitly call the **Dispose** method of the **SoftwareBitmap** or **Direct3DSurface** directly for the objects to be immediately disposed. Otherwise, the garbage collector will eventually free the memory for these objects, but you can't know when this will occur, and if the number of allocated bitmaps or surfaces exceeds the maximum amount allowed by the system, the flow of new frames will stop. You can copy retrieved frames, using the SoftwareBitmap.Copy method for example, and then release the original frames to overcome this limitation. Also, if you create the **MediaFrameReader** using the overload CreateFrameReaderAsync(Windows.Media.Capture.Frames.MediaFrameSource inputSource, System.String outputSubtype, Windows.Graphics.Imaging.BitmapSize outputSize) or CreateFrameReaderAsync(Windows.Media.Capture.Frames.MediaFrameSource inputSource, System.String outputSubtype), the frames returned are copies of the original frame data and so they do not cause frame acquisition to halt when they are retained.

C#

```
private void ColorFrameReader_FrameArrived(MediaFrameReader sender,
MediaFrameArrivedEventArgs args)
{
    var mediaFrameReference = sender.TryAcquireLatestFrame();
    var videoMediaFrame = mediaFrameReference?.VideoMediaFrame;
    var softwareBitmap = videoMediaFrame?.SoftwareBitmap;

    if (softwareBitmap != null)
    {
        if (softwareBitmap.BitmapPixelFormat !=
Windows.Graphics.Imaging.BitmapPixelFormat.Bgra8 ||
            softwareBitmap.BitmapAlphaMode !=
Windows.Graphics.Imaging.BitmapAlphaMode.Premultiplied)
        {
            softwareBitmap = SoftwareBitmap.Convert(softwareBitmap,
BitmapPixelFormat.Bgra8, BitmapAlphaMode.Premultiplied);
        }

        // Swap the processed frame to _backBuffer and dispose of the unused
image.
        softwareBitmap = Interlocked.Exchange(ref backBuffer,
softwareBitmap);
        softwareBitmap?.Dispose();

        // Changes to XAML ImageElement must happen on UI thread through
Dispatcher
        var task = iFrameReaderImageControl.DispatcherQueue.TryEnqueue(
            async () =>
            {
                // Don't let two copies of this task run at the same time.
                if (taskRunning)
                {
                    return;
                }
                taskRunning = true;

                // Keep draining frames from the backbuffer until the
backbuffer is empty.
                SoftwareBitmap latestBitmap;
                while ((latestBitmap = Interlocked.Exchange(ref backBuffer,
null)) != null)
                {
                    var imageSource =
(SoftwareBitmapSource)iFrameReaderImageControl.Source;
                    await imageSource.SetBitmapAsync(latestBitmap);
                    latestBitmap.Dispose();
                }

                taskRunning = false;
            });
    }
```

```
    if (mediaFrameReference != null)
    {
        mediaFrameReference.Dispose();
    }
}
```

Cleanup resources

When you are done reading frames, be sure to stop the media frame reader by calling StopAsync, unregistering the **FrameArrived** handler, and disposing of the **MediaCapture** object.

C#

```
await m_mediaFrameReader.StopAsync();
m_mediaFrameReader.FrameArrived -= ColorFrameReader_FrameArrived;
m_mediaCapture.Dispose();
m_mediaCapture = null;
```

For more information about cleaning up media capture objects when your application is suspended, see **Show the camera preview in a WinUI 3 app**.

The FrameRenderer helper class

This section provides the full code listing for a provides a helper class that makes it easy to display the frames from color, infrared, and depth sources in your app. Typically, you will want to do something more with depth and infrared data than just display it to the screen, but this helper class is a helpful tool for demonstrating the frame reader feature and for debugging your own frame reader implementation. The code in this section is adapted from the Camera frames sample.

The **FrameRenderer** helper class implements the following methods.

- **FrameRenderer** constructor - The constructor initializes the helper class to use the XAML **Image** element you pass in for displaying media frames.
- **ProcessFrame** - This method displays a media frame, represented by a **MediaFrameReference**, in the **Image** element you passed into the constructor. You should typically call this method from your **FrameArrived** event handler, passing in the frame returned by **TryAcquireLatestFrame**.
- **ConvertToDisplayableImage** - This methods checks the format of the media frame and, if necessary, converts it to a displayable format. For color images, this means making sure that the color format is BGRA8 and that the bitmap alpha mode is

premultiplied. For depth or infrared frames, each scanline is processed to convert the depth or infrared values to a psuedocolor gradient, using the **PsuedoColorHelper** class that is also included in the sample and listed below.

> **Note**
>
> In order to do pixel manipulation on **SoftwareBitmap** images, you must access a native memory buffer. To do this, you must use the IMemoryBufferByteAccess COM interface included in the code listing below and you must update your project properties to allow compilation of unsafe code. For more information, see Create, edit, and save bitmap images.

C#

```
[GeneratedComInterface]
[Guid("5B0D3235-4DBA-4D44-865E-8F1D0E4FD04D")]
[InterfaceType(ComInterfaceType.InterfaceIsIUnknown)]
unsafe partial interface IMemoryBufferByteAccess
{
    void GetBuffer(out byte* buffer, out uint capacity);
}
```

C#

```
class FrameRenderer
{
    private Image m_imageElement;
    private SoftwareBitmap m_backBuffer;
    private bool _taskRunning = false;

    public FrameRenderer(Image imageElement)
    {
        m_imageElement = imageElement;
        m_imageElement.Source = new SoftwareBitmapSource();
    }

    // Processes a MediaFrameReference and displays it in a XAML image
control
    public void ProcessFrame(MediaFrameReference frame)
    {
        var softwareBitmap =
FrameRenderer.ConvertToDisplayableImage(frame?.VideoMediaFrame);
        if (softwareBitmap != null)
        {
            // Swap the processed frame to m_backBuffer and trigger UI
thread to render it
            softwareBitmap = Interlocked.Exchange(ref m_backBuffer,
softwareBitmap);
```

```
            // UI thread always reset m_backBuffer before using it.  Unused
bitmap should be disposed.
            softwareBitmap?.Dispose();

            // Changes to xaml ImageElement must happen in UI thread through
Dispatcher
            var task = m_imageElement.DispatcherQueue.TryEnqueue(
                async () =>
                {
                    // Don't let two copies of this task run at the same
time.
                    if (_taskRunning)
                    {
                        return;
                    }
                    _taskRunning = true;

                    // Keep draining frames from the backbuffer until the
backbuffer is empty.
                    SoftwareBitmap latestBitmap;
                    while ((latestBitmap = Interlocked.Exchange(ref
m_backBuffer, null)) != null)
                    {
                        var imageSource =
(SoftwareBitmapSource)m_imageElement.Source;
                        await imageSource.SetBitmapAsync(latestBitmap);
                        latestBitmap.Dispose();
                    }

                    _taskRunning = false;
                });
        }
    }

    // Function delegate that transforms a scanline from an input image to
an output image.
    private unsafe delegate void TransformScanline(int pixelWidth, byte*
inputRowBytes, byte* outputRowBytes);
    /// <summary>
    /// Determines the subtype to request from the MediaFrameReader that
will result in
    /// a frame that can be rendered by ConvertToDisplayableImage.
    /// </summary>
    /// <returns>Subtype string to request, or null if subtype is not
renderable.</returns>

    public static string GetSubtypeForFrameReader(MediaFrameSourceKind kind,
MediaFrameFormat format)
    {
        // Note that media encoding subtypes may differ in case.
        // https://docs.microsoft.com/en-
us/uwp/api/Windows.Media.MediaProperties.MediaEncodingSubtypes
```

```
        string subtype = format.Subtype;
        switch (kind)
        {
            // For color sources, we accept anything and request that it be
converted to Bgra8.
            case MediaFrameSourceKind.Color:
                return
Windows.Media.MediaProperties.MediaEncodingSubtypes.Bgra8;

            // The only depth format we can render is D16.
            case MediaFrameSourceKind.Depth:
                return String.Equals(subtype,
Windows.Media.MediaProperties.MediaEncodingSubtypes.D16,
StringComparison.OrdinalIgnoreCase) ? subtype : null;

            // The only infrared formats we can render are L8 and L16.

Use MultiSourceMediaFrameReader to get time-correlated frames from multiple sources

Starting with Windows 10, version 1607, you can use **MultiSourceMediaFrameReader** to receive time-corellated frames from multiple sources. This API makes it easier to do processing that requires frames from multiple sources that were taken in close temporal proximity, such as using the **DepthCorrelatedCoordinateMapper** class. One limitation of using this new method is that frame-arrived events are only raised at the rate of the slowest capture source. Extra frames from faster sources will be dropped. Also, because the system expects frames to arrive from different sources at different rates, it does not automatically recognize if a source has stopped generating frames altogether. The example code in this section shows how to use an event to create your own timeout logic that gets invoked if correlated frames don't arrive within an app-defined time limit.

The steps for using **MultiSourceMediaFrameReader** are similar to the steps for using **MediaFrameReader** described previously in this article. This example will use a color source and a depth source. Declare some string variables to store the media frame source IDs that will be used to select frames from each source. Next, declare a **ManualResetEventSlim**, a **CancellationTokenSource**, and an **EventHandler** that will be used to implement timeout logic for the example.

C#

```
private MultiSourceMediaFrameReader m_multiFrameReader = null;
private string m_colorSourceId = null;
private string m_depthSourceId = null;

private readonly ManualResetEventSlim m_frameReceived = new
ManualResetEventSlim(false);
private readonly CancellationTokenSource m_tokenSource = new
CancellationTokenSource();
public event EventHandler CorrelationFailed;
```

Using the techniques described previously in this article, query for a MediaFrameSourceGroup that includes the color and depth sources required for this example scenario. After selecting the desired frame source group, get the MediaFrameSourceInfo for each frame source.

C#

```
var allGroups = await MediaFrameSourceGroup.FindAllAsync();
var eligibleGroups = allGroups.Select(g => new
{
    Group = g,

    // For each source kind, find the source which offers that kind of media
frame,
    // or null if there is no such source.
    SourceInfos = new MediaFrameSourceInfo[]
    {
        g.SourceInfos.FirstOrDefault(info => info.SourceKind ==
MediaFrameSourceKind.Color),
        g.SourceInfos.FirstOrDefault(info => info.SourceKind ==
MediaFrameSourceKind.Depth)
    }
}).Where(g => g.SourceInfos.Any(info => info != null)).ToList();

if (eligibleGroups.Count == 0)
{
    System.Diagnostics.Debug.WriteLine("No source group with color, depth or
infrared found.");
    return;
}

var selectedGroupIndex = 0; // Select the first eligible group
MediaFrameSourceGroup selectedGroup =
eligibleGroups[selectedGroupIndex].Group;
MediaFrameSourceInfo colorSourceInfo =
eligibleGroups[selectedGroupIndex].SourceInfos[0];
MediaFrameSourceInfo depthSourceInfo =
eligibleGroups[selectedGroupIndex].SourceInfos[1];
```

Create and initialize a **MediaCapture** object, passing the selected frame source group in the initialization settings.

```
C#

m_mediaCapture = new MediaCapture();

var settings = new MediaCaptureInitializationSettings()
{
    SourceGroup = selectedGroup,
    SharingMode = MediaCaptureSharingMode.ExclusiveControl,
    MemoryPreference = MediaCaptureMemoryPreference.Cpu,
    StreamingCaptureMode = StreamingCaptureMode.Video
};

await m_mediaCapture.InitializeAsync(settings);
```

After initializing the **MediaCapture** object, retrieve MediaFrameSource objects for the color and depth cameras. Store the ID for each source so that you can select the arriving frame for the corresponding source.

```
C#

MediaFrameSource colorSource =
    m_mediaCapture.FrameSources.Values.FirstOrDefault(
        s => s.Info.SourceKind == MediaFrameSourceKind.Color);

MediaFrameSource depthSource =
    m_mediaCapture.FrameSources.Values.FirstOrDefault(
        s => s.Info.SourceKind == MediaFrameSourceKind.Depth);

if (colorSource == null || depthSource == null)
{
    System.Diagnostics.Debug.WriteLine("MediaCapture doesn't have the Color
and Depth streams");
    return;
}

m_colorSourceId = colorSource.Info.Id;
m_depthSourceId = depthSource.Info.Id;
```

Create and initialize the **MultiSourceMediaFrameReader** by calling CreateMultiSourceFrameReaderAsync and passing an array of frame sources that the reader will use. Register an event handler for the FrameArrived event. This example creates an instance the **FrameRenderer** helper class, described previously in this article, to render frames to an **Image** control. Start the frame reader by calling StartAsync.

Register an event handler for the **CorellationFailed** event declared earlier in the example. We will signal this event if one of the media frame sources being used stops producing frames. Finally, call Task.Run to call the timeout helper method, **NotifyAboutCorrelationFailure**, on a separate thread. The implementation of this method is shown later in this article.

```
C#
```

```
m_multiFrameReader = await m_mediaCapture.CreateMultiSourceFrameReaderAsync(
    new[] { colorSource, depthSource });

m_multiFrameReader.FrameArrived += MultiFrameReader_FrameArrived;

m_frameRenderer = new FrameRenderer(iFrameReaderImageControl);

MultiSourceMediaFrameReaderStartStatus startStatus =
    await m_multiFrameReader.StartAsync();

if (startStatus != MultiSourceMediaFrameReaderStartStatus.Success)
{
    throw new InvalidOperationException(
        "Unable to start reader: " + startStatus);
}

this.CorrelationFailed += MainWindow_CorrelationFailed;
Task.Run(() => NotifyAboutCorrelationFailure(m_tokenSource.Token));
```

The **FrameArrived** event is raised whenever a new frame is available from all of the media frame sources that are managed by the **MultiSourceMediaFrameReader**. This means that the event will be raised on the cadence of the slowest media source. If one source produces multiple frames in the time that a slower source produces one frame, the extra frames from the fast source will be dropped.

Get the MultiSourceMediaFrameReference associated with the event by calling TryAcquireLatestFrame. Get the **MediaFrameReference** associated with each media frame source by calling TryGetFrameReferenceBySourceId, passing in the ID strings stored when the frame reader was initialized.

Call the Set method of the **ManualResetEventSlim** object to signal that frames have arrived. We will check this event in the **NotifyCorrelationFailure** method that is running in a separate thread.

Finally, perform any processing on the time-correlated media frames. This example simply displays the frame from the depth source.

```
C#
```

```
private void MultiFrameReader_FrameArrived(MultiSourceMediaFrameReader
sender, MultiSourceMediaFrameArrivedEventArgs args)
{
    using (MultiSourceMediaFrameReference muxedFrame =
        sender.TryAcquireLatestFrame())
    using (MediaFrameReference colorFrame =
        muxedFrame.TryGetFrameReferenceBySourceId(m_colorSourceId))
    using (MediaFrameReference depthFrame =
        muxedFrame.TryGetFrameReferenceBySourceId(m_depthSourceId))
    {
        // Notify the listener thread that the frame has been received.
        m_frameReceived.Set();
        m_frameRenderer.ProcessFrame(depthFrame);
    }
}
```

The **NotifyCorrelationFailure** helper method was run on a separate thread after the frame reader was started. In this method, check to see if the frame received event has been signaled. Remember, in the **FrameArrived** handler, we set this event whenever a set of correlated frames arrive. If the event hasn't been signaled for some app-defined period of time - 5 seconds is a reasonable value - and the task wasn't cancelled using the **CancellationToken**, then it's likely that one of the media frame sources has stopped reading frames. In this case you typically want to shut down the frame reader, so raise the app-defined **CorrelationFailed** event. In the handler for this event you can stop the frame reader and clean up it's associated resources as shown previously in this article.

C#

```
private void NotifyAboutCorrelationFailure(CancellationToken token)
{
    // If in 5 seconds the token is not cancelled and frame event is not
signaled,
    // correlation is most likely failed.
    if (WaitHandle.WaitAny(new[] { token.WaitHandle,
m_frameReceived.WaitHandle }, 5000)
            == WaitHandle.WaitTimeout)
    {
        CorrelationFailed?.Invoke(this, EventArgs.Empty);
    }
}
```

C#

```
private async void MainWindow_CorrelationFailed(object sender, EventArgs e)
{
    await m_multiFrameReader.StopAsync();
    m_multiFrameReader.FrameArrived -= MultiFrameReader_FrameArrived;
    m_mediaCapture.Dispose();
```

```
    m_mediaCapture = null;
}
```

Use buffered frame acquisition mode to preserve the sequence of acquired frames

Starting with Windows 10, version 1709, you can set the **AcquisitionMode** property of a **MediaFrameReader** or **MultiSourceMediaFrameReader** to **Buffered** to preserve the sequence of frames passed into your app from the frame source.

```
C#

m_mediaFrameReader.AcquisitionMode =
MediaFrameReaderAcquisitionMode.Buffered;
```

In the default acquisition mode, **Realtime**, if multiple frames are acquired from the source while your app is still handling the **FrameArrived** event for a previous frame, the system will send your app the most recently acquired frame and drop additional frames waiting in the buffer. This provides your app with the most recent available frame at all times. This is typically the most useful mode for realtime computer vision applications.

In **Buffered** acquisition mode, the system will keep all frames in the buffer and provide them to your app through the **FrameArrived** event in the order received. Note that in this mode, when system's buffer for frames is filled, the system will stop acquiring new frames until your app completes the **FrameArrived** event for previous frames, freeing up more space in the buffer.

Use MediaSource to display frames in a MediaPlayerElement

Starting with Windows, version 1709, you can display frames acquired from a **MediaFrameReader** directly in a **MediaPlayerElement** control in your XAML page. This is achieved by using the **MediaSource.CreateFromMediaFrameSource** to create **MediaSource** object that can be used directly by a **MediaPlayer** associated with a **MediaPlayerElement**. For detailed information on working with **MediaPlayer** and **MediaPlayerElement**, see Play audio and video with MediaPlayer.

The following code examples show you a simple implementation that displays the frames from a front-facing and back-facing camera simultaneously in a XAML page.

First, add two **MediaPlayerElement** controls to your XAML page.

XML

```
<MediaPlayerElement x:Name="mediaPlayerElement1" Width="320" Height="240"/>
```

XML

```
<MediaPlayerElement x:Name="mediaPlayerElement2" Width="320" Height="240"/>
```

Next, using the techniques shown in previous sections in this article, select a **MediaFrameSourceGroup** that contains **MediaFrameSourceInfo** objects for color cameras on the front panel and back panel. Note that the **MediaPlayer** does not automatically convert frames from non-color formats, such as a depth or infrared data, into color data. Using other sensor types may produce unexpected results.

C#

```
var allGroups = await MediaFrameSourceGroup.FindAllAsync();
var eligibleGroups = allGroups.Select(g => new
{
    Group = g,

    // For each source kind, find the source which offers that kind of media
frame,
    // or null if there is no such source.
    SourceInfos = new MediaFrameSourceInfo[]
    {
        g.SourceInfos.FirstOrDefault(info =>
info.DeviceInformation?.EnclosureLocation.Panel ==
Windows.Devices.Enumeration.Panel.Front
            && info.SourceKind == MediaFrameSourceKind.Color),
        g.SourceInfos.FirstOrDefault(info =>
info.DeviceInformation?.EnclosureLocation.Panel ==
Windows.Devices.Enumeration.Panel.Back
            && info.SourceKind == MediaFrameSourceKind.Color)
    }
}).Where(g => g.SourceInfos.Any(info => info != null)).ToList();

if (eligibleGroups.Count == 0)
{
    System.Diagnostics.Debug.WriteLine("No source group with front and back-
facing camera found.");
    return;
}

var selectedGroupIndex = 0; // Select the first eligible group
MediaFrameSourceGroup selectedGroup =
eligibleGroups[selectedGroupIndex].Group;
```

```
MediaFrameSourceInfo frontSourceInfo = selectedGroup.SourceInfos[0];
MediaFrameSourceInfo backSourceInfo = selectedGroup.SourceInfos[1];
```

Initialize the **MediaCapture** object to use the selected **MediaFrameSourceGroup**.

C#

```
m_mediaCapture = new MediaCapture();

var settings = new MediaCaptureInitializationSettings()
{
    SourceGroup = selectedGroup,
    SharingMode = MediaCaptureSharingMode.ExclusiveControl,
    MemoryPreference = MediaCaptureMemoryPreference.Cpu,
    StreamingCaptureMode = StreamingCaptureMode.Video
};
try
{
    await m_mediaCapture.InitializeAsync(settings);
}
catch (Exception ex)
{
    System.Diagnostics.Debug.WriteLine("MediaCapture initialization failed:
" + ex.Message);
    return;
}
```

Finally, call MediaSource.CreateFromMediaFrameSource to create a **MediaSource** for each frame source by using the Id property of the associated **MediaFrameSourceInfo** object to select one of the frame sources in the **MediaCapture** object's FrameSources collection. Initialize a new **MediaPlayer** object and assign it to a **MediaPlayerElement** by calling SetMediaPlayer. Then set the Source property to the newly created **MediaSource** object.

C#

```
var frameMediaSource1 =
MediaSource.CreateFromMediaFrameSource(m_mediaCapture.FrameSources[frontSour
ceInfo.Id]);
mediaPlayerElement1.SetMediaPlayer(new
Windows.Media.Playback.MediaPlayer());
mediaPlayerElement1.MediaPlayer.Source = frameMediaSource1;
mediaPlayerElement1.AutoPlay = true;

var frameMediaSource2 =
MediaSource.CreateFromMediaFrameSource(m_mediaCapture.FrameSources[backSourc
eInfo.Id]);
mediaPlayerElement2.SetMediaPlayer(new
Windows.Media.Playback.MediaPlayer());
```

```
mediaPlayerElement2.MediaPlayer.Source = frameMediaSource2;
mediaPlayerElement2.AutoPlay = true;
```

Use video profiles to select a frame source

A camera profile, represented by a MediaCaptureVideoProfile object, represents a set of capabilities that a particular capture device provides, such as frame rates, resolutions, or advanced features like HDR capture. A capture device may support multiple profiles, allowing you to select the one that is optimized for your capture scenario. Starting with Windows 10, version 1803, you can use **MediaCaptureVideoProfile** to select a media frame source with particular capabilities before initializing the **MediaCapture** object. The following example code looks for a video profile that supports HDR with Wide Color Gamut (WCG) and returns a **MediaCaptureInitializationSettings** object that can be used to initialize the **MediaCapture** to use the selected device and profile.

First, call MediaFrameSourceGroup.FindAllAsync to get a list of all media frame source groups available on the current device. Loop through each source group and call MediaCapture.FindKnownVideoProfiles to get a list of all of the video profiles for the current source group that support the specified profile, in this case HDR with WCG photo. If a profile that meets the criteria is found, create a new **MediaCaptureInitializationSettings** object and set the **VideoProfile** to the select profile and the **VideoDeviceId** to the **Id** property of the current media frame source group.

C#

```
IReadOnlyList<MediaFrameSourceGroup> sourceGroups = await
MediaFrameSourceGroup.FindAllAsync();
MediaCaptureInitializationSettings settings = null;

foreach (MediaFrameSourceGroup sourceGroup in sourceGroups)
{
    // Find a device that support AdvancedColorPhoto
    IReadOnlyList<MediaCaptureVideoProfile> profileList =
MediaCapture.FindKnownVideoProfiles(
                                    sourceGroup.Id,
                                    KnownVideoProfile.HdrWithWcgPhoto);

    if (profileList.Count > 0)
    {
        settings = new MediaCaptureInitializationSettings();
        settings.VideoProfile = profileList[0];
        settings.VideoDeviceId = sourceGroup.Id;
        break;
    }
}
```

For more information on using camera profiles, see Camera profiles.

Process audio frames with MediaFrameReader

Article • 01/16/2025

This article shows you how to use a MediaFrameReader with MediaCapture to get audio data from a media frame source. To learn about using a **MediaFrameReader** to get image data, such as from a color, infrared, or depth camera, see Process media frames with MediaFrameReader. That article provides a general overview of the frame reader usage pattern and discusses some additional features of the **MediaFrameReader** class, such as using **MediaFrameSourceGroup** to retrieve frames from multiple sources at the same time.

> **Note**
>
> The features discussed in this article are only available starting with Windows 10, version 1803.

Setting up your project

The process for acquiring audio frames is largely the same as acquiring other types of media frames. As with any app that uses **MediaCapture**, you must declare that your app uses the *webcam* capability before attempting to access any camera device. If your app will capture from an audio device, you should also declare the *microphone* device capability.

Select frame sources and frame source groups

The first step in capturing audio frames is to initialize a MediaFrameSource representing the source of the audio data, such as a microphone or other audio capture device. To do this, you must create a new instance of the MediaCapture object. For this example, the only initialization setting for the **MediaCapture** is setting the StreamingCaptureMode to indicate that we want to stream audio from the capture device.

After calling MediaCapture.InitializeAsync, you can get the list of accessible media frame sources with the FrameSources property. This example selects all frame sources where the MediaFrameSourceInfo describing the frame source has a MediaStreamType of **Audio**, indicating that the media source produces audio data.

If the query returns one or more frame sources, you can check the CurrentFormat property to see if the source supports the audio format you desire - in this example, float audio data. Check the AudioEncodingProperties to make sure the audio encoding you desire is supported by the source.

C#

```
m_mediaCapture = new MediaCapture();
MediaCaptureInitializationSettings settings = new
MediaCaptureInitializationSettings()
{
    StreamingCaptureMode = StreamingCaptureMode.Audio,
};
await m_mediaCapture.InitializeAsync(settings);

var audioFrameSources = m_mediaCapture.FrameSources.Where(x =>
x.Value.Info.MediaStreamType == MediaStreamType.Audio);

if (audioFrameSources.Count() == 0)
{
    Debug.WriteLine("No audio frame source was found.");
    return;
}

MediaFrameSource frameSource = audioFrameSources.FirstOrDefault().Value;

MediaFrameFormat format = frameSource.CurrentFormat;
if (format.Subtype != MediaEncodingSubtypes.Float)
{
    return;
}

if (format.AudioEncodingProperties.ChannelCount != 2
    || format.AudioEncodingProperties.SampleRate != 48000)
{
    return;
}
```

Create and Start the MediaFrameReader

Get a new instance of **MediaFrameReader** by calling MediaCapture.CreateFrameReaderAsync, passing the **MediaFrameSource** object you selected in the previous step. By default, audio frames are obtained in buffered mode, making it less likely that frames will be dropped, although this can still occur if you are not processing audio frames fast enough and fill up the system's alloted memory buffer.

Register a handler for the MediaFrameReader.FrameArrived event, which is raised by the system when a new frame of audio data is available. Call StartAsync to begin the

acquisition of audio frames. If the frame reader fails to start, the status value returned from the call will have a value other than Success.

C#

```
m_mediaFrameReader = await
m_mediaCapture.CreateFrameReaderAsync(frameSource);

// Optionally set acquisition mode. Buffered is the default mode for audio.
m_mediaFrameReader.AcquisitionMode =
MediaFrameReaderAcquisitionMode.Buffered;

m_mediaFrameReader.FrameArrived += MediaFrameReader_AudioFrameArrived;

var status = await m_mediaFrameReader.StartAsync();

if (status != MediaFrameReaderStartStatus.Success)
{
    Debug.WriteLine("The MediaFrameReader couldn't start.");
}
```

In the **FrameArrived** event handler, call TryAcquireLatestFrame on the **MediaFrameReader** object passed as the sender to the handler to attempt to retrieve a reference to the latest media frame. Note that this object can be null, so you should always check before using the object. The typs of media frame wrapped in the **MediaFrameReference** returned from **TryAcquireLatestFrame** depends on what type of frame source or sources you configured the frame reader to acquire. Since the frame reader in this example was set up to acquire audio frames, it gets the underlying frame using the AudioMediaFrame property.

This **ProcessAudioFrame** helper method in the example below shows how to get an AudioFrame which provides information such as the timestamp of the frame and whether it is discontinuous from the **AudioMediaFrame** object. To read or process the audio sample data, you will need to get the AudioBuffer object from the **AudioMediaFrame** object, create an IMemoryBufferReference, and then call the COM method **IMemoryBufferByteAccess::GetBuffer** to retrieve the data. See the note below the code listing for more information on accessing native buffers.

The format of the data depends on the frame source. In this example, when selecting a media frame source, we explicitly made certain that the selected frame source used two channels of float data. The rest of the example code shows how to determine the duration and sample count for the audio data in the frame.

C#

```
private void MediaFrameReader_AudioFrameArrived(MediaFrameReader sender,
MediaFrameArrivedEventArgs args)
{
    using (MediaFrameReference reference = sender.TryAcquireLatestFrame())
    {
        if (reference != null)
        {
            ProcessAudioFrame(reference.AudioMediaFrame);
        }
    }
}
unsafe private void ProcessAudioFrame(AudioMediaFrame audioMediaFrame)
{

    using (AudioFrame audioFrame = audioMediaFrame.GetAudioFrame())
    using (AudioBuffer buffer =
audioFrame.LockBuffer(AudioBufferAccessMode.Read))
    using (IMemoryBufferReference reference = buffer.CreateReference())
    {
        byte* dataInBytes;
        uint capacityInBytes;
        float* dataInFloat;

        var memoryBuffer = reference.As<IMemoryBufferByteAccess>();
        memoryBuffer.GetBuffer(out dataInBytes, out capacityInBytes);

        // The requested format was float
        dataInFloat = (float*)dataInBytes;

        // Get the number of samples by multiplying the duration by sampling
rate:
        // duration [s] x sampling rate [samples/s] = # samples

        // Duration can be gotten off the frame reference OR the audioFrame
        TimeSpan duration = audioMediaFrame.FrameReference.Duration;

        // frameDurMs is in milliseconds, while SampleRate is given per
second.
        uint frameDurMs = (uint)duration.TotalMilliseconds;
        uint sampleRate =
audioMediaFrame.AudioEncodingProperties.SampleRate;
        uint sampleCount = (frameDurMs * sampleRate) / 1000;

    }
}
```

> **Note**
>
> In order to do operate on the audio data, you must access a native memory buffer. To do this, you must use the **IMemoryBufferByteAccess** COM interface by

including the code listing below. Operations on the native buffer must be performed in a method that uses the **unsafe** keyword. You also need to check the box to allow unsafe code in the **Build** tab of the **Project -> Properties** dialog.

C#

```
[ComImport]
[Guid("5B0D3235-4DBA-4D44-865E-8F1D0E4FD04D")]
[InterfaceType(ComInterfaceType.InterfaceIsIUnknown)]
unsafe interface IMemoryBufferByteAccess
{
    void GetBuffer(out byte* buffer, out uint capacity);
}
```

Additional information on using MediaFrameReader with audio data

You can retrieve the **AudioDeviceController** associated with the audio frame source by accessing the **MediaFrameSource.Controller** property. This object can be used to get or set the stream properties of the capture device or to control the capture level. The following example mutes the audio device so that frames continue to be acquired by the frame reader, but all samples have value of 0.

C#

```
m_audioDeviceController.Muted = true;
```

You can use an **AudioFrame** object to pass audio data captured by a media frame source into an **AudioGraph**. Pass the frame into the **AddFrame** method of an **AudioFrameInputNode**. For more information on using audio graphs to capture, process, and mix audio signals, see Audio graphs.

Detect and respond to audio level changes by the system

Article • 01/16/2025

Learn how to detect and respond to audio level changes by the system. Starting with Windows 10, version 1803, your app can detect when the system lowers or mutes the audio level of your app's audio capture and audio render streams. For example, the system may mute your app's streams when it goes into the background.

To learn about capturing audio using the **MediaCapture** class, see Basic photo, video, and audio capture with MediaCapture. For information about audio playback using MediaPlayer, see TBD.

The **AudioStateMonitor** class allows you to register to receive an event when the system modifies the volume of an audio capture or render stream. Get an instance of **AudioStateMonitor** for monitoring audio capture streams by calling **CreateForCaptureMonitoring**. Get an instance for monitoring audio render streams by calling **CreateForRenderMonitoring**. Register a handler for the **SoundLevelChanged** event of each monitor to be notified when the audio for the corresponding stream category is changed by the system.

C#

```
AudioStateMonitor captureAudioStateMonitor;
AudioStateMonitor renderAudioStateMonitor;
```

C#

```
captureAudioStateMonitor = AudioStateMonitor.CreateForCaptureMonitoring();
captureAudioStateMonitor.SoundLevelChanged +=
CaptureAudioStateMonitor_SoundLevelChanged;

renderAudioStateMonitor = AudioStateMonitor.CreateForRenderMonitoring();
renderAudioStateMonitor.SoundLevelChanged +=
RenderAudioStateMonitor_SoundLevelChanged;
```

In the **SoundLevelChanged** handler for the capture stream, you can check the **SoundLevel** property of the **AudioStateMonitor** sender to determine the new sound level. Note that a capture stream should never be lowered, or "ducked", by the system. It should only ever be muted or switched back to full volume. If the audio stream is muted, you can stop a capture in progress. If the audio stream is restored to full volume, you can start capturing again.

C#

```
bool isCapturingAudio = false;
bool capturingStoppedForAudioState = false;

private void CaptureAudioStateMonitor_SoundLevelChanged(AudioStateMonitor
sender, object args)
{
    switch (sender.SoundLevel)
    {
        case SoundLevel.Full:
            if (capturingStoppedForAudioState)
            {
                MyStartAudioCapture();
                capturingStoppedForAudioState = false;
            }
            break;
        case SoundLevel.Muted:
            if (isCapturingAudio)
            {
                MyStopAudioCapture();
                capturingStoppedForAudioState = true;
            }
            break;
        case SoundLevel.Low:
            // This should never happen for capture
            Debug.WriteLine("Unexpected audio state.");
            break;
    }
}
```

The following code example illustrates an implementation of the **SoundLevelChanged** handler for audio rendering. Depending on your app scenario, and the type of content you are playing, you may want to pause audio playback when the sound level is ducked.

C#

```
bool contentIsPodcast;
private void RenderAudioStateMonitor_SoundLevelChanged(AudioStateMonitor
sender, object args)
{
    if ((sender.SoundLevel == SoundLevel.Full) ||
        (sender.SoundLevel == SoundLevel.Low && !contentIsPodcast))
    {
        m_mediaPlayer.Play();
    }
    else if ((sender.SoundLevel == SoundLevel.Muted) ||
         (sender.SoundLevel == SoundLevel.Low && contentIsPodcast))
    {
        // Pause playback if we re muted or if we re playing a podcast and
are ducked
        m_mediaPlayer.Pause();
```

```
    }
}
```

Launch the camera settings page

Article • 01/16/2025

Windows defines a set of URIs that allow apps to launch the Windows Settings app and display a particular settings page. This article explains how to launch the Windows Settings app directly to the camera settings page and, optionally, navigate directly to the settings for a particular camera on the device. For more information, see Launch the Windows Settings app.

The camera settings URL

Starting with Windows 11, Build 22000, the URI `ms-settings:camera` launches the Windows Settings app and navigates to the camera settings page. Note that in previous versions of Windows, this same URI would launch the default camera application. In addition to the general camera settings page, you can append the query string parameter `cameraId` set to the symbolic link name, in escaped URI format, to launch directly to the settings page for the associated camera.

In the following example, the DeviceInformation class is used to retrieve the symbolic link name for the first video capture device on the current machine, if one exists. Next, LaunchUriAsync is called to launch the Windows Settings app. The `ms-settings:camera` Uri specifies that the camera settings page should be shown. The optional query string parameter `cameraId` is set to the symbolic link name for the camera, escaped with a call to Url.EscapeDataString, to specify that the settings for the associated camera should be shown.

C#

```
private async void bLaunchCameraSettings_Click(object sender,
RoutedEventArgs e)
{
    var captureDevices = await
DeviceInformation.FindAllAsync(DeviceClass.VideoCapture);
    if (captureDevices.Count() > 0)
    {
        var cameraSymbolicLink = captureDevices.First().Id;
        bool result = await Windows.System.Launcher.LaunchUriAsync(new
Uri("ms-settings:camera?cameraId=" +
Uri.EscapeDataString(cameraSymbolicLink)));
    }
}
```

Handle the Windows camera privacy setting

Article • 01/16/2025

Windows allows users to grant or deny access to the device's camera in the Windows Settings app, under **Privacy & Security -> Camera**. Camera access can be disabled for the entire device, for all unpackaged apps, or for individual packaged apps. This article describes the best practices for checking whether your app has access to the camera and handling the case where access is denied by the user.

Check for access before initializing the camera

For packaged apps, you should check to see if your app has camera access before initializing the camera. Use the AppCapability class to determine if your app has access.

C#

C#

```
bool cameraCapabilityAccess = false;
private void CheckCameraAccessStatus()
{
    var status = AppCapability.Create("Webcam").CheckAccess();

    if (status == AppCapabilityAccessStatus.Allowed)
    {
        cameraCapabilityAccess = true;
        cameraButton.IsEnabled = true;
    }
    else
    {
        cameraCapabilityAccess = false;
        cameraButton.IsEnabled = false;
    }
}
```

Handle the access denied error

The Windows camera capture APIs will return the error **E_ACCESSDENIED** when apps attempt to access the camera capture device if the user has disabled camera in the camera privacy Settings page. Apps should check for this error when initializing the

capture device. If the initialization fails with this error, it is recommended that you direct the user to the camera privacy Settings page and potentially enable access for your app. The camera privacy Settings page can be launched using the URI `ms-settings:privacy-webcam`.

The following example illustrates how to check for E_ACCESSDENIED when calling MediaCapture.InitializeAsync.

C#

```
C#

try
{
    await
mediaCapture.InitializeAsync(mediaCaptureInitializationSettings);
}
catch (System.UnauthorizedAccessException ex)
{
    // E_ACCESSDENIED, 0x80070005 in hexadecimal, -2147024891 in decimal
    if (ex.HResult == -2147024891)
    {
        StatusTextBlock.Text = "Access to the camera has been denied." +
            "Click the Settings button to check the camera privacy
settings";
    }

    return;
}
...
// Launch the camera privacy Settings page
private async void LaunchSettingsButton_Click(object sender,
RoutedEventArgs e)
{
    bool result = await Windows.System.Launcher.LaunchUriAsync(new
Uri("ms-settings:privacy-webcam"));
}
```

The following example illustrates handling the E_ACCESSDENIED error returned from IMFActivate::ActivateObject when initializing an IMFMediaSource for a capture device.

```
C++

IMFMediaSource* pSource = NULL;
IMFAttributes* pAttributes = NULL;
IMFActivate** ppDevices = NULL;

// Create an attribute store to specify the enumeration parameters.
```

```
HRESULT hr = MFCreateAttributes(&pAttributes, 1);
if (FAILED(hr))
{
    goto done;
}

// Source type: video capture devices
hr = pAttributes->SetGUID(
    MF_DEVSOURCE_ATTRIBUTE_SOURCE_TYPE,
    MF_DEVSOURCE_ATTRIBUTE_SOURCE_TYPE_VIDCAP_GUID
);
if (FAILED(hr))
{
    goto done;
}

// Enumerate devices.
UINT32 count;
hr = MFEnumDeviceSources(pAttributes, &ppDevices, &count);
if (FAILED(hr))
{
    goto done;
}

if (count == 0)
{
    hr = E_FAIL;
    goto done;
}

// Create the media source object.
hr = ppDevices[0]->ActivateObject(IID_PPV_ARGS(&pSource));
if (FAILED(hr))
{
    if (hr == E_ACCESSDENIED)
    {
        int response = MessageBox(hWnd, L"Access to the camera was denied.
Open the camera privacy settings?", L"Error", MB_YESNO);
        if (response == IDYES)
        {
            ShellExecute(NULL, L"open", L"ms-settings:privacy-webcam", L"",
L".", SW_SHOWDEFAULT);
        }
    }
    goto done;
}
```

Implement fallback behavior

Apps should implement the previous steps to alert the user detect and alert the user that camera access is restricted due to privacy settings and to direct the user to the

camera privacy Settings page to allow them to update their settings. After these steps, the app should retry camera initialization to see if access has been granted. If the user declines to update their settings to allow your app to access to the camera, consider providing alternative functionality. For example, you could disable camera features, switch to a different mode, or display a placeholder image in place of the camera preview.

Connect to remote cameras

Article • 01/16/2025

This article shows you how to connect to one or more remote cameras and get a **MediaFrameSourceGroup** object that allows you to read frames from each camera. For more information on reading frames from a media source, see Process media frames with MediaFrameReader. For more information on pairing with devices, see Pair devices.

> **Note**
>
> The features discussed in this article are available starting with Windows 10, version 1903.

Create a DeviceWatcher class to watch for available remote cameras

The **DeviceWatcher** class monitors the devices available to your app and notifies your app when devices are added or removed. Get an instance of **DeviceWatcher** by calling **DeviceInformation.CreateWatcher**, passing in an Advanced Query Syntax (AQS) string that identifies the type of devices you want to monitor. The AQS string specifying network camera devices is the following:

syntax

```
@"System.Devices.InterfaceClassGuid:=""{B8238652-B500-41EB-B4F3-
4234F7F5AE99}"" AND
System.Devices.InterfaceEnabled:=System.StructuredQueryType.Boolean#True"
```

> **Note**
>
> The helper method MediaFrameSourceGroup.GetDeviceSelector returns an AQS string that will monitor locally-connected and remote network cameras. To monitor only network cameras, you should use the AQS string shown above.

When you start the returned **DeviceWatcher** by calling the **Start** method, it will raise the **Added** event for every network camera that is currently available. Until you stop the watcher by calling **Stop**, the **Added** event will be raised when new network camera

devices become available and the Removed event will be raised when a camera device becomes unavailable.

The event args passed into the **Added** and **Removed** event handlers are a DeviceInformation or a DeviceInformationUpdate object, respectively. Each of these objects has an **Id** property that is the identifier for the network camera for which the event was fired. Pass this ID into the MediaFrameSourceGroup.FromIdAsync method to get a MediaFrameSourceGroup object that you can use to retrieve frames from the camera.

Remote camera pairing helper class

The following example shows a helper class that uses a **DeviceWatcher** to create and update an **ObservableCollection** of **MediaFrameSourceGroup** objects to support data binding to the list of cameras. Typical apps would wrap the **MediaFrameSourceGroup** in a custom model class. Note that the helper class maintains a reference to the app's DispatcherQueue and updates the collection of cameras on the UI thread.

Also, this example handles the DeviceWatcher.Updated event in addition to the **Added** and **Removed** events. In the **Updated** handler, the associated remote camera device is removed from and then added back to the collection.

C#

```
class RemoteCameraPairingHelper : IDisposable
{
    private DispatcherQueue _dispatcherQueue;
    private DeviceWatcher _watcher;
    private ObservableCollection<MediaFrameSourceGroup>
_remoteCameraCollection;

    public RemoteCameraPairingHelper(DispatcherQueue uiDispatcherQueue)
    {
        _dispatcherQueue = uiDispatcherQueue;
        _remoteCameraCollection = new
ObservableCollection<MediaFrameSourceGroup>();
        var remoteCameraAqs = @"System.Devices.InterfaceClassGuid:=""
{B8238652-B500-41EB-B4F3-4234F7F5AE99}"" AND
System.Devices.InterfaceEnabled:=System.StructuredQueryType.Boolean#True";
        _watcher = DeviceInformation.CreateWatcher(remoteCameraAqs);
        _watcher.Added += Watcher_Added;
        _watcher.Removed += Watcher_Removed;
        _watcher.Updated += Watcher_Updated;
        _watcher.Start();
    }
    public void Dispose()
    {
        _watcher.Stop();
```

```
        _watcher.Updated -= Watcher_Updated;
        _watcher.Removed -= Watcher_Removed;
        _watcher.Added -= Watcher_Added;
    }
    public IReadOnlyList<MediaFrameSourceGroup> FrameSourceGroups
    {

        get { return _remoteCameraCollection; }
    }
    private async void Watcher_Updated(DeviceWatcher sender,
DeviceInformationUpdate args)
    {
        await RemoveDevice(args.Id);
        await AddDeviceAsync(args.Id);
    }
    private async void Watcher_Removed(DeviceWatcher sender,
DeviceInformationUpdate args)
    {
        await RemoveDevice(args.Id);
    }
    private async void Watcher_Added(DeviceWatcher sender, DeviceInformation
args)
    {
        await AddDeviceAsync(args.Id);
    }
    private async Task AddDeviceAsync(string id)
    {
        var group = await MediaFrameSourceGroup.FromIdAsync(id);
        if (group != null)
        {
            _dispatcherQueue.TryEnqueue(DispatcherQueuePriority.Normal, ()
=> {
                _remoteCameraCollection.Add(group);
            });
        }
    }
    private async Task RemoveDevice(string id)
    {
        _dispatcherQueue.TryEnqueue(DispatcherQueuePriority.Normal, () =>
        {
            var existing = _remoteCameraCollection.FirstOrDefault(item =>
item.Id == id);
            if (existing != null)
            {
                _remoteCameraCollection.Remove(existing);
            }
        });
    }
```

C++/WinRT

```
struct RemoteCameraPairingHelper
{
```

```
    RemoteCameraPairingHelper(DispatcherQueue uiDispatcher) :
        m_dispatcherQueue(uiDispatcher)
    {
        m_remoteCameraCollection =
winrt::single_threaded_observable_vector<MediaFrameSourceGroup>();
        auto remoteCameraAqs =
            LR"(System.Devices.InterfaceClassGuid:="{B8238652-B500-41EB-
B4F3-4234F7F5AE99}")"
            LR"(AND
System.Devices.InterfaceEnabled:=System.StructuredQueryType.Boolean#True)";

        m_watcher = DeviceInformation::CreateWatcher(remoteCameraAqs,
nullptr);

        m_watcherAddedAutoRevoker = m_watcher.Added(winrt::auto_revoke, {
this, &RemoteCameraPairingHelper::Watcher_Added });
        m_watcherRemovedAutoRevoker = m_watcher.Removed(winrt::auto_revoke,
{ this, &RemoteCameraPairingHelper::Watcher_Removed });
        m_watcherUpdatedAutoRevoker = m_watcher.Updated(winrt::auto_revoke,
{ this, &RemoteCameraPairingHelper::Watcher_Updated });
        m_watcher.Start();
    }
    ~RemoteCameraPairingHelper()
    {
        m_watcher.Stop();
    }
    IObservableVector<MediaFrameSourceGroup> FrameSourceGroups()
    {
        return m_remoteCameraCollection;
    }
    winrt::fire_and_forget Watcher_Added(DeviceWatcher /* sender */,
DeviceInformation args)
    {
        co_await AddDeviceAsync(args.Id());
    }
    winrt::fire_and_forget Watcher_Removed(DeviceWatcher /* sender */,

Communication

Article • 12/22/2023

This article provides an index of development features that are related to scenarios involving communication in Windows apps.

> **Note**
>
> The **Windows App SDK** currently does not provide APIs related to communication scenarios.

Windows OS features

Windows 10 and later OS releases provide a wide variety of APIs related to communication scenarios for apps. These features are available via a combination of WinRT and Win32 (C++ and COM) APIs provided by the Windows SDK.

WinRT APIs

The following articles provide information about features available via WinRT APIs provided by the Windows SDK.

Expand table

Article	Description
App-to-app communication	Learn how to share data between apps, including how to use the Share contract, copy and paste, drag and drop, and app services.
Interprocess communication	Learn about ways to perform interprocess communication (IPC) between UWP apps, packaged desktop apps, and unpackaged desktop apps.
Networking and web services	Learn about networking and web services technologies that are available to apps.
Sharing named objects	Learn how to share named objects between UWP apps, packaged desktop apps, and unpackaged desktop apps.

Win32 (C++ and COM) APIs

The following articles provide information about features available via Win32 (C++ and COM) APIs provided by the Windows SDK.

Manage resources with MRT Core

Article • 03/13/2023

MRT Core is a streamlined version of the modern Windows Resource Management System that is distributed as part of the Windows App SDK.

MRT Core has both build-time and run-time features. At build time, the system creates an index of all the different variants of the resources that are packaged up with your app. This index is the Package Resource Index, or PRI, and it's also included in your app's package.

Prerequisites

To use MRT Core APIs in the Windows App SDK:

1. Download and install the latest release of the Windows App SDK. For more information, see Get started with WinUI.
2. Follow the instructions to Create your first WinUI 3 project or to use the Windows App SDK in an existing project.

To learn more about the availability of MRT Core in the Windows App SDK, see release channels.

Package Resource Index (PRI) file

Every app package should contain a binary index of the resources in the app. This index is created at build time and it is contained in one or more PRI files. Each PRI file contains a named collection of resources, referred to as a resource map.

A PRI file contains actual string resources. Embedded binary and file path resources are indexed directly from the project files. A package typically contains a single PRI file per language, named **resources.pri**. The **resources.pri** file at the root of each package is automatically loaded when the ResourceManager object is instantiated.

PRI files contain only data, so they don't use the portable executable (PE) format. They are specifically designed to be data-only.

> **Note**
>
> For .NET apps, in Windows App SDK version 0.8 and onward, the **Build Action** file property for resource files in Visual Studio is automatically set, reducing the need

for manual project configuration. Version 1.0 introduced issue 1674. This is fixed in 1.1 (from the stable channel), but the fix requires .NET SDK 6.0.300 or later. If you're using a lower version of the .NET SDK, please continue to use the workaround in the 1.0 release notes.

Access app resources with MRT Core

MRT Core provides several different ways to access your app resources.

> **Note**
>
> In Windows App SDK 1.0 Preview 1 and later releases, MRT Core APIs are in the Microsoft.Windows.ApplicationModel.Resources namespace. In earlier releases, they are in the Microsoft.ApplicationModel.Resources namespace.

Basic functionality with ResourceLoader

The simplest way to access your app resources programmatically is by using the ResourceLoader class. **ResourceLoader** provides you basic access to string resources from the set of resource files, referenced libraries, or other packages.

Advanced functionality with ResourceManager

The ResourceManager class provides additional info about resources, such as enumeration and inspection. This goes beyond what the **ResourceLoader** class provides.

A ResourceCandidate object represents a single concrete resource value and its qualifiers, such as the string "Hello World" for English, or "logo.scale-100.jpg" as a qualified image resource that's specific to the scale-100 resolution.

Resources available to an app are stored in hierarchical collections, which you can access with a ResourceMap object. The **ResourceManager** class provides access to the various top-level **ResourceMap** instances used by the app, which correspond to the various packages for the app. The ResourceManager.MainResourceMap value corresponds to the resource map for the current app package, and it excludes any referenced framework packages. Each **ResourceMap** is named for the package name that is specified in the package's manifest. Within a **ResourceMap** are subtrees (see ResourceMap.GetSubtree). The subtrees typically correspond to the resource files that contains the resource.

The **ResourceManager** not only supports access to an app's string resources, it also maintains the ability to enumerate and inspect the various file resources as well. In order to avoid collisions between files and other resources that originate from within a file, indexed file paths all reside within a reserved "Files" **ResourceMap** subtree. For example, the file '\Images\logo.png' corresponds to the resource name 'Files/images/logo.png'.

Qualify resource selection with ResourceContext

Resource candidates are chosen based on a particular ResourceContext, which is a collection of resource qualifier values (language, scale, contrast, and so on). A default context uses the app's current configuration for each qualifier value, unless overridden. For example, resources such as images can be qualified for scale, which varies from one monitor to another and hence from one application view to another. For this reason, each application view has a distinct default context. Whenever you retrieve a resource candidate, you should pass in a **ResourceContext** instance to obtain the most appropriate value for a given view.

Sample

For a sample that demonstrates how to use the MRT Core API, see the MRT Core sample.

Tailor your resources for language, scale, high contrast, and other qualifiers

Article • 08/19/2024

This topic explains the general concept of resource qualifiers, how to use them, and the purpose of each of the qualifier names. See **ResourceContext.QualifierValues** for a reference table of all the possible qualifier values.

Your app can load assets and resources that are tailored to runtime contexts such as display language, high contrast, display scale factor, and many others. The way you do this is to name your resources' folders or files to match the qualifier names and qualifier values that correspond to those contexts. For example, you may want your app to load a different set of image assets in high contrast mode.

For more info about the value proposition of localizing your app, see Globalization and localization.

Qualifier name, qualifier value, and qualifier

A qualifier name is a key that maps to a set of qualifier values. Here are the qualifier name and qualifier values for contrast.

Expand table

Context	Qualifier name	Qualifier values
The high contrast setting	contrast	standard, high, black, white

You combine a qualifier name with a qualifier value to form a qualifier. `<qualifier name>-<qualifier value>` is the format of a qualifier. `contrast-standard` is an example of a qualifier.

So, for high contrast, the set of qualifiers is `contrast-standard`, `contrast-high`, `contrast-black`, and `contrast-white`. Qualifier names and qualifier values are not case sensitive. For example, `contrast-standard` and `Contrast-Standard` are the same qualifier.

Use qualifiers in folder names

Here is an example of using qualifiers to name folders that contain asset files. Use qualifiers in folder names if you have several asset files per qualifier. That way, you set

the qualifier once at the folder level, and the qualifier applies to everything inside the folder.

Console

```
\Assets\Images\contrast-standard\<logo.png, and other image files>
\Assets\Images\contrast-high\<logo.png, and other image files>
\Assets\Images\contrast-black\<logo.png, and other image files>
\Assets\Images\contrast-white\<logo.png, and other image files>
```

If you name your folders as in the example above, then your app uses the high contrast setting to load resource files from the folder named for the appropriate qualifier. So, if the setting is High Contrast Black, then the resource files in the `\Assets\Images\contrast-black` folder are loaded. If the setting is None (that is, the computer is not in high contrast mode), then the resource files in the `\Assets\Images\contrast-standard` folder are loaded.

Use qualifiers in file names

Instead of creating and naming folders, you can use a qualifier to name the resource files themselves. You might prefer to do this if you only have one resource file per qualifier. Here's an example.

Console

```
\Assets\Images\logo.contrast-standard.png
\Assets\Images\logo.contrast-high.png
\Assets\Images\logo.contrast-black.png
\Assets\Images\logo.contrast-white.png
```

The file whose name contains the qualifier most appropriate for the setting is the one that is loaded. This matching logic works the same way for file names as for folder names.

Reference a string or image resource by name

See the following topics for more info about how to reference a string or image resource by name:

- Refer to a string resource identifier from XAML markup
- Refer to a string resource identifier from code
- Reference an image or other asset from XAML markup and code

Actual and neutral qualifier matches

You don't need to provide a resource file for *every* qualifier value. For example, if you find that you only need one visual asset for high contrast and one for standard contrast, then you can name those assets like this.

Console

```
\Assets\Images\logo.contrast-high.png
\Assets\Images\logo.png
```

The first file name contains the `contrast-high` qualifier. That qualifier is an *actual* match for any high contrast setting when high contrast is *on*. In other words, it's a close match so it's preferred. An *actual* match can only occur if the qualifier contains an *actual* value, as this one does. In this case, `high` is an *actual* value for `contrast`.

The file named `logo.png` has no contrast qualifier on it at all. The absence of a qualifier is a *neutral* value. If no preferred match can be found, then the neutral value serves as a fallback match. In this example, if high contrast is *off*, then there is no actual match. The *neutral* match is the best match that can be found, and so the asset `logo.png` is loaded.

If you were to change the name of `logo.png` to `logo.contrast-standard.png`, then the file name would contain an actual qualifier value. With high contrast off, there would be an actual match with `logo.contrast-standard.png`, and that's the asset file that would be loaded. So, the same files would be loaded, under the same conditions, but because of different matches.

If you only need one set of assets for high contrast and one set for standard contrast, then you can use folder names instead of file names. In this case, omitting the folder name entirely gives you the neutral match.

Console

```
\Assets\Images\contrast-high\<logo.png, and other images to load when high
contrast theme is not None>
\Assets\Images\<logo.png, and other images to load when high contrast theme
is None>
```

For more details on how qualifier matching works, see Manage resources with MRT Core.

Multiple qualifiers

You can combine qualifiers in folder and file names. For example, you may want your app to load image assets when high contrast mode is on *and* the display scale factor is 400. One way to do this is with nested folders.

```
Console

\Assets\Images\contrast-high\scale-400\<logo.png, and other image files>
```

For `logo.png` and the other files to be loaded, the settings must match *both* qualifiers.

Another option is to combine multiple qualifiers in one folder name.

```
Console

\Assets\Images\contrast-high_scale-400\<logo.png, and other image files>
```

In a folder name, you combine multiple qualifiers separated with an underscore. `<qualifier1>[_<qualifier2>...]` is the format.

You can combine multiple qualifiers in a file name in the same format.

```
Console

\Assets\Images\logo.contrast-high_scale-400.png
```

Depending on the tools and workflow you use for asset-creation, or on what you find easiest to read and/or manage, you can either choose a single naming strategy for all qualifiers, or you can combine them for different qualifiers.

AlternateForm

The `alternateform` qualifier is used to provide an alternate form of a resource for some special purpose. This is typically used only by Japanese app developers to provide a furigana string for which the value `msft-phonetic` is reserved (see the section "Support Furigana for Japanese strings that can be sorted" in How to prepare for localization).

Either your target system or your app must provide a value against which `alternateform` qualifiers are matched. Do not use the `msft-` prefix for your own custom `alternateform` qualifier values.

Configuration

It's unlikely that you'll need the `configuration` qualifier name. It can be used to specify resources that are applicable only to a given authoring-time environment, such as test-only resources.

The `configuration` qualifier is used to load a resource that best matches the value of the `MS_CONFIGURATION_ATTRIBUTE_VALUE` environment variable. So, you can set the variable to the string value that has been assigned to the relevant resources, for example `designer`, or `test`.

Contrast

The `contrast` qualifier is used to provide resources that best match high contrast settings.

DXFeatureLevel

It's unlikely that you'll need the `dxfeaturelevel` qualifier name. It was designed to be used with Direct3D game assets, to cause downlevel resources to be loaded to match a particular downlevel hardware configuration of the time. But the prevalence of that hardware configuration is now so low that we recommend you don't use this qualifier.

HomeRegion

The `homeregion` qualifier corresponds to the user's setting for country or region. It represents the home location of the user. Values include any valid BCP-47 region tag. That is, any **ISO 3166-1 alpha-2** two-letter region code, plus the set of **ISO 3166-1 numeric** three-digit geographic codes for composed regions (see United Nations Statistic Division M49 composition of region codes). Codes for "Selected economic and other groupings" are not valid.

Language

A `language` qualifier corresponds to the display language setting. Values include any valid BCP-47 language tag. For a list of languages, see the IANA language subtag registry.

If you want your app to support different display languages, and you have string literals in your code or in your XAML markup, then move those strings out of the code/markup

and into a Resources File (`.resw`). You can then make a translated copy of that Resources File for each language that your app supports.

You typically use a `language` qualifier to name the folders that contain your Resources Files (`.resw`).

```
Console

\Strings\language-en\Resources.resw
\Strings\language-ja\Resources.resw
```

You can omit the `language-` part of a `language` qualifier (that is, the qualifier name). You can't do this with the other kinds of qualifiers; and you can only do it in a folder name.

```
Console

\Strings\en\Resources.resw
\Strings\ja\Resources.resw
```

Instead of naming folders, you can use `language` qualifiers to name the Resources Files themselves.

```
Console

\Strings\Resources.language-en.resw
\Strings\Resources.language-ja.resw
```

See Localize your UI strings for more information on making your app localizable by using string resources, and how to reference a string resource in your app.

LayoutDirection

A `layoutdirection` qualifier corresponds to the layout direction of the display language setting. For example, an image may need to be mirrored for a right-to-left language such as Arabic or Hebrew. Layout panels and images in your UI will respond to layout direction appropriately if you set their FlowDirection property (see Adjust layout and fonts, and support RTL). However, the `layoutdirection` qualifier is for cases where simple flipping isn't adequate, and it allows you to respond to the directionality of specific reading order and text alignment in more general ways.

Scale

Windows automatically selects a scale factor for each display based on its DPI (dots-per-inch) and the viewing distance of the device. See Effective pixels and scale factor. You should create your images at several recommended sizes (at least 100, 200, and 400) so that Windows can either choose the perfect size or can use the nearest size and scale it. So that Windows can identify which physical file contains the correct size of image for the display scale factor, you use a `scale` qualifier. The scale of a resource matches the value of DisplayInformation.ResolutionScale, or the next-largest-scaled resource.

Here's an example of setting the qualifier at the folder level.

Console

```
\Assets\Images\scale-100\<logo.png, and other image files>
\Assets\Images\scale-200\<logo.png, and other image files>
\Assets\Images\scale-400\<logo.png, and other image files>
```

And this example sets it at the file level.

Console

```
\Assets\Images\logo.scale-100.png
\Assets\Images\logo.scale-200.png
\Assets\Images\logo.scale-400.png
```

For info about qualifying a resource for both `scale` and `targetsize`, see Qualify an image resource for targetsize.

TargetSize

The `targetsize` qualifier is primarily used to specify file type association icons or protocol icons to be shown in File Explorer. The qualifier value represents the side length of a square image in raw (physical) pixels. The resource whose value matches the View setting in File Explorer is loaded; or the resource with the next-largest value in the absence of an exact match.

You can define assets that represent several sizes of `targetsize` qualifier value for the App Icon (`/Assets/Square44x44Logo.png`) in the Visual Assets tab of the app package manifest designer.

For info about qualifying a resource for both `scale` and `targetsize`, see Qualify an image resource for targetsize.

Theme

The `theme` qualifier is used to provide resources that best match the default app mode setting, or your app's override using Application.RequestedTheme.

Shell light theme and unplated resources

The *Windows 10 May 2019 Update* introduced a new "light" theme for the Windows Shell. As a result, some application assets that were previously shown on a dark background will now be shown on a light background. For apps that apps that provided altform-unplated assets for the taskbar and window switchers (Alt+Tab, Task View, etc), you should verify that they have acceptable contrast on a light background.

Providing light theme specific assets

Apps that want to provide a tailored resource for shell light theme can use a new alternate form resource qualifier: `altform-lightunplated`. This qualifier mirrors the existing altform-unplated qualifier.

Downlevel considerations

Apps should not use the `theme-light` qualifier with the `altform-unplated` qualifier. This will cause unpredictable behavior on RS5 and earlier versions of Windows due to the way resources are loaded for the Taskbar. On earlier versions of windows, the theme-light version may be used incorrectly. The `altform-lightunplated` qualifier avoids this issue.

Compatibility behavior

For backwards compatibility, Windows includes logic to detect a monochromatic icons and check whether it contrasts with the intended background. If the icon fails to meet contrast requirements, Windows will look for a contrast-white version of the asset. If that's not available, Windows will fall back to using the plated version of the asset.

Localize strings in your UI and the app package manifest

Article • 08/19/2024

For more info about the value proposition of localizing your Windows App SDK app, see Globalization and localization.

If you want your app to support different display languages, and you have string literals in your code or XAML markup or app package manifest, then move those strings into a Resources File (.resw). You can then make a translated copy of that Resources File for each language that your app supports.

Hardcoded string literals can appear in imperative code or in XAML markup, for example as the **Text** property of a **TextBlock**. They can also appear in your app package manifest source file (the `Package.appxmanifest` file), for example as the value for Display name on the Application tab of the Visual Studio Manifest Designer. Move these strings into a Resources File (.resw), and replace the hardcoded string literals in your app and in your manifest with references to resource identifiers.

Unlike image resources, where only one image resource is contained in an image resource file, *multiple* string resources are contained in a string resource file. A string resource file is a Resources File (.resw), and you typically create this kind of resource file in a \Strings folder in your project. For background on how to use qualifiers in the names of your Resources Files (.resw), see Tailor your resources for language, scale, and other qualifiers.

Store strings in a resources file

1. Set your app's default language.
   a. With your solution open in Visual Studio, open `Package.appxmanifest`.
   b. On the Application tab, confirm that the Default language is set appropriately (for example, "en" or "en-US"). The remaining steps will assume that you have set the default language to "en-US".

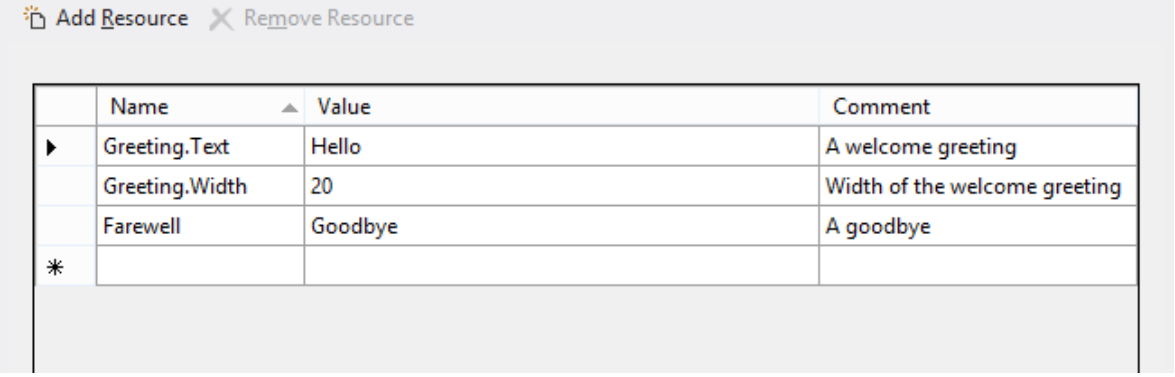
> **Note**
>
> At a minimum, you need to provide string resources localized for this default language. Those are the resources that will be loaded if no better match can be found for the user's preferred language or display language settings.

2. Create a Resources File (.resw) for the default language.
   a. Under your project node, create a new folder and name it `Strings`.
   b. Under `Strings`, create a new sub-folder and name it `en-US`.
   c. Under `en-US`, create a new Resources File (.resw) (under the **WinUI** file types in the **Add New Item** dialog) and confirm that it is named `Resources.resw`.

> **Note**
>
> If you have .NET Resources Files (.resx) that you want to port, see Porting XAML and UI.

3. Open `Resources.resw` and add these string resources.

`Strings/en-US/Resources.resw`



In this example, "Greeting" is a string resource identifier that you can refer to from your markup, as we'll show. For the identifier "Greeting", a string is provided for a Text property, and a string is provided for a Width property. "Greeting.Text" is an example of a property identifier because it corresponds to a property of a UI element. You could also, for example, add "Greeting.Foreground" in the Name column, and set its Value to "Red". The "Farewell" identifier is a simple string resource identifier; it has no sub-properties and it can be loaded from imperative code, as we'll show. The Comment column is a good place to provide any special instructions to translators.

In this example, since we have a simple string resource identifier entry named "Farewell", we cannot *also* have property identifiers based on that same identifier. So, adding "Farewell.Text" would cause a Duplicate Entry error when building `Resources.resw`.

Resource identifiers are case insensitive, and must be unique per resource file. Be sure to use meaningful resource identifiers to provide additional context for translators. And don't change the resource identifiers after the string resources are

sent for translation. Localization teams use the resource identifier to track additions, deletions, and updates in the resources. Changes in resource identifiers —which is also known as "resource identifiers shift"—require strings to be retranslated, because it will appear as though strings were deleted and others added.

Refer to a string resource identifier from XAML

You use an x:Uid directive to associate a control or other element in your markup with a string resource identifier.

XAML

```
<TextBlock x:Uid="Greeting"/>
```

At run-time, `\Strings\en-US\Resources.resw` is loaded (since right now that's the only Resources File in the project). The **x:Uid** directive on the **TextBlock** causes a lookup to take place, to find property identifiers inside `Resources.resw` that contain the string resource identifier "Greeting". The "Greeting.Text" and "Greeting.Width" property identifiers are found and their values are applied to the **TextBlock**, overriding any values set locally in the markup. The "Greeting.Foreground" value would be applied, too, if you'd added that. But only property identifiers are used to set properties on XAML markup elements, so setting **x:Uid** to "Farewell" on this TextBlock would have no effect. `Resources.resw` *does* contain the string resource identifier "Farewell", but it contains no property identifiers for it.

When assigning a string resource identifier to a XAML element, be certain that *all* the property identifiers for that identifier are appropriate for the XAML element. For example, if you set `x:Uid="Greeting"` on a **TextBlock** then "Greeting.Text" will resolve because the **TextBlock** type has a Text property. But if you set `x:Uid="Greeting"` on a **Button** then "Greeting.Text" will cause a run-time error because the **Button** type does not have a Text property. One solution for that case is to author a property identifier named "ButtonGreeting.Content", and set `x:Uid="ButtonGreeting"` on the **Button**.

Instead of setting **Width** from a Resources File, you'll probably want to allow controls to dynamically size to content.

> ⓘ **Note**
>
> For attached properties, you need a special syntax in the **Name** column of a .resw file. For example, to set a value for the AutomationProperties.Name attached

property for the "Greeting" identifier, this is what you would enter in the **Name** column.

XML

```
Greeting.[using:Microsoft.UI.Xaml.Automation]AutomationProperties.Name
```

Refer to a string resource identifier from code

You can explicitly load a string resource based on a simple string resource identifier.

C#

```
var resourceLoader = new
Microsoft.Windows.ApplicationModel.Resources.ResourceLoader();
this.myXAMLTextBlockElement.Text = resourceLoader.GetString("Farewell");
```

You can use this same code from within a Class Library project. At runtime, the resources of the app that's hosting the library are loaded. We recommend that a library loads resources from the app that hosts it, since the app is likely to have a greater degree of localization. If a library does need to provide resources then it should give its hosting app the option to replace those resources as an input.

If a resource name is segmented (it contains "." characters), then replace dots with forward slash ("/") characters in the resource name. Property identifiers, for example, contain dots; so you'd need to do this substitution in order to load one of those from code.

C#

```
this.myXAMLTextBlockElement.Text = resourceLoader.GetString("Fare/Well"); //
<data name="Fare.Well" ...> ...
```

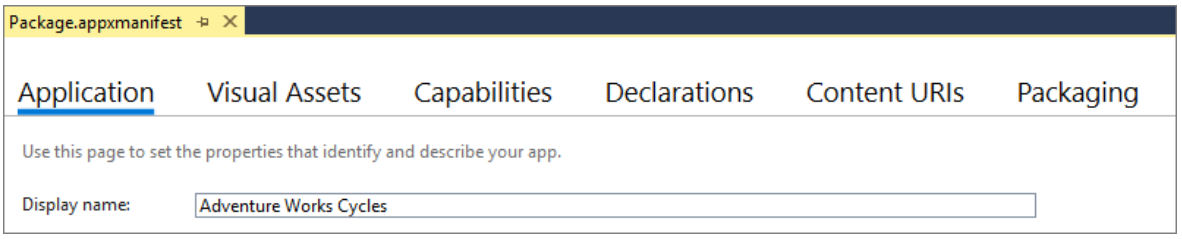
If in doubt, you can use MakePri.exe to dump your app's PRI file. Each resource's `uri` is shown in the dumped file.

XML

```
<ResourceMapSubtree name="Fare"><NamedResource name="Well" uri="ms-
resource://<GUID>/Resources/Fare/Well">...
```

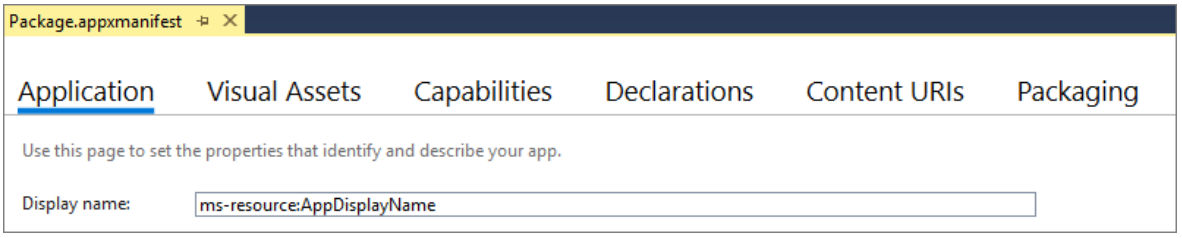
Refer to a string resource identifier from your app package manifest

1. Open your app package manifest source file (the `Package.appxmanifest` file), in which by default your app's `Display name` is expressed as a string literal.



2. To make a localizable version of this string, open `Resources.resw` and add a new string resource with the name "AppDisplayName" and the value "Adventure Works Cycles".

3. Replace the Display name string literal with a reference to the string resource identifier that you just created ("AppDisplayName"). You use the `ms-resource` URI (Uniform Resource Identifier) scheme to do this.



4. Repeat this process for each string in your manifest that you want to localize. For example, your app's Short name (which you can configure to appear on your app's tile on Start). For a list of all items in the app package manifest that you can localize, see Localizable manifest items.

Localize the string resources

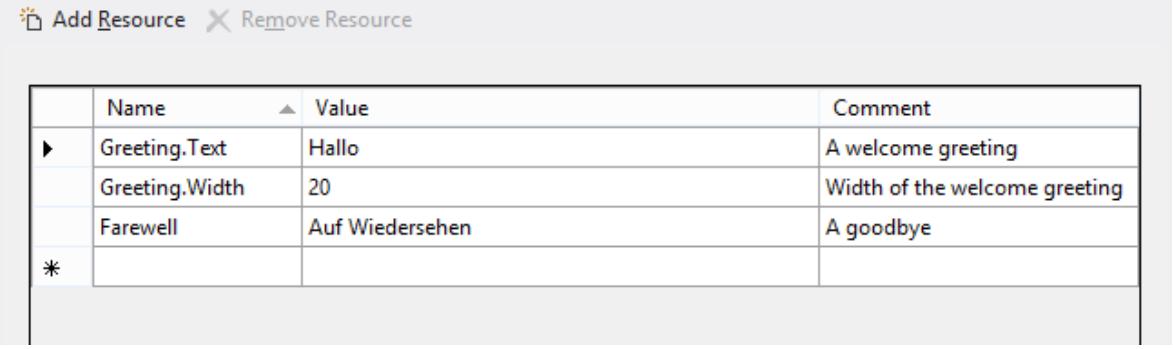
1. Make a copy of your Resources File (.resw) for another language.
   a. Under "Strings", create a new sub-folder and name it "de-DE" for Deutsch (Deutschland).

> **Note**
>
> For the folder name, you can use any BCP-47 language tag. See Tailor your resources for language, scale, and other qualifiers for details on the

language qualifier and a list of common language tags. 2. Make a copy of `Strings/en-US/Resources.resw` in the `Strings/de-DE` folder.

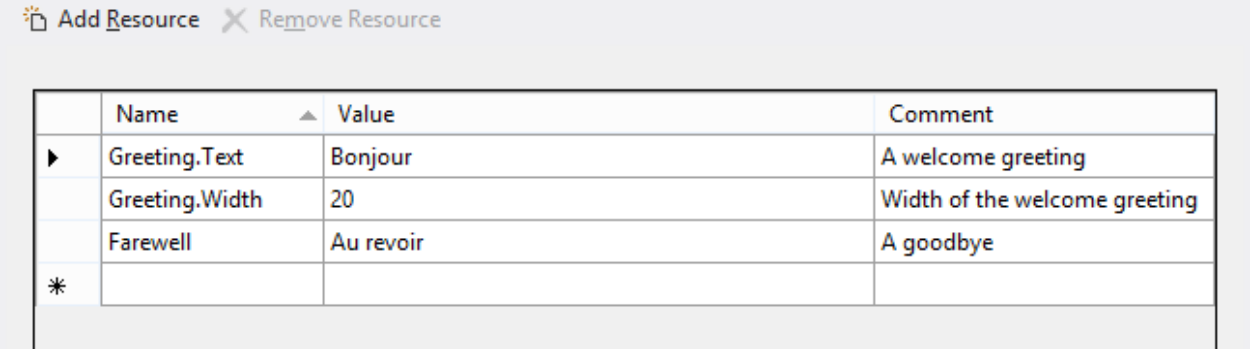
2. Translate the strings.
   a. Open `Strings/de-DE/Resources.resw` and translate the values in the Value column. You don't need to translate the comments.

`Strings/de-DE/Resources.resw`



If you like, you can repeat steps 1 and 2 for a further language.

`Strings/fr-FR/Resources.resw`



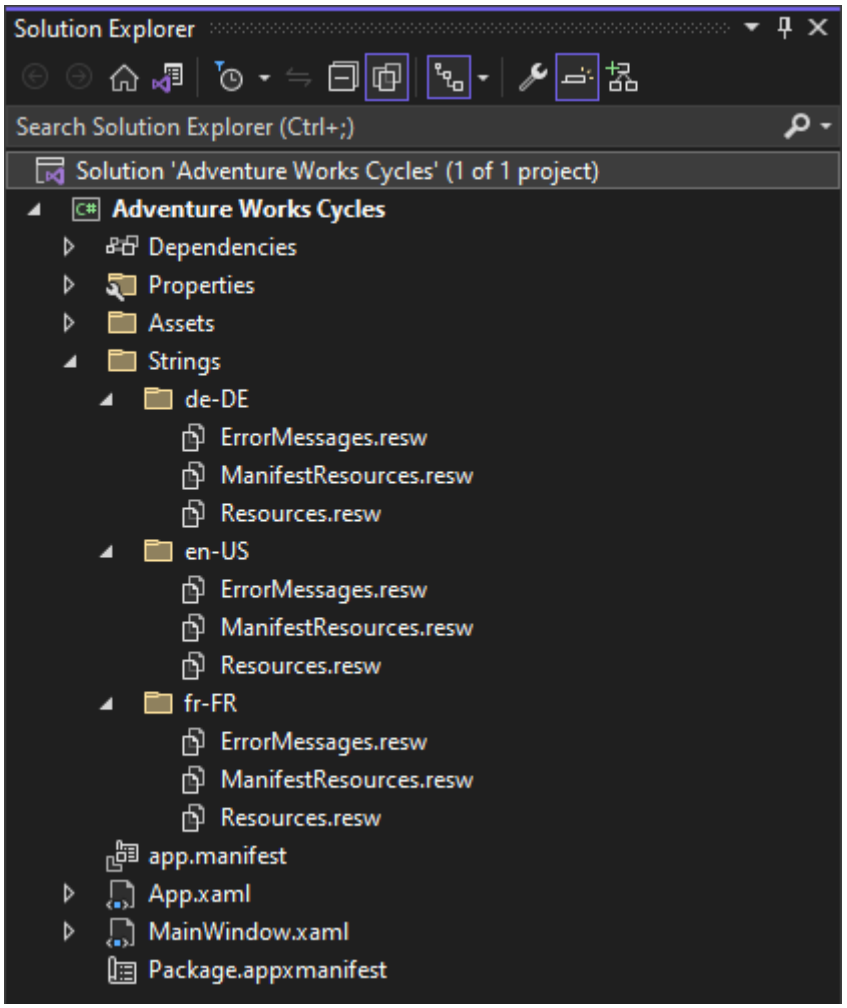
Test your app

Test the app for your default display language. You can then change the display language in **Settings** > **Time & Language** > **Region & language** > **Languages** and re-test your app. Look at strings in your UI and also in the shell (for example, your title bar—which is your Display name—and the Short name on your tiles).

> **Note**
>
> If a folder name can be found that matches the display language setting, then the Resources File inside that folder is loaded. Otherwise, fallback takes place, ending with the resources for your app's default language.

Factoring strings into multiple Resources Files

You can keep all of your strings in a single Resources File (resw), or you can factor them across multiple Resources Files. For example, you might want to keep your error messages in one Resources File, your app package manifest strings in another, and your UI strings in a third. This is what your folder structure would look like in that case.



To scope a string resource identifier reference to a particular file, you just add `/<resources-file-name>/` before the identifier. The markup example below assumes that `ErrorMessages.resw` contains a resource whose name is "PasswordTooWeak.Text" and whose value describes the error.

XAML

```
<TextBlock x:Uid="/ErrorMessages/PasswordTooWeak"/>
```

You only need to add `/<resources-file-name>/` before the string resource identifier for Resources Files *other than* `Resources.resw`. That's because "Resources.resw" is the default file name, so that's what's assumed if you omit a file name (as we did in the earlier examples in this topic).

The code example below assumes that `ErrorMessages.resw` contains a resource whose name is "MismatchedPasswords" and whose value describes the error.

C#

```
var resourceLoader = new
Microsoft.Windows.ApplicationModel.Resources.ResourceLoader("ErrorMessages")
;
this.myXAMLTextBlockElement.Text =
resourceLoader.GetString("MismatchedPasswords");
```

If you were to move your "AppDisplayName" resource out of `Resources.resw` and into `ManifestResources.resw`, then in your app package manifest you would change `ms-resource:AppDisplayName` to `ms-resource:/ManifestResources/AppDisplayName`.

If a resource file name is segmented (it contains "." characters), then leave the dots in the name when you reference it. **Don't** replace dots with forward slash ("/") characters, like you would for a resource name.

C#

```
var resourceLoader = new
Microsoft.Windows.ApplicationModel.Resources.ResourceLoader("Err.Msgs");
```

If in doubt, you can use MakePri.exe to dump your app's PRI file. Each resource's `uri` is shown in the dumped file.

XML

```
<ResourceMapSubtree name="Err.Msgs"><NamedResource
name="MismatchedPasswords" uri="ms-
resource://<GUID>/Err.Msgs/MismatchedPasswords">...
```

Load a string for a specific language or other context

The default ResourceContext (obtained when creating a ResourceLoader) contains a qualifier value for each qualifier name, representing the default runtime context (in other words, the settings for the current user and machine). Resources Files (.resw) are matched—based on the qualifiers in their names—against the qualifier values in that runtime context.

But there might be times when you want your app to override the system settings and be explicit about the language, scale, or other qualifier value to use when looking for a matching Resources File to load. For example, you might want your users to be able to select an alternative language for tooltips or error messages.

You can do that by constructing a new **ResourceContext**, overriding its values, and then using that context object in your string lookups.

```
C#

var resourceManager = new
Microsoft.Windows.ApplicationModel.Resources.ResourceManager();
var resourceContext = resourceManager.CreateResourceContext();
resourceContext.QualifierValues["Language"] = "de-DE";
var resourceMap = resourceManager.MainResourceMap.GetSubtree("Resources");
this.myXAMLTextBlockElement.Text = resourceMap.GetValue("Farewell",
resourceContext).ValueAsString;
```

Using **QualifierValues** as in the code example above works for any qualifier. For the special case of Language, you can alternatively do this instead.

```
C#

resourceContext.Languages = new string[] { "de-DE" };
```

Load strings from a Class Library

The string resources of a referenced Class Library are typically added into a subfolder of the package in which they're included during the build process. The resource identifier of such a string usually takes the form *LibraryName/ResourcesFileName/ResourceIdentifier*.

A library can get a **ResourceLoader** for its own resources. For example, the following code illustrates how either a library or an app that references it can get a **ResourceLoader** for the library's string resources.

```
C#

var resourceLoader = new
Microsoft.Windows.ApplicationModel.Resources.ResourceLoader("ContosoControl/
Resources");
this.myXAMLTextBlockElement.Text =
resourceLoader.GetString("exampleResourceName");
```

If in doubt about the path, you can specify MakePri.exe command line options to dump your component or library's PRI file. Each resource's `uri` is shown in the dumped file.

```xml
<NamedResource name="exampleResourceName" uri="ms-
resource://Contoso.Control/Contoso.Control/ReswFileName/exampleResourceName"
>...
```

Loading strings from other packages

The resources for an app package are managed and accessed through the package's own top-level ResourceMap that's accessible from the ResourceManager. Within each package, various components can have their own **ResourceMap** subtrees, which you can access via ResourceMap.GetSubtree.

A framework package can access its own resources with an absolute resource identifier URI. Also see URI schemes in the UWP documentation for more information.

Loading strings in unpackaged applications

As of Windows Version 1903 (May 2019 Update), unpackaged applications can also leverage the Resource Management System.

Just create your Windows App SDK user controls/libraries and store any strings in a resources file. You can then refer to a string resource identifier from XAML, refer to a string resource identifier from code, or load strings from a Class Library.

To use resources in unpackaged applications, you should do a few things:

1. Use the overloaded constructor of **ResourceManager** to pass file name of your app's .pri file when resolving resources from code as there is no default view in unpackaged scenarios.
2. Use MakePri.exe to manually generate your app's resources.pri file.

    - Run `makepri new /pr <PROJECTROOT> /cf <PRICONFIG> /of resources.pri`
    - The <PRICONFIG> must omit the "<packaging>" section so that all resources are bundled in a single resources.pri file. If using the default MakePri.exe configuration file created by createconfig, you need to delete the "<packaging>" section manually after it is created.
    - The <PRICONFIG> must contain all relevant indexers required to merge all resources in your project into a single resources.pri file. The default

MakePri.exe configuration file created by createconfig includes all indexers.

- If you don't use the default config, make sure the PRI indexer is enabled (review the default config for how to do this) to merge PRIs found from project references, NuGet references, and so on, that are located within the project root.

> **Note**
>
> By omitting `/IndexName`, and by the project not having an app manifest, the IndexName/root namespace of the PRI file is automatically set to *Application*, which the runtime understands for unpackaged apps (this removes the previous hard dependency on package ID). When specifying resource URIs, ms-resource:/// references that omit the root namespace infer *Application* as the root namespace for unpackaged apps (or you can specify *Application* explicitly as in ms-resource://Application/).

3. Copy the PRI file to the build output directory of the .exe
4. Run the .exe

> **Note**
>
> The Resource Management System uses the system display language rather than the user preferred language list when resolving resources based on language in unpackaged apps. The user preferred language list is only used for Windows App SDK packaged apps.

> **Important**
>
> You must manually rebuild PRI files whenever resources are modified. We recommend using a post-build script that handles the MakePri.exe command and copies the resources.pri output to the .exe directory.

- How to load string resources

Load images and assets tailored for scale, theme, high contrast, and others

Article • 10/08/2024

Your app can load image resource files (or other asset files) tailored for display scale factor, theme, high contrast, and other runtime contexts. These images can be referenced from imperative code or from XAML markup, for example as the **Source** property of an Image. They can also appear in your app package manifest source file (the `Package.appxmanifest` file)—for example, as the value for App Icon on the Visual Assets tab of the Visual Studio Manifest Designer—or on your tiles and toasts. By using qualifiers in your images' file names, and optionally dynamically loading them with the help of a ResourceContext, you can cause the most appropriate image file to be loaded that best matches the user's runtime settings for display scale, theme, high contrast, language, and other contexts.

An image resource is contained in an image resource file. You can also think of the image as an asset, and the file that contains it as an asset file; and you can find these kinds of resource files in your project's \Assets folder. For background on how to use qualifiers in the names of your image resource files, see Tailor your resources for language, scale, and other qualifiers.

Some common qualifiers for images are:

- scale
- theme
- contrast
- targetsize

Qualify an image resource for scale, theme, and contrast

The default value for the `scale` qualifier is `scale-100`. So, these two variants are equivalent (they both provide an image at scale 100, or scale factor 1).

Console

```
\Assets\Images\logo.png
\Assets\Images\logo.scale-100.png
```

You can use qualifiers in folder names instead of file names. This is a better strategy when you have several asset files per qualifier. For purposes of illustration, these two variants are equivalent to the two above.

Console

```
\Assets\Images\logo.png
\Assets\Images\scale-100\logo.png
```

The next example shows how you can provide variants of an image resource—named `/Assets/Images/logo.png`—for different settings of display scale, theme, and high contrast. This example uses folder naming.

Console

```
\Assets\Images\contrast-standard\theme-dark
    \scale-100\logo.png
    \scale-200\logo.png
\Assets\Images\contrast-standard\theme-light
    \scale-100\logo.png
    \scale-200\logo.png
\Assets\Images\contrast-high
    \scale-100\logo.png
    \scale-200\logo.png
```

Reference an image or other asset from XAML markup and code

The name—or identifier—of an image resource is its path and file name with any and all qualifiers removed. If you name folders and/or files as in any of the examples in the previous section, then you have a single image resource and its name (as an absolute path) is `/Assets/Images/logo.png`. Here's how you use that name in XAML markup.

XAML

```
<Image x:Name="myXAMLImageElement" Source="ms-
appx:///Assets/Images/logo.png"/>
```

Notice that you use the `ms-appx` URI scheme because you're referring to a file that comes from your app's package. See URI schemes in the UWP documentation. This is how you refer to the same image resource in imperative code.

C#

```
this.myXAMLImageElement.Source = new BitmapImage(new Uri("ms-
appx:///Assets/Images/logo.png"));
```

You can use `ms-appx` to load any arbitrary file from your app package.

C#

```
var uri = new System.Uri("ms-appx:///Assets/anyAsset.ext");
var storagefile = await
Windows.Storage.StorageFile.GetFileFromApplicationUriAsync(uri);
```

The `ms-appx-web` scheme accesses the same files as `ms-appx`, but in the web compartment.

XAML

```
<WebView x:Name="myXAMLWebViewElement" Source="ms-appx-
web:///Pages/default.html"/>
```

C#

```
this.myXAMLWebViewElement.Source = new Uri("ms-appx-
web:///Pages/default.html");
```

For any of the scenarios shown in these examples, use the Uri constructor overload that infers the UriKind. Specify a valid absolute URI including the scheme and authority, or just let the authority default to the app's package as in the example above.

Notice how in these example URIs the scheme ("`ms-appx`" or "`ms-appx-web`") is followed by "`://`" which is followed by an absolute path. In an absolute path, the leading "`/`" causes the path to be interpreted from the root of the package.

> **Note**
>
> The `ms-resource` (for string resources) and `ms-appx(-web)` (for images and other assets) URI schemes perform automatic qualifier matching to find the resource that's most appropriate for the current context. The `ms-appdata` URI scheme (which is used to load app data) does not perform any such automatic matching, but you can respond to the contents of ResourceContext.QualifierValues and explicitly load the appropriate assets from app data using their full physical file name in the URI. For info about app data, see Store and retrieve settings and other app data. Web URI schemes (for example, `http`, `https`, and `ftp`) do not perform automatic

matching, either. For info about what to do in that case, see Hosting and loading images in the cloud.

Absolute paths are a good choice if your image files remain where they are in the project structure. If you want to be able to move an image file, but you're careful that it remains in the same location relative to its referencing XAML markup file, then instead of an absolute path you might want to use a path that's relative to the containing markup file. If you do that, then you needn't use a URI scheme. You will still benefit from automatic qualifier matching in this case, but only because you are using the relative path in XAML markup.

XAML

```
<Image Source="Assets/Images/logo.png"/>
```

Also see Tile and toast support for language, scale, and high contrast.

Reference an image or other asset from a class library

You can load images and other resources from a referenced **Class library (WinUI 3 in Desktop)** project by referencing the resource in a URI that uses the `ms-appx` scheme. The URI should include the name of the class library project and the path to the resource within the class library project. For example, if you have a class library project named `MyClassLibrary` that contains an image named `logo.png` in a folder named `Assets`, you can reference the image in your app project like this:

XAML

```
<Image Source="ms-appx:///MyClassLibrary/Assets/logo.png"/>
```

You'll use this same URI format to reference resources in a class library from XAML markup or from code. For example, you can use the following code to load the image from your class library and put it into a StorageFile object:

C#

```
private async Task<DateTimeOffset> GetLogoCreatedDateAsync()
{
    Uri uri = new($"ms-appx:///MyClassLibrary/Assets/logo.png");
    Windows.Storage.StorageFile file =
        await
```

```
Windows.Storage.StorageFile.GetFileFromApplicationUriAsync(uri);

    return file.DateCreated;
}
```

Note that you can reference images from the class library from both the app project and the class library project itself.

Qualify an image resource for targetsize

You can use the `scale` and `targetsize` qualifiers on different variants of the same image resource; but you can't use them both on a single variant of a resource. Also, you need to define at least one variant without a `targetsize` qualifier. That variant must either define a value for `scale`, or let it default to `scale-100`. So, these two variants of the `/Assets/Square44x44Logo.png` resource are valid.

Console

```
\Assets\Square44x44Logo.scale-200.png
\Assets\Square44x44Logo.targetsize-24.png
```

And these two variants are valid.

Console

```
\Assets\Square44x44Logo.png // defaults to scale-100
\Assets\Square44x44Logo.targetsize-24.png
```

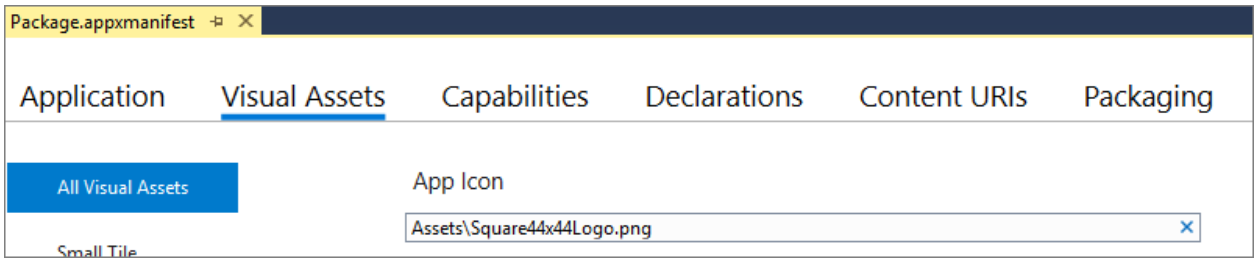
But this variant is not valid.

Console

```
\Assets\Square44x44Logo.scale-200_targetsize-24.png
```

Refer to an image file from your app package manifest

If you name folders and/or files as in either of the two valid examples in the previous section, then you have a single app icon image resource and its name (as a relative path) is `Assets\Square44x44Logo.png`. In your app package manifest, simply refer to the resource by name. There's no need to use any URI scheme.



That's all you need to do, and the OS will perform automatic qualifier matching to find the resource that's most appropriate for the current context. For a list of all items in the app package manifest that you can localize or otherwise qualify in this way, see Localizable manifest items.

Qualify an image resource for layoutdirection

See Mirroring images.

Load an image for a specific language or other context

For more info about the value proposition of localizing your app, see Globalization and localization.

The default ResourceContext contains a qualifier value for each qualifier name, representing the default runtime context (in other words, the settings for the current user and machine). Image files are matched—based on the qualifiers in their names—against the qualifier values in that runtime context.

But there might be times when you want your app to override the system settings and be explicit about the language, scale, or other qualifier value to use when looking for a matching image to load. For example, you might want to control exactly when and which high contrast images are loaded.

You can do that by constructing a new **ResourceContext** (instead of using the default one), overriding its values, and then using that context object in your ResourceMap image lookups with GetValue or TryGetValue.

C#

```
var resourceManager = new
Microsoft.Windows.ApplicationModel.Resources.ResourceManager();
var resourceContext = resourceManager.CreateResourceContext();
resourceContext.QualifierValues["Contrast"] = "high";
var resourceMap = resourceManager.MainResourceMap;
var namedResource = resourceMap.TryGetValue(@"Files/Assets/Logo.png",
```

```
resourceContext);
var imageFileBytes = namedResource.ValueAsBytes;

using (var ms = new InMemoryRandomAccessStream())
{
    using (var writer = new DataWriter(ms.GetOutputStreamAt(0)))
    {
        writer.WriteBytes(imageFileBytes);
        writer.StoreAsync().GetResults();
    }
    var image = new BitmapImage();
    image.SetSource(ms);
    this.myXAMLImageElement.Source = image;
}
```

By default, the ResourceManager class uses the default **ResourceContext**.

Important APIs

The following APIs are imporant to understand when working with image resources:

- ResourceContext
- ResourceMap

Data access in Windows apps?

Article • 08/02/2024

You can store data on the user's device by using a SQLite database. You can also connect your Windows app directly to a SQL Server, Cosmos DB, MySQL, or MongoDB database without having to use an external service layer.

Topics in this section

In this section, you'll learn how to store and retrieve data in a Windows app by using different back-end databases. Each topic provides a guide to help you get started.

Expand table

Topic	Description
Use a SQLite database on Windows	Shows you how to use SQLite to store and retrieve data in a light-weight database on the user's device. SQLite is a server-less, embedded database engine.
Use a SQL Server database in a Windows app	Shows you how to connect directly to a SQL Server database and then store and retrieve data by using classes in the System.Data.SqlClient namespace. No service layer required.
Use a Cosmos DB database in a Windows app	Shows you how to work with a Cosmos DB database and test the connection programmatically. Cosmos DB is a cloud-based document database.
Use a MySQL database in a Windows app	Shows you how to connect to a MySQL database and interact with the database in a Windows application. MySQL is an open source, cross-platform relational database.
Use a MongoDB database in a Windows app	Shows you how to work with a MongoDB database and test the connection programmatically. MongoDB is a cross-platform document database.

Use a SQLite database in a Windows app

Article • 08/01/2024

You can use SQLite to store and retrieve data in a lightweight database on the user's device. This guide shows you how to do it in your Windows App SDK apps.

Some benefits of using SQLite for local storage

✔ SQLite is lightweight and self-contained. It's a code library without any other dependencies. There's nothing to configure.

✔ There's no database server. The client and the server run in the same process.

✔ SQLite is in the public domain so you can freely use and distribute it with your app.

✔ SQLite works across platforms and architectures.

You can read more about SQLite here.

Choose an abstraction layer

We recommend that you use either Entity Framework Core or the open-source SQLite library built by Microsoft.

Entity Framework Core

Entity Framework (EF) is an object-relational mapper that you can use to work with relational data by using domain-specific objects. If you've already used this framework to work with data in other .NET apps, you can use the same code in your Windows App SDK app and it will work with appropriate changes to the connection string.

To try it out, see Getting Started with EF Core.

SQLite library

The Microsoft.Data.Sqlite library implements the interfaces in the System.Data.Common namespace. Microsoft actively maintains these implementations, and they provide an intuitive wrapper around the low-level native SQLite API.

The rest of this guide helps you to use this library.

Set up your solution to use the Microsoft.Data.SQlite library

We'll start with a basic Windows App SDK project, and then install the SQLite NuGet package.

All supported versions of Windows support SQLite, so your app does not have to package SQLite libraries. Instead, your app can use the version of SQLite that comes installed with Windows. This helps you in a few ways.

✔ Reduces the size of your application because you don't have to download the SQLite binary, and then package it as part of your application.

✔ Prevents you from having to push a new version of your app to users in the event that SQLite publishes critical fixes to bugs and security vulnerabilities in SQLite. The Windows version of SQLite is maintained by Microsoft in coordination with SQLite.org.

✔ App load time has the potential to be faster because most likely, the SDK version of SQLite will already be loaded into memory.

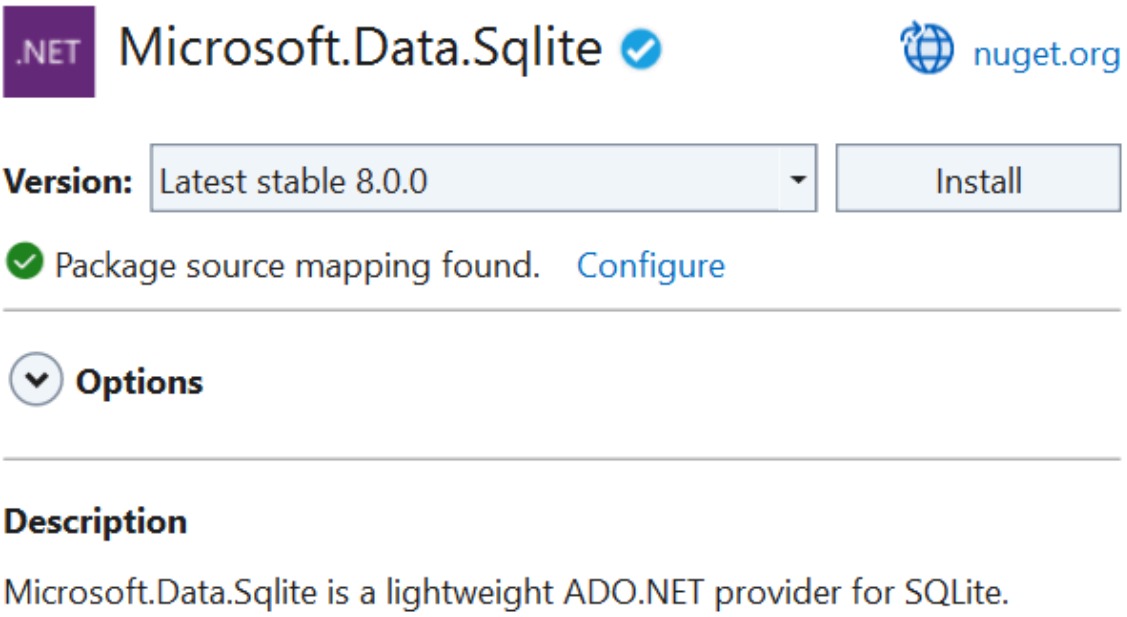
Let's start by adding a class to your project named **DataAccess**. If you plan to share your data access logic with other client code, you can use a .NET class library project to contain your data access code, but we won't use one in our example.

1. Right-click the solution, and then click **Manage NuGet Packages for Solution**.

   At this point, you have a choice. You can use the version of SQLite that is included with Windows or if you have some reason to use a specific version of SQLite, you

can include the SQLite library in your package. We are going to use the version of SQLite that's included with Windows.

2. Choose the **Browse** tab, search for the **Microsoft.Data.SQLite** package, and then install the latest stable version.



Add and retrieve data in a SQLite database

We'll do these things:

[1] Prepare the data access class.

[2] Initialize the SQLite database.

[3] Insert data into the SQLite database.

[4] Retrieve data from the SQLite database.

[5] Add a basic user interface.

Prepare the data access class

Open the `DataAccess` class in your project and make that class static.

> ⓘ **Note**
>
> While our example will place data access code in a static class, this is a design choice and is completely optional.

C#

```
public static class DataAccess
{
}
```

Add the following `using` statements to the top of this file.

C#

```
using Microsoft.Data.Sqlite;
using System.Collections.Generic;
```

Initialize the SQLite database

Add a method to the `DataAccess` class that initializes the SQLite database.

C#

```
public async static void InitializeDatabase()
{
    await ApplicationData.Current.LocalFolder
            .CreateFileAsync("sqliteSample.db",
CreationCollisionOption.OpenIfExists);
    string dbpath = Path.Combine(ApplicationData.Current.LocalFolder.Path,
                                 "sqliteSample.db");
    using (var db = new SqliteConnection($"Filename={dbpath}"))
    {
        db.Open();

        string tableCommand = "CREATE TABLE IF NOT " +
            "EXISTS MyTable (Primary_Key INTEGER PRIMARY KEY, " +
            "Text_Entry NVARCHAR(2048) NULL)";

        var createTable = new SqliteCommand(tableCommand, db);

        createTable.ExecuteReader();
    }
}
```

> **Note**
>
> The code above that uses `ApplicationData` members will only work for packaged apps running in an app container. All other Windows apps should access `ApplicationData` members via the ApplicationDataManager class.

This code creates the SQLite database and stores it in the application's local data store.

In this example, we name the database `sqlliteSample.db` but you can use whatever name you want as long as you use that name in all SqliteConnection objects that you instantiate. In a production application, connection information such as the database filename should be stored in app configuration rather than hard-coded (see **Adding Azure App Configuration by using Visual Studio Connected Services**).

In the constructor of the **App.xaml.cs** file of your project, call the `InitializeDatabase` method of the `DataAccess` class. This will ensure that the database is created or opened each time the app starts.

C#

```
public App()
{
    this.InitializeComponent();

    DataAccess.InitializeDatabase();
}
```

Insert data into the SQLite database

Add a method to the `DataAccess` class that inserts data into the SQLite database. This code uses parameters in the query to prevent SQL injection attacks.

C#

```
public static void AddData(string inputText)
{
    string dbpath = Path.Combine(ApplicationData.Current.LocalFolder.Path,
                                 "sqliteSample.db");
    using (var db = new SqliteConnection($"Filename={dbpath}"))
    {
        db.Open();

        var insertCommand = new SqliteCommand();
        insertCommand.Connection = db;

        // Use parameterized query to prevent SQL injection attacks
        insertCommand.CommandText = "INSERT INTO MyTable VALUES (NULL,
@Entry);";
        insertCommand.Parameters.AddWithValue("@Entry", inputText);

        insertCommand.ExecuteReader();
    }
```

```
}
```

Retrieve data from the SQLite database

Add a method that gets all rows of data from a table in our SQLite database.

C#

```
public static List<string> GetData()
{
    var entries = new List<string>();
    string dbpath = Path.Combine(ApplicationData.Current.LocalFolder.Path,
                                 "sqliteSample.db");
    using (var db = new SqliteConnection($"Filename={dbpath}"))
    {
        db.Open();
        var selectCommand = new SqliteCommand
            ("SELECT Text_Entry from MyTable", db);

        SqliteDataReader query = selectCommand.ExecuteReader();

        while (query.Read())
        {
            entries.Add(query.GetString(0));
        }
    }

    return entries;
}
```

The Read method advances through the rows of returned data. It returns `true` if there are rows left, otherwise it returns `false`.

The GetString method returns the value of the specified column as a string. It accepts an integer value that represents the zero-based column ordinal of the data that you want. You can use similar methods such as GetDataTime and GetBoolean. Choose a method based on what type of data the column contains.

The ordinal parameter isn't as important in this example because we are selecting all of the entries in a single column. However, if multiple columns are part of your query, use the ordinal value to obtain the column you want to pull data from.

Add a basic user interface

In the **MainWindow.xaml** file of the project, add the following XAML.

XAML

```
<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <StackPanel>
        <TextBox x:Name="Input_Box"/>
        <Button Click="AddData">Add</Button>
        <ListView x:Name="Output">
            <ListView.ItemTemplate>
                <DataTemplate>
                    <TextBlock Text="{Binding}"/>
                </DataTemplate>
            </ListView.ItemTemplate>
        </ListView>
    </StackPanel>
</Grid>
```

This basic user interface gives the user a `TextBox` that they can use to type a string that we'll add to the SQLite database. We'll connect the `Button` in this UI to an event handler that will retrieve data from the SQLite database and then show that data in the `ListView`.

In the **MainWindow.xaml.cs** file, add the following handler. This is the method that we associated with the `Click` event of the `Button` in the UI.

C#

```
private void AddData(object sender, RoutedEventArgs e)
{
    DataAccess.AddData(Input_Box.Text);

    Output.ItemsSource = DataAccess.GetData();
}
```

We also want to be sure that any existing data is loaded when the application starts. Add a line of code to the `MainWindow` constructor to call `GetData()`.

C#

```
public MainWindow()
{
    this.InitializeComponent();

    Output.ItemsSource = DataAccess.GetData();
}
```

That's it. Explore the Microsoft.Data.Sqlite to see what other things you can do with your SQLite database. Check out the links below to learn about other ways to use data in

your Windows apps.

Use a SQL Server database in a Windows app

Article • 10/15/2024

Your app can connect directly to a SQL Server database and then store and retrieve data by using classes in the System.Data.SqlClient namespace.

Getting started

In this guide, we'll show you one way to do that in your Windows App SDK apps. If you install the Northwind sample database onto your SQL Server instance, and then use these snippets, you'll end up with a basic UI that shows products from the Northwind sample database.

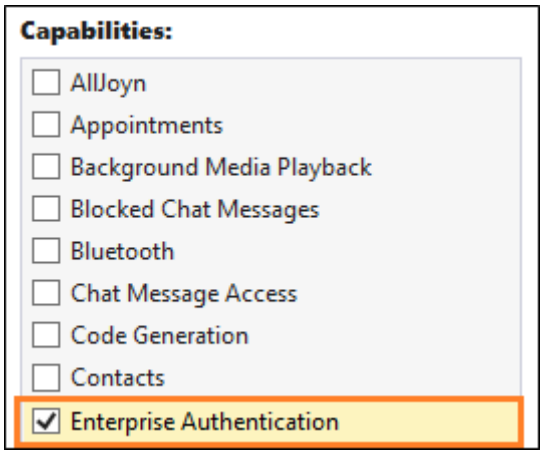
> **Tip**
>
> You can also get scripts to create the **Northwind** and **pubs** sample databases from the SQL Server Samples GitHub repository.

The snippets that appear in this guide are based on this UWP sample app.

First, set up your solution

To connect your app directly to a SQL Server database, your app can target any minimum version of Windows supported by Windows App SDK. You can find that information in the properties page of your project.

1. Open the **Package.appxmanifest** file of your Windows App SDK project in the manifest designer.
2. In the **Capabilities** tab, select the **Enterprise Authentication** checkbox if you are using Windows Authentication for authenticating your SQL Server.



> **ⓘ Important**
>
> You will also need to select **Internet (Client & Server)**, **Internet (Client)**, and **Private Networks (Client & Server)**, regardless of whether or not you're using Windows Authentication.

Add and retrieve data in a SQL Server database

In this section, we'll do these things:

[1] Add a connection string.

[2] Create a class to hold product data.

[3] Retrieve products from the SQL Server database.

[4] Add a basic user interface.

[5] Populate the UI with Products.

> **ⓘ Note**
>
> This section illustrates one way to organize your data access code. It's meant only to provide an example of how you can use System.Data.SqlClient to store and retrieve data from a SQL Server database. You can organize your code in any way that makes the most sense to your application's design.

Add a connection string

In the **App.xaml.cs** file, add a property to the `App` class, that gives other classes in your solution access to the connection string.

Our connection string points to the Northwind database in a SQL Server Express instance. The connection string in this snippet assumes you kept the default instance name `SQLEXPRESS` when installing SQL Server Express. You can make changes to the connection string to match your SQL Server instance, database, and authentication method.

C#

```
sealed partial class App : Application
{
    // Connection string for using Windows Authentication.
    private string connectionString =
        @"Data Source=.\SQLEXPRESS;Initial Catalog=NORTHWIND;Integrated
Security=SSPI";

    public string ConnectionString { get => connectionString; set =>
connectionString = value; }

    ...
}
```

> **ⓘ Important**
>
> In production applications, connection information should be stored securely in app configuration (see Adding Azure App Configuration by using Visual Studio Connected Services). Connection strings and other secrets should never be hard-coded.

Create a class to hold product data

We'll create a class that implements the INotifyPropertyChanged event so that we can bind attributes in our XAML UI to the properties in this class.

C#

```
public class Product : INotifyPropertyChanged
{
    public int ProductID { get; set; }
    public string ProductCode { get { return ProductID.ToString(); } }
    public string ProductName { get; set; }
```

```
    public string QuantityPerUnit { get; set; }
    public decimal UnitPrice { get; set; }
    public string UnitPriceString { get { return
UnitPrice.ToString("######.00"); } }
    public int UnitsInStock { get; set; }
    public string UnitsInStockString { get { return
UnitsInStock.ToString("#####0"); } }
    public int CategoryId { get; set; }

    public event PropertyChangedEventHandler PropertyChanged;
    private void NotifyPropertyChanged(string propertyName)
    {
        PropertyChanged?.Invoke(this, new
PropertyChangedEventArgs(propertyName));
    }
}
```

Retrieve products from the SQL Server database

In the **MainWindow.xaml.cs** file of the Windows App SDK project, create a method that gets products from the Northwind sample database, and then returns them as an ObservableCollection collection of `Product` instances.

C#

```
public ObservableCollection<Product> GetProducts(string connectionString)
{
    const string GetProductsQuery = "select ProductID, ProductName,
QuantityPerUnit," +
       " UnitPrice, UnitsInStock, Products.CategoryID " +
       " from Products inner join Categories on Products.CategoryID =
Categories.CategoryID " +
       " where Discontinued = 0";

    var products = new ObservableCollection<Product>();
    try
    {
        using (var conn = new SqlConnection(connectionString))
        {
            conn.Open();
            if (conn.State == System.Data.ConnectionState.Open)
            {
                using (SqlCommand cmd = conn.CreateCommand())
                {
                    cmd.CommandText = GetProductsQuery;
                    using (SqlDataReader reader = cmd.ExecuteReader())
                    {
                        while (reader.Read())
                        {
                            var product = new Product();
                            product.ProductID = reader.GetInt32(0);
```

```
                            product.ProductName = reader.GetString(1);
                            product.QuantityPerUnit = reader.GetString(2);
                            product.UnitPrice = reader.GetDecimal(3);
                            product.UnitsInStock = reader.GetInt16(4);
                            product.CategoryId = reader.GetInt32(5);
                            products.Add(product);
                        }
                    }
                }
            }
        }
        return products;
    }
    catch (Exception eSql)
    {
        Debug.WriteLine($"Exception: {eSql.Message}");
    }
    return null;
}
```

Add a basic user interface

Add the following XAML to the **MainWindow.xaml** file of the Windows App SDK project.

This XAML creates a ListView to show each product that you returned in the previous snippet, and binds the attributes of each row in the `ListView` to the properties that we defined in the `Product` class.

XML

```
<Grid Background="{ThemeResource SystemControlAcrylicWindowBrush}">
    <RelativePanel>
        <ListView Name="InventoryList"
                  SelectionMode="Single"
                  ScrollViewer.VerticalScrollBarVisibility="Auto"
                  ScrollViewer.IsVerticalRailEnabled="True"
                  ScrollViewer.VerticalScrollMode="Enabled"
                  ScrollViewer.HorizontalScrollMode="Enabled"
                  ScrollViewer.HorizontalScrollBarVisibility="Auto"
                  ScrollViewer.IsHorizontalRailEnabled="True"
                  Margin="20">
            <ListView.HeaderTemplate>
                <DataTemplate>
                    <StackPanel Orientation="Horizontal"  >
                        <TextBlock Text="ID" Margin="8,0" Width="50"
Foreground="DarkRed" />
                        <TextBlock Text="Product description" Width="300"
Foreground="DarkRed" />
                        <TextBlock Text="Packaging" Width="200"
Foreground="DarkRed" />
                        <TextBlock Text="Price" Width="80"
```

```
Foreground="DarkRed" />
                        <TextBlock Text="In stock" Width="80"
Foreground="DarkRed" />
                    </StackPanel>
                </DataTemplate>
            </ListView.HeaderTemplate>
            <ListView.ItemTemplate>
                <DataTemplate x:DataType="local:Product">
                    <StackPanel Orientation="Horizontal" >
                        <TextBlock Name="ItemId"
                                   Text="{x:Bind ProductCode}"
                                   Width="50" />
                        <TextBlock Name="ItemName"
                                   Text="{x:Bind ProductName}"
                                   Width="300" />
                        <TextBlock Text="{x:Bind QuantityPerUnit}"
                                   Width="200" />
                        <TextBlock Text="{x:Bind UnitPriceString}"
                                   Width="80" />
                        <TextBlock Text="{x:Bind UnitsInStockString}"
                                   Width="80" />
                    </StackPanel>
                </DataTemplate>
            </ListView.ItemTemplate>
        </ListView>
    </RelativePanel>
</Grid>
```

Show products in the ListView

Open the **MainWindow.xaml.cs** file, and add code to the constructor of the `MainWindow` class that sets the **ItemSource** property of the ListView to the ObservableCollection of `Product` instances.

C#

```
public MainWindow()
{
    this.InitializeComponent();
    InventoryList.ItemsSource = GetProducts((App.Current as
App).ConnectionString);
}
```

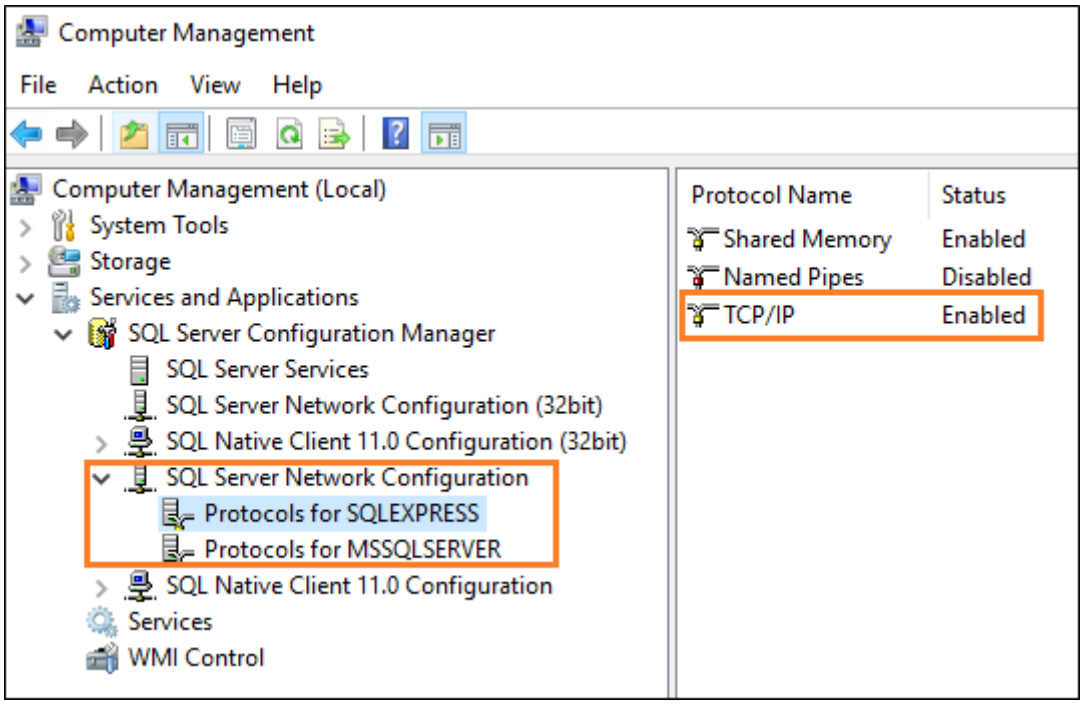
Start the project and see products from the Northwind sample database appear in the UI.

Explore the System.Data.SqlClient namespace to see what other things you can do with data in your SQL Server database.

> **Tip**
>
> Try asking **Microsoft Copilot** for help with your SQL queries. Copilot can help you write SQL queries, and suggest ways to improve your code.

Trouble connecting to your database?

In most cases, some aspect of the SQL Server configuration needs to be changed. If you're able to connect to your database from another type of desktop application such as a Windows Forms or WPF application, ensure that you've enabled TCP/IP for SQL Server. You can do that in the **Computer Management** console. (See Windows Tools/Administrative Tools for more information.)



Then, make sure that your SQL Server Browser service is running.

Use a SQLite database in a Windows app

Use a Cosmos DB database from a Windows app

Article • 08/01/2024

This article contains the steps required to enable working with a Cosmos DB database from a Windows app. It also contains a small code snippet showing how you can interact with the database in code.

Set up your solution

This example can be used with any WPF, Windows Forms, WinUI 3, and UWP project to connect your Windows app to a Cosmos DB database. Follow these steps to install the package and try out example code for some basic tasks.

1. Open the **Package Manager Console** (View -> Other Windows -> Package Manager Console). Use the command `Install-Package Microsoft.Azure.Cosmos` to install the NuGet package for the **Azure Cosmos DB for NoSQL client library for .NET**. This will allow you to programmatically access Cosmos DB databases.
2. Build your project and make sure that the build was successful with no errors.

Next, you'll need to create a Cosmos DB instance in Azure. You can do this by following the steps in Create a NoSQL database account in Azure Cosmos DB.

Work with Cosmos DB using sample code

The following sample code gets a container from a Cosmos DB instance in Azure, then adds a new item to that container. Then it uses Cosmos DB's NoSQL query API to retrieve the item from the container and output the response status. Note that the endpoint, auth key, and database name will need to be customized based on the Cosmos DB instance you created in the previous section.

> **Note**
>
> For a complete example, including information about required Cosmos DB setup and configuration, see **Develop a .NET console application with Azure Cosmos DB for NoSQL**.

C#

```
using Microsoft.Azure.Cosmos;

...

public async Task CosmosSample(string endpoint, string authKey)
{
    // CONNECT
    var client = new CosmosClient(
        accountEndpoint: endpoint,
        authKeyOrResourceToken: authKey
    );
    Database database = client.GetDatabase("sample_customers");
    ContainerProperties properties = new(
        id: "customers",
        partitionKeyPath: "/location"
    );
    Container container = await
database.CreateContainerIfNotExistsAsync(properties);

    // WRITE DATA
    string customerId = "1234";
    string state = "WA";
    var customer = new
    {
        id = customerId,
        name = "John Doe",
        location = state
    };
    var createResponse = await container.CreateItemAsync(customer);
    Console.WriteLine($"[Status code:
{createResponse.StatusCode}]\t{customerId}");

    // READ DATA
    string sql = "SELECT * FROM customers c WHERE c.id = @id";
    var query = new QueryDefinition(
        query: sql
    ).WithParameter("@id", customerId);
    using var feed = container.GetItemQueryIterator<dynamic>
(queryDefinition: query);
    var queryResponse = await feed.ReadNextAsync();
    Console.WriteLine($"[Status code:
{queryResponse.StatusCode}]\t{customerId}");
}
```

Use a MySQL database in a Windows app

Article • 02/04/2025

This article contains the steps required to enable working with a MySQL database from a Windows app. It also contains a small code snippet showing how you can interact with the database in code.

> **Tip**
>
> You can use AI assistance to create a MySQL connection string with GitHub Copilot.

Set up your solution

This example can be used with any WPF, Windows Forms, WinUI 3, and UWP project to connect your Windows app to a MySQL database. Follow these steps to install the package and try out the example code to read data from an existing MySQL database.

1. Open the **Package Manager Console** (View -> Other Windows -> Package Manager Console).
2. Use the command `Install-Package MySql.Data` to install the NuGet package for the MySQL core class library.

This will allow you to programmatically access MySQL databases.

> **Note**
>
> MySQL Connector/NET version 6.4.4 or later is required to use the `MySql.Data` package with Windows authentication.

Test your connection using sample code

The following is an example of connecting to and reading from a remote MySQL database. Note that the server address and database name will need to be customized.

```
C#
```

```
const string M_str_sqlcon =
"Server=myServerAddress;Database=myDataBase;IntegratedSecurity=yes;Uid=auth_
windows;";
using (var mySqlCn = new MySqlConnection(M_str_sqlcon))
{
    using (var mySqlCmd = new MySqlCommand("select * from table1", mySqlCn))
    {
        mySqlCn.Open();
        using (MySqlDataReader mySqlReader =
mySqlCmd.ExecuteReader(CommandBehavior.CloseConnection))
        {
            while (mySqlReader.Read())
            {
                Debug.WriteLine($"{mySqlReader.GetString(0)}:
{mySqlReader.GetString(1)}");
            }
        }
    }
}
```

> **ⓘ Important**
>
> In production applications, connection information should be stored securely in app configuration (see Adding Azure App Configuration by using Visual Studio Connected Services). Connection strings and other secrets should not be hard-coded.

Building a connection string with GitHub Copilot

You can use GitHub Copilot to build the connection string for your MySQL database. You can customize the prompt to create a connection string per your requirements.

The following text shows an example prompt for Copilot Chat that generates a connection string similar to the one shown in the previous code snippet:

Copilot prompt

```
Show me how to create a MySQL connection string to a server named
myServerAddress and a database called myDatabase. Use Windows
authentication.
```

GitHub Copilot is powered by AI, so surprises and mistakes are possible. For more information, see Copilot FAQs.

Use a MongoDB database in a Windows app

Article • 08/02/2024

This article contains the steps required to enable working with a MongoDB database from a Windows app. It also contains a small code snippet showing how you can interact with the database in code.

Set up your solution

This example can be used with any WPF, Windows Forms, WinUI 3, and UWP project to connect your Windows app to MongoDB. Follow these steps to install the package and try out the example code to read data from an existing MongoDB database.

1. Open the **Package Manager Console** (View -> Other Windows -> Package Manager Console).
2. Use the command `Install-Package MongoDB.Driver` to install the NuGet package for the official driver for MongoDB.

This will allow you to programmatically access MongoDB databases.

Test your connection using sample code

The following sample code gets a collection from a remote MongoDB client, then adds a new document to that collection. Then it uses MongoDB APIs to retrieve the new size of the collection as well as the inserted document, and prints them out.

C#

```
var client = new MongoClient("mongodb://10.xxx.xx.xxx:27017");
IMongoDatabase database = client.GetDatabase("foo");
IMongoCollection<BsonDocument> collection =
database.GetCollection<BsonDocument>("bar");
var document = new BsonDocument
{
     { "name","MongoDB"},
     { "type","Database"},
     { "count",1},
     { "info",new BsonDocument { { "x", 203 }, { "y", 102 } }}
};
collection.InsertOne(document);
long count = collection.CountDocuments(document);
Console.WriteLine(count);
```

```
IFindFluent<BsonDocument, BsonDocument> document1 =
collection.Find(document);
Console.WriteLine(document1.ToString());
```

Note that the IP address and database name will need to be customized. The port, 27017, is the default MongoDB port number. In a production application, connection information such as server address and database name should be stored in app configuration rather than hard-coded (see **Adding Azure App Configuration by using Visual Studio Connected Services**).

Data binding in Windows apps

Article • 05/17/2024

Data binding is a way for your app's UI to display data, and optionally to stay in sync with that data. Data binding allows you to create a separation of concerns between your data and UI, and that results in a simpler conceptual model as well as better readability, testability, and maintainability of your app. In XAML markup, you can choose to use either the {x:Bind} markup extension or the {Binding} markup extension. And you can even use a mixture of the two in the same app—even on the same UI element. `{x:Bind}` was new for UWP in Windows 10, is also available in Windows App SDK, and it has better performance.

Expand table

Topic	Description
Data binding overview	This topic shows you how to bind a control (or other UI element) to a single item or bind an items control to a collection of items in a Windows App SDK app. In addition, we show how to control the rendering of items, implement a details view based on a selection, and convert data for display. For more detailed info, see Data binding in depth.
Data binding in depth	This topic describes data binding features in detail.
Bind hierarchical data and create a master/details view	You can make a multi-level master/details (also known as list-details) view of hierarchical data by binding items controls to **CollectionViewSource** instances that are bound together in a chain.
Data binding and MVVM	This topic describes the Model-View-ViewModel (MVVM) UI architectural design pattern. Data binding is at the core of MVVM, and enables loose coupling between UI and non-UI code.
Functions in x:Bind	In Windows App SDK apps, `{x:Bind}` supports using a function as the leaf step of the binding path. In this topic, learn how properties are bound to functions to do conversions, date formatting, text formatting, text concatenations, etc.

Windows data binding overview

Article • 01/10/2025

This topic shows you how to bind a control (or other UI element) to a single item or bind an items control to a collection of items in a Windows App SDK app. In addition, we show how to control the rendering of items, implement a details view based on a selection, and convert data for display. For more detailed info, see Data binding in depth.

Prerequisites

This topic assumes that you know how to create a basic Windows App SDK app. For instructions on creating your first Windows App SDK app, see Create your first WinUI 3 (Windows App SDK) project.

Create the project

Create a new **Blank App, Packaged (WinUI 3 in Desktop)** C# project. Name it "Quickstart".

Binding to a single item

Every binding consists of a binding target and a binding source. Typically, the target is a property of a control or other UI element, and the source is a property of a class instance (a data model, or a view model). This example shows how to bind a control to a single item. The target is the `Text` property of a `TextBlock`. The source is an instance of a simple class named `Recording` that represents an audio recording. Let's look at the class first.

Add a new class to your project, and name the class `Recording`.

C#

```
namespace Quickstart
{
    public class Recording
    {
        public string ArtistName { get; set; }
        public string CompositionName { get; set; }
        public DateTime ReleaseDateTime { get; set; }
        public Recording()
```

```
        {
            ArtistName = "Wolfgang Amadeus Mozart";
            CompositionName = "Andante in C for Piano";
            ReleaseDateTime = new DateTime(1761, 1, 1);
        }
        public string OneLineSummary
        {
            get
            {
                return $"{CompositionName} by {ArtistName}, released: "
                    + ReleaseDateTime.ToString("d");
            }
        }
    }
    public class RecordingViewModel
    {
        private Recording defaultRecording = new Recording();
        public Recording DefaultRecording { get { return defaultRecording; }
}
    }
}
```

Next, expose the binding source class from the class that represents your window of markup. We do that by adding a property of type `RecordingViewModel` to **MainWindow.xaml.cs**.

C#

```
namespace Quickstart
{
    public sealed partial class MainWindow : Window
    {
        public MainWindow()
        {
            this.InitializeComponent();
            ViewModel = new RecordingViewModel();
        }
        public RecordingViewModel ViewModel{ get; set; }
    }
}
```

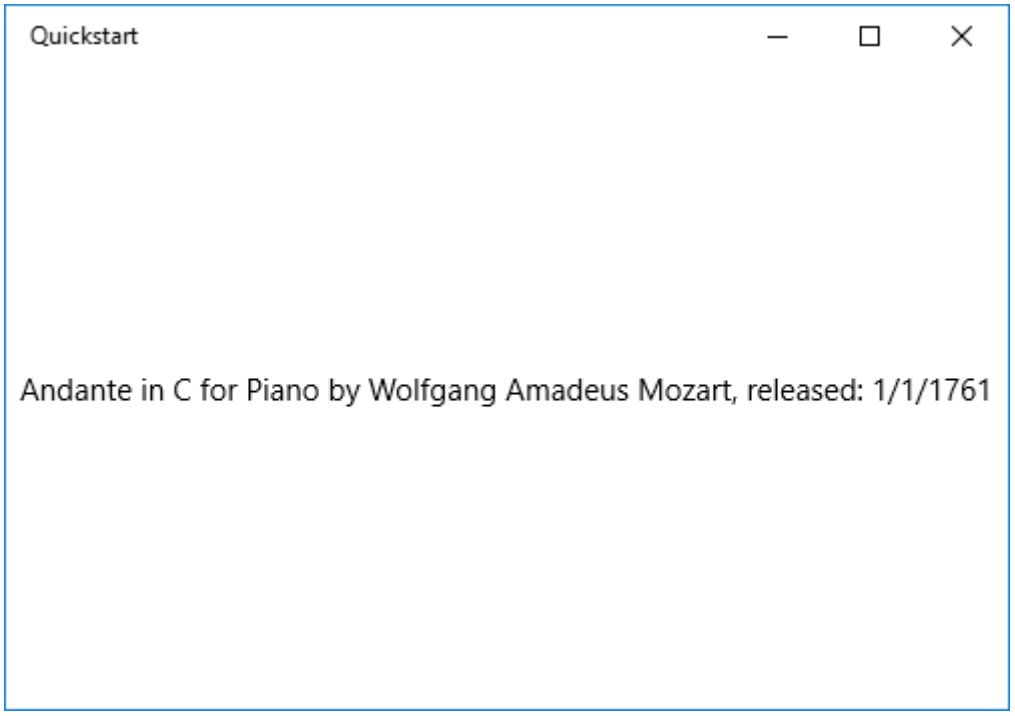
The last piece is to bind a `TextBlock` to the `ViewModel.DefaultRecording.OneLineSummary` property.

XAML

```
<Window x:Class="Quickstart.MainWindow" ... >
    <Grid>
        <TextBlock Text="{x:Bind ViewModel.DefaultRecording.OneLineSummary}"
    HorizontalAlignment="Center"
```

```
    VerticalAlignment="Center"/>
    </Grid>
</Window>
```

Here's the result.



Binding to a collection of items

A common scenario is to bind to a collection of business objects. In C#, the generic ObservableCollection<T> class is a good collection choice for data binding, because it implements the INotifyPropertyChanged and INotifyCollectionChanged interfaces. These interfaces provide change notification to bindings when items are added or removed or a property of the list itself changes. If you want your bound controls to update with changes to properties of objects in the collection, the business object should also implement `INotifyPropertyChanged`. For more info, see Data binding in depth.

This next example binds a ListView to a collection of `Recording` objects. Let's start by adding the collection to our view model. Just add these new members to the `RecordingViewModel` class.

C#

```
public class RecordingViewModel
{
    ...
    private ObservableCollection<Recording> recordings = new
ObservableCollection<Recording>();
    public ObservableCollection<Recording> Recordings{ get{ return
```

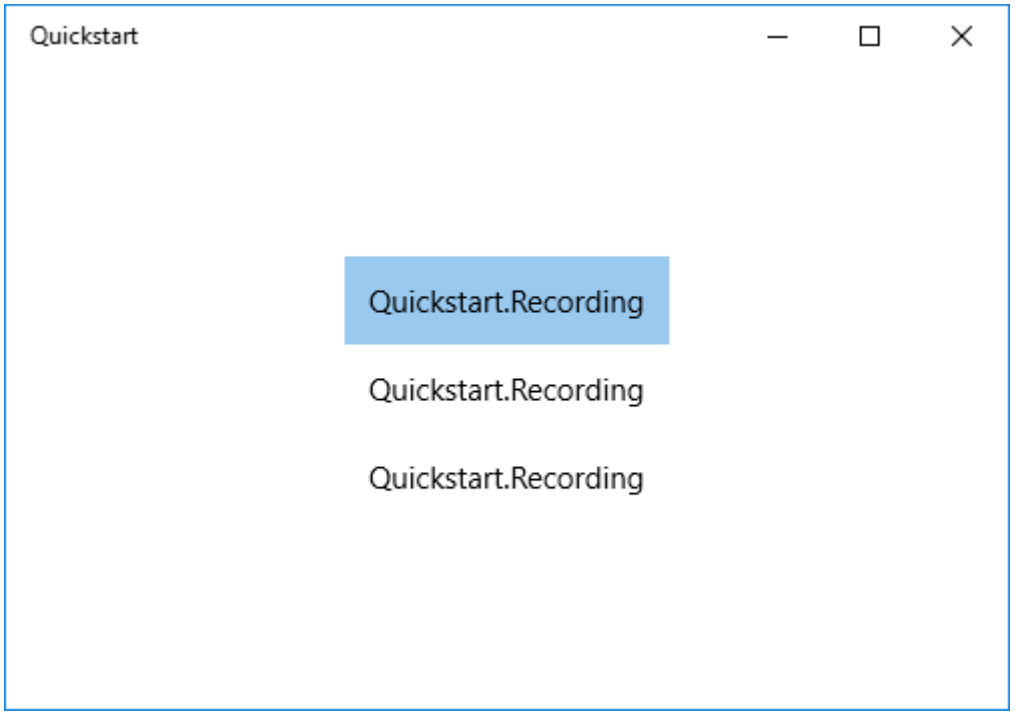
```
recordings; } }
    public RecordingViewModel()
    {
        recordings.Add(new Recording(){ ArtistName = "Johann Sebastian
Bach",
            CompositionName = "Mass in B minor", ReleaseDateTime = new
DateTime(1748, 7, 8) });
        recordings.Add(new Recording(){ ArtistName = "Ludwig van Beethoven",
            CompositionName = "Third Symphony", ReleaseDateTime = new
DateTime(1805, 2, 11) });
        recordings.Add(new Recording(){ ArtistName = "George Frideric
Handel",
            CompositionName = "Serse", ReleaseDateTime = new DateTime(1737,
12, 3) });
    }
}
```

And then bind a ListView to the `ViewModel.Recordings` property.

XAML

```
<Window x:Class="Quickstart.MainWindow" ... >
    <Grid>
        <ListView ItemsSource="{x:Bind ViewModel.Recordings}"
        HorizontalAlignment="Center" VerticalAlignment="Center"/>
    </Grid>
</Window>
```

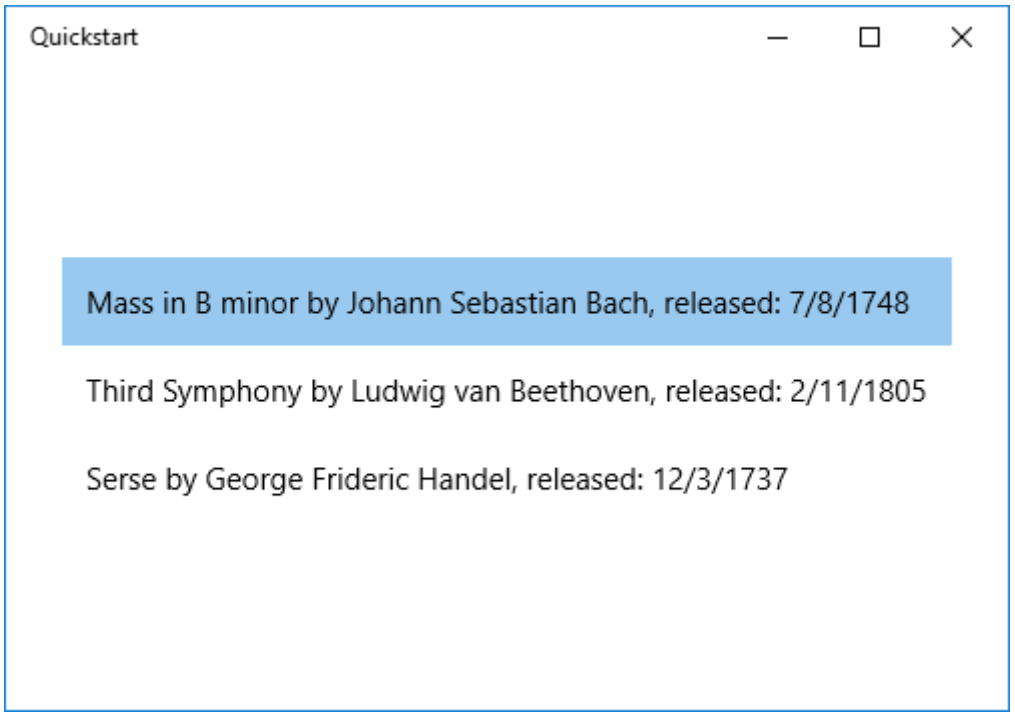
We haven't yet provided a data template for the `Recording` class, so the best the UI framework can do is to call ToString for each item in the ListView. The default implementation of `ToString` is to return the type name.



To remedy this, we can either override ToString to return the value of `OneLineSummary`, or we can provide a data template. The data template option is a more usual solution, and a more flexible one. You specify a data template by using the ContentTemplate property of a content control or the ItemTemplate property of an items control. Here are two ways we could design a data template for `Recording` together with an illustration of the result.

XAML

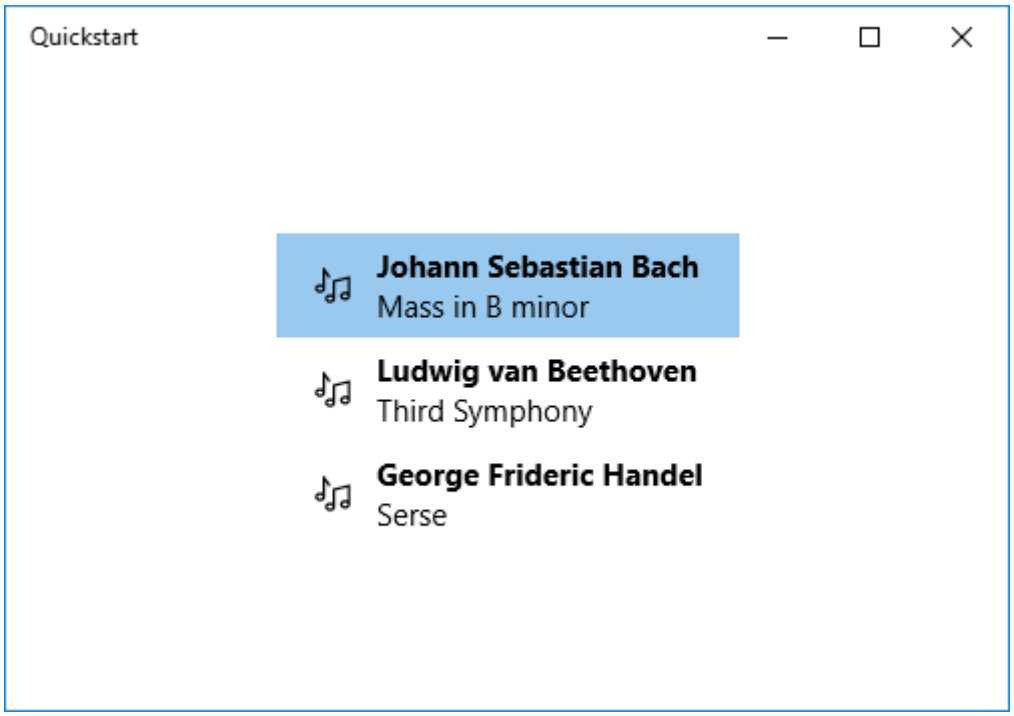
```
<ListView ItemsSource="{x:Bind ViewModel.Recordings}"
HorizontalAlignment="Center" VerticalAlignment="Center">
    <ListView.ItemTemplate>
        <DataTemplate x:DataType="local:Recording">
            <TextBlock Text="{x:Bind OneLineSummary}"/>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```



XAML

```
<ListView ItemsSource="{x:Bind ViewModel.Recordings}"
HorizontalAlignment="Center" VerticalAlignment="Center">
    <ListView.ItemTemplate>
        <DataTemplate x:DataType="local:Recording">
            <StackPanel Orientation="Horizontal" Margin="6">
                <SymbolIcon Symbol="Audio" Margin="0,0,12,0"/>
                <StackPanel>
                    <TextBlock Text="{x:Bind ArtistName}"
FontWeight="Bold"/>
                    <TextBlock Text="{x:Bind CompositionName}"/>
                </StackPanel>
```

```
            </StackPanel>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```



For more information about XAML syntax, see Create a UI with XAML. For more information about control layout, see Define layouts with XAML.

Adding a details view

You can choose to display all the details of `Recording` objects in ListView items. But that takes up a lot of space. Instead, you can show just enough data in the item to identify it and then, when the user makes a selection, you can display all the details of the selected item in a separate piece of UI known as the details view. This arrangement is also known as a master/details view, or a list/details view.

There are two ways to go about this. You can bind the details view to the SelectedItem property of the ListView. Or you can use a CollectionViewSource, in which case you bind both the `ListView` and the details view to the `CollectionViewSource` (doing so takes care of the currently-selected item for you). Both techniques are shown below, and they both give the same results (shown in the illustration).

> ⓘ **Note**

So far in this topic we've only used the {x:Bind} markup extension, but both of the techniques we'll show below require the more flexible (but less performant) {Binding} markup extension.

First, here's the SelectedItem technique. For a C# application, the only change necessary is to the markup.

XAML

```
<Window x:Class="Quickstart.MainWindow" ... >
    <Grid>
        <StackPanel HorizontalAlignment="Center" VerticalAlignment="Center">
            <ListView x:Name="recordingsListView" ItemsSource="{x:Bind
ViewModel.Recordings}">
                <ListView.ItemTemplate>
                    <DataTemplate x:DataType="local:Recording">
                        <StackPanel Orientation="Horizontal" Margin="6">
                            <SymbolIcon Symbol="Audio" Margin="0,0,12,0"/>
                            <StackPanel>
                                <TextBlock Text="{x:Bind CompositionName}"/>
                            </StackPanel>
                        </StackPanel>
                    </DataTemplate>
                </ListView.ItemTemplate>
            </ListView>
            <StackPanel DataContext="{Binding SelectedItem,
ElementName=recordingsListView}"
            Margin="0,24,0,0">
                <TextBlock Text="{Binding ArtistName}"/>
                <TextBlock Text="{Binding CompositionName}"/>
                <TextBlock Text="{Binding ReleaseDateTime}"/>
            </StackPanel>
        </StackPanel>
    </Grid>
</Window>
```

For the CollectionViewSource technique, first add a `CollectionViewSource` as a resource of the top-level `Grid`.

XAML

```
<Grid.Resources>
    <CollectionViewSource x:Name="RecordingsCollection" Source="{x:Bind
ViewModel.Recordings}"/>
</Grid.Resources>
```

ⓘ Note

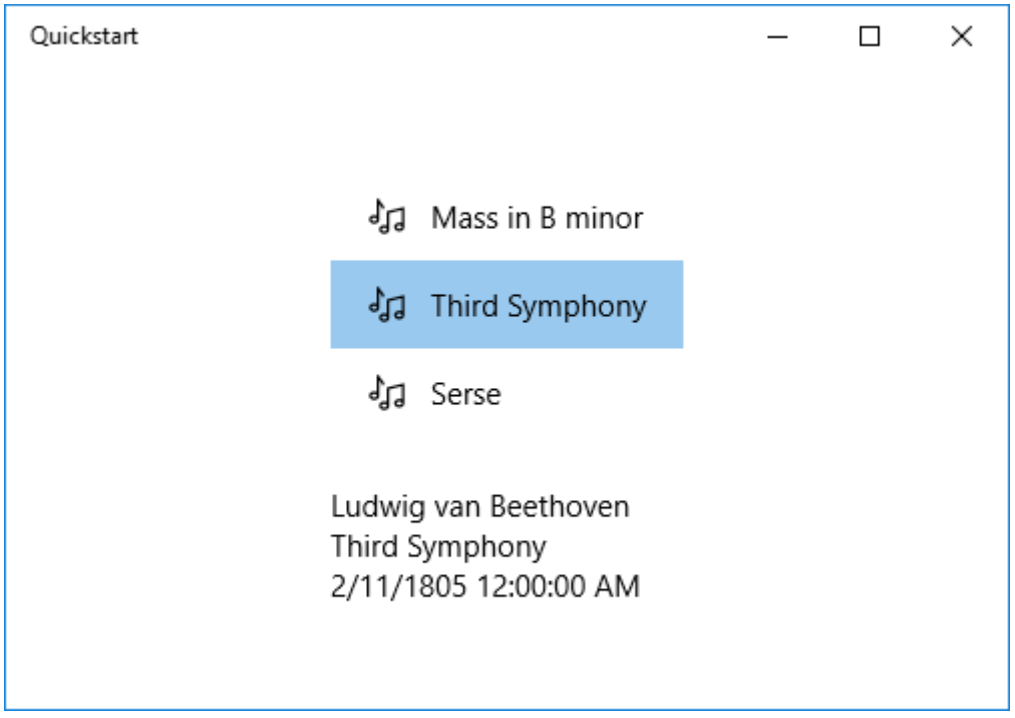
The Window class in WinUI doesn't have a `Resources` property. You can add the `CollectionViewSource` to the top-level `Grid` (or other parent UI element like `StackPanel`) element instead. If you're working within a `Page`, you can add the `CollectionViewSource` to the `Page.Resources`.

And then adjust the bindings on the ListView (which no longer needs to be named) and on the details view to use the CollectionViewSource. Note that by binding the details view directly to the `CollectionViewSource`, you're implying that you want to bind to the current item in bindings where the path cannot be found on the collection itself. There's no need to specify the `CurrentItem` property as the path for the binding, although you can do that if there's any ambiguity.

XAML

```
...
<ListView ItemsSource="{Binding Source={StaticResource
RecordingsCollection}}">
...
<StackPanel DataContext="{Binding Source={StaticResource
RecordingsCollection}}" ...>
...
```

And here's the identical result in each case.



Formatting or converting data values for display

There is an issue with the rendering above. The `ReleaseDateTime` property is not just a date, it's a DateTime. So, it's being displayed with more precision than we need. One solution is to add a string property to the `Recording` class that returns the equivalent of `ReleaseDateTime.ToString("d")`. Naming that property `ReleaseDate` would indicate that it returns a date, and not a date-and-time. Naming it `ReleaseDateAsString` would further indicate that it returns a string.

A more flexible solution is to use something known as a value converter. Here's an example of how to author your own value converter. Add the code below to your **Recording.cs** source code file.

C#

```
public class StringFormatter : Microsoft.UI.Xaml.Data.IValueConverter
{
    // This converts the value object to the string to display.
    // This will work with most simple types.
    public object Convert(object value, Type targetType,
        object parameter, string language)
    {
        // Retrieve the format string and use it to format the value.
        string formatString = parameter as string;
        if (!string.IsNullOrEmpty(formatString))
        {
            return string.Format(formatString, value);
        }

        // If the format string is null or empty, simply
        // call ToString() on the value.
        return value.ToString();
    }

    // No need to implement converting back on a one-way binding
    public object ConvertBack(object value, Type targetType,
        object parameter, string language)
    {
        throw new NotImplementedException();
    }
}
```

Now we can add an instance of `StringFormatter` as a resource and use it in the binding of the `TextBlock` that displays the `ReleaseDateTime` property.

XAML

```
<Grid.Resources>
    ...
    <local:StringFormatter x:Key="StringFormatterValueConverter"/>
</Grid.Resources>
```

```
...
<TextBlock Text="{Binding ReleaseDateTime,
    Converter={StaticResource StringFormatterValueConverter},
    ConverterParameter=Released: \{0:d\}}"/>
...
```

As you can see above, for formatting flexibility we use the markup to pass a format string into the converter by way of the converter parameter. In the code example shown in this topic, the C# value converter makes use of that parameter.

Here's the result.

Windows data binding in depth

Article • 06/16/2023

In this article, we will describe the Windows App SDK data binding features for the APIs that reside in the **Microsoft.UI.Xaml.Data** namespace.

> **Note**
>
> This topic describes data binding features in detail. For a short, practical introduction, see **Data binding overview**.

Important APIs

- **{x:Bind} markup extension**
- **Binding class**
- **DataContext**
- **INotifyPropertyChanged**

Introduction

Data binding is a way for your app's UI to display data, and optionally to stay in sync with that data. Data binding allows you to separate the concern of data from the concern of UI, and that results in a simpler conceptual model as well as better readability, testability, and maintainability of your app.

You can use data binding to simply display values from a data source when the UI is first shown, but not to respond to changes in those values. This is a mode of binding called *one-time*, and it works well for a value that doesn't change during run-time. Alternatively, you can choose to "observe" the values and to update the UI when they change. This mode is called *one-way*, and it works well for read-only data. Ultimately, you can choose to both observe and update, so that changes that the user makes to values in the UI are automatically pushed back into the data source. This mode is called *two-way*, and it works well for read-write data. Here are some examples.

- You could use the one-time mode to bind an **Image** to the current user's photo.
- You could use the one-way mode to bind a **ListView** to a collection of real-time news articles grouped by newspaper section.
- You could use the two-way mode to bind a **TextBox** to a customer's name in a form.

Independent of mode, there are two kinds of binding, and they're both typically declared in UI markup. You can choose to use either the {x:Bind} markup extension or the {Binding} markup extension. And you can even use a mixture of the two in the same app—even on the same UI element. `{x:Bind}` was new in UWP for Windows 10 and it has better performance. All the details described in this topic apply to both kinds of binding unless we explicitly say otherwise.

UWP Sample apps that demonstrate {x:Bind}

- Download the Bookstore2 app.

Every binding involves these pieces

- A *binding source*. This is the source of the data for the binding, and it can be an instance of any class that has members whose values you want to display in your UI.
- A *binding target*. This is a **DependencyProperty** of the **FrameworkElement** in your UI that displays the data.
- A *binding object*. This is the piece that transfers data values from the source to the target, and optionally from the target back to the source. The binding object is created at XAML load time from your {x:Bind} or {Binding} markup extension.

In the following sections, we'll take a closer look at the binding source, the binding target, and the binding object. And we'll link the sections together with the example of binding a button's content to a string property named `NextButtonText`, which belongs to a class named `HostViewModel`.

Binding source

Here's a very rudimentary implementation of a class that we could use as a binding source.

```
C#
```

```
public class HostViewModel
{
    public HostViewModel()
    {
        NextButtonText = "Next";
    }

    public string NextButtonText { get; set; }
}
```

That implementation of `HostViewModel`, and its property `NextButtonText`, are only appropriate for one-time binding. But one-way and two-way bindings are extremely common, and in those kinds of binding the UI automatically updates in response to changes in the data values of the binding source. In order for those kinds of binding to work correctly, you need to make your binding source *observable* to the binding object. So in our example, if we want to one-way or two-way bind to the `NextButtonText` property, then any changes that happen at run-time to the value of that property need to be made observable to the binding object.

One way of doing that is to derive the class that represents your binding source from **DependencyObject**, and expose a data value through a **DependencyProperty**. That's how a **FrameworkElement** becomes observable. A `FrameworkElement` is a good binding source right out of the box.

A more lightweight way of making a class observable—and a necessary one for classes that already have a base class—is to implement **System.ComponentModel.INotifyPropertyChanged**. This really just involves implementing a single event named `PropertyChanged`. An example using `HostViewModel` is below.

C#

```
...
using System.ComponentModel;
using System.Runtime.CompilerServices;
...
public class HostViewModel : INotifyPropertyChanged
{
    private string nextButtonText;

    public event PropertyChangedEventHandler PropertyChanged = delegate { };

    public HostViewModel()
    {
        NextButtonText = "Next";
    }
```

```
    public string NextButtonText
    {
        get { return nextButtonText; }
        set
        {
            nextButtonText = value;
            OnPropertyChanged();
        }
    }

    public void OnPropertyChanged([CallerMemberName] string propertyName =
null)
    {
        // Raise the PropertyChanged event, passing the name of the property
whose value has changed.
        PropertyChanged?.Invoke(this, new
PropertyChangedEventArgs(propertyName));
    }
}
```

Now the `NextButtonText` property is observable. When you author a one-way or a two-way binding to that property (we'll show how later), the resulting binding object subscribes to the `PropertyChanged` event. When that event is raised, the binding object's handler receives an argument containing the name of the property that has changed. That's how the binding object knows which property's value to go and read again.

So that you don't have to implement the pattern shown above multiple times, if you're using C# then you can just derive from the `BindableBase` base class that you'll find in the QuizGame sample (in the "Common" folder). Here's an example of how that looks.

C#

```
public class HostViewModel : BindableBase
{
    private string nextButtonText;

    public HostViewModel()
    {
        NextButtonText = "Next";
    }

    public string NextButtonText
    {
        get { return nextButtonText; }
        set { SetProperty(ref nextButtonText, value); }
    }
}
```

Raising the `PropertyChanged` event with an argument of **String.Empty** or `null` indicates that all non-indexer properties on the object should be re-read. You can raise the event to indicate that indexer properties on the object have changed by using an argument of "Item[*indexer*]" for specific indexers (where *indexer* is the index value), or a value of "Item[]" for all indexers.

A binding source can be treated either as a single object whose properties contain data, or as a collection of objects. In C# code, you can one-time bind to an object that implements **List<T>** to display a collection that doesn't change at run-time. For an observable collection (observing when items are added to and removed from the collection), one-way bind to **ObservableCollection<T>** instead. To bind to your own collection classes, use the guidance in the following table.

Scenario	C# (CLR)	C++/WinRT
Bind to an object.	Can be any object.	Can be any object.
Get property change notifications from a bound object.	Object must implement **INotifyPropertyChanged**.	Object must implement **INotifyPropertyChanged**.
Bind to a collection.	**List<T>**	**IVector** of **IInspectable**, or **IBindableObservableVector**. See XAML items controls; bind to a C++/WinRT collection and Collections with C++/WinRT.
Get collection change notifications from a bound collection.	**ObservableCollection<T>**	**IObservableVector** of **IInspectable**. For example, **winrt::single_threaded_observable_vector<T>**.
Implement a collection that supports binding.	Extend **List<T>** or implement **IList**, **IList<Object>**, **IEnumerable**, or **IEnumerable**<Object>. Binding to generic `IList<T>` and `IEnumerable<T>` is not supported.	Implement **IVector** of **IInspectable**. See XAML items controls; bind to a C++/WinRT collection and Collections with C++/WinRT.
Implement a collection	Extend **ObservableCollection<T>** or	Implement **IObservableVector** of **IInspectable**, or **IBindableObservableVector**.

Scenario	C# (CLR)	C++/WinRT
that supports collection change notifications.	implement (non-generic) IList and INotifyCollectionChanged.	
Implement a collection that supports incremental loading.	Extend ObservableCollection<T> or implement (non-generic) IList and INotifyCollectionChanged. Additionally, implement ISupportIncrementalLoading.	Implement IObservableVector of IInspectable, or IBindableObservableVector. Additionally, implement ISupportIncrementalLoading

You can bind list controls to arbitrarily large data sources, and still achieve high performance, by using incremental loading. For example, you can bind list controls to Bing image query results without having to load all the results at once. Instead, you load only some results immediately, and load additional results as needed. To support incremental loading, you must implement **ISupportIncrementalLoading** on a data source that supports collection change notifications. When the data binding engine requests more data, your data source must make the appropriate requests, integrate the results, and then send the appropriate notifications in order to update the UI.

Binding target

In the two examples below, the `Button.Content` property is the binding target, and its value is set to a markup extension that declares the binding object. First {x:Bind} is shown, and then {Binding}. Declaring bindings in markup is the common case (it's convenient, readable, and toolable). But you can avoid markup and imperatively (programmatically) create an instance of the **Binding** class instead if you need to.

XAML

```
<Button Content="{x:Bind ...}" ... />
```

XAML

```
<Button Content="{Binding ...}" ... />
```

Binding object declared using {x:Bind}

There's one step we need to do before we author our {x:Bind} markup. We need to expose our binding source class from the class that represents our page of markup. We do that by adding a property (of type `HostViewModel` in this case) to our `MainWindow` window class.

C#

```
namespace DataBindingInDepth
{
    public sealed partial class MainWindow : Window
    {
        public MainWindow()
        {
            this.InitializeComponent();
            ViewModel = new HostViewModel();
        }

        public HostViewModel ViewModel { get; set; }
    }
}
```

That done, we can now take a closer look at the markup that declares the binding object. The example below uses the same `Button.Content` binding target we used in the "Binding target" section earlier, and shows it being bound to the `HostViewModel.NextButtonText` property.

XAML

```
<!-- MainWindow.xaml -->
<Window x:Class="DataBindingInDepth.MainWindow" ... >
    <Button Content="{x:Bind Path=ViewModel.NextButtonText, Mode=OneWay}"
... />
</Window>
```

Notice the value that we specify for `Path`. This value is interpreted in the context of the window itself, and in this case the path begins by referencing the `ViewModel` property that we just added to the `MainWindow` page. That property returns a `HostViewModel` instance, and so we can *dot* into that object to access the `HostViewModel.NextButtonText` property. And we specify `Mode`, to override the {x:Bind} default of one-time.

The **Path** property supports a variety of syntax options for binding to nested properties, attached properties, and integer and string indexers. For more info, see Property-path syntax. Binding to string indexers gives you the effect of binding to dynamic properties without having to implement **ICustomPropertyProvider**. For other settings, see {x:Bind} markup extension.

To illustrate that the `HostViewModel.NextButtonText` property is indeed observable, add a `Click` event handler to the button, and update the value of `HostViewModel.NextButtonText`. Build, run, and click the button to see the value of the button's `Content` update.

C#

```
// MainWindow.xaml.cs
private void Button_Click(object sender, RoutedEventArgs e)
{
    ViewModel.NextButtonText = "Updated Next button text";
}
```

> ⓘ Note
>
> Changes to **TextBox.Text** are sent to a two-way bound source when the **TextBox** loses focus, and not after every user keystroke.

DataTemplate and x:DataType

Inside a **DataTemplate** (whether used as an item template, a content template, or a header template), the value of `Path` is not interpreted in the context of the window, but in the context of the data object being templated. When using `{x:Bind}` in a data template, so that its bindings can be validated (and efficient code generated for them) at compile-time, the `DataTemplate` needs to declare the type of its data object using `x:DataType`. The example given below could be used as the `ItemTemplate` of an items control bound to a collection of `SampleDataGroup` objects.

XAML

```
<DataTemplate x:Key="SimpleItemTemplate" x:DataType="data:SampleDataGroup">
    <StackPanel Orientation="Vertical" Height="50">
      <TextBlock Text="{x:Bind Title}"/>
      <TextBlock Text="{x:Bind Description}"/>
    </StackPanel>
  </DataTemplate>
```

Weakly-typed objects in your Path

Consider for example that you have a type named `SampleDataGroup`, which implements a string property named `Title`. And you have a property

`MainWindow.SampleDataGroupAsObject`, which is of type `object`, but which actually returns an instance of `SampleDataGroup`. The binding `<TextBlock Text="{x:Bind SampleDataGroupAsObject.Title}"/>` will result in a compile error because the `Title` property is not found on the type `object`. The remedy for this is to add a cast to your `Path` syntax like this: `<TextBlock Text="{x:Bind ((data:SampleDataGroup)SampleDataGroupAsObject).Title}"/>`. Here's another example where `Element` is declared as `object` but is actually a `TextBlock`: `<TextBlock Text="{x:Bind Element.Text}"/>`. And a cast remedies the issue: `<TextBlock Text="{x:Bind ((TextBlock)Element).Text}"/>`.

If your data loads asynchronously

Code to support `{x:Bind}` is generated at compile-time in the partial classes for your windows. These files can be found in your `obj` folder, with names like (for C#) `<view name>.g.cs`. The generated code includes a handler for your window's **Loading** event, and that handler calls the `Initialize` method on a generated class that represent's your window's bindings. `Initialize` in turn calls `Update` to begin moving data between the binding source and the target. `Loading` is raised just before the first measure pass of the window or user control. So if your data is loaded asynchronously it may not be ready by the time `Initialize` is called. So, after you've loaded data, you can force one-time bindings to be initialized by calling `this.Bindings.Update();`. If you only need one-time bindings for asynchronously-loaded data then it's much cheaper to initialize them this way than it is to have one-way bindings and to listen for changes. If your data does not undergo fine-grained changes, and if it's likely to be updated as part of a specific action, then you can make your bindings one-time, and force a manual update at any time with a call to `Update`.

> ⓘ **Note**
>
> `{x:Bind}` is not suited to late-bound scenarios, such as navigating the dictionary structure of a JSON object, nor duck typing. "Duck typing" is a weak form of typing based on lexical matches on property names (as in, "if it walks, swims, and quacks like a duck, then it's a duck"). With duck typing, a binding to the `Age` property would be equally satisfied with a `Person` or a `Wine` object (assuming that those types each had an `Age` property). For these scenarios, use the `{Binding}` markup extension.

Binding object declared using {Binding}

{Binding} assumes, by default, that you're binding to the **DataContext** of your markup window. So we'll set the `DataContext` of our window to be an instance of our binding source class (of type `HostViewModel` in this case). The example below shows the markup that declares the binding object. We use the same `Button.Content` binding target we used in the "Binding target" section earlier, and we bind to the `HostViewModel.NextButtonText` property.

XAML

```
<Window xmlns:viewmodel="using:DataBindingInDepth" ... >
    <Window.DataContext>
        <viewmodel:HostViewModel x:Name="viewModelInDataContext"/>
    </Window.DataContext>
    ...
    <Button Content="{Binding Path=NextButtonText}" ... />
</Window>
```

C#

```
// MainWindow.xaml.cs
private void Button_Click(object sender, RoutedEventArgs e)
{
    viewModelInDataContext.NextButtonText = "Updated Next button text";
}
```

Notice the value that we specify for `Path`. This value is interpreted in the context of the window's **DataContext**, which in this example is set to an instance of `HostViewModel`. The path references the `HostViewModel.NextButtonText` property. We can omit `Mode`, because the {Binding} default of one-way works here.

The default value of **DataContext** for a UI element is the inherited value of its parent. You can of course override that default by setting `DataContext` explicitly, which is in turn inherited by children by default. Setting `DataContext` explicitly on an element is useful when you want to have multiple bindings that use the same source.

A binding object has a `Source` property, which defaults to the **DataContext** of the UI element on which the binding is declared. You can override this default by setting `Source`, `RelativeSource`, or `ElementName` explicitly on the binding (see {Binding} for details).

Inside a **DataTemplate**, the **DataContext** is automatically set to the data object being templated. The example given below could be used as the `ItemTemplate` of an items control bound to a collection of any type that has string properties named `Title` and `Description`.

XAML

```
<DataTemplate x:Key="SimpleItemTemplate">
    <StackPanel Orientation="Vertical" Height="50">
      <TextBlock Text="{Binding Title}"/>
      <TextBlock Text="{Binding Description"/>
    </StackPanel>
  </DataTemplate>
```

> **Note**
>
> By default, changes to **TextBox.Text** are sent to a two-way bound source when the **TextBox** loses focus. To cause changes to be sent after every user keystroke, set `UpdateSourceTrigger` to `PropertyChanged` on the binding in markup. You can also completely take control of when changes are sent to the source by setting `UpdateSourceTrigger` to `Explicit`. You then handle events on the text box (typically **TextBox.TextChanged**), call **GetBindingExpression** on the target to get a **BindingExpression** object, and finally call **BindingExpression.UpdateSource** to programmatically update the data source.

The **Path** property supports a variety of syntax options for binding to nested properties, attached properties, and integer and string indexers. For more info, see Property-path syntax. Binding to string indexers gives you the effect of binding to dynamic properties without having to implement **ICustomPropertyProvider**. The **ElementName** property is useful for element-to-element binding. The **RelativeSource** property has several uses, one of which is as a more powerful alternative to template binding inside a **ControlTemplate**. For other settings, see {Binding} markup extension and the **Binding** class.

What if the source and the target are not the same type?

If you want to control the visibility of a UI element based on the value of a boolean property, or if you want to render a UI element with a color that's a function of a numeric value's range or trend, or if you want to display a date and/or time value in a UI element property that expects a string, then you'll need to convert values from one type to another. There will be cases where the right solution is to expose another property of the right type from your binding source class, and keep the conversion logic encapsulated and testable there. But that isn't flexible nor scalable when you have large

numbers, or large combinations, of source and target properties. In that case you have a couple of options:

- If using `{x:Bind}` then you can bind directly to a function to do that conversion
- Or you can specify a value converter which is an object designed to perform the conversion

Value Converters

Here's a value converter, suitable for a one-time or a one-way binding, that converts a **DateTime** value to a `string` value containing the month. The class implements **IValueConverter**.

C#

```
public class DateToStringConverter : IValueConverter
{
    // Define the Convert method to convert a DateTime value to
    // a month string.
    public object Convert(object value, Type targetType,
        object parameter, string language)
    {
        // value is the data from the source object.
        DateTime thisDate = (DateTime)value;
        int monthNum = thisDate.Month;
        string month;
        switch (monthNum)
        {
            case 1:
                month = "January";
                break;
            case 2:
                month = "February";
                break;
            default:
                month = "Month not found";
                break;
        }
        // Return the value to pass to the target.
        return month;
    }

    // ConvertBack is not implemented for a OneWay binding.
    public object ConvertBack(object value, Type targetType,
        object parameter, string language)
    {
        throw new NotImplementedException();
    }
}
```

And here's how you consume that value converter in your binding object markup.

XAML

```
<UserControl.Resources>
  <local:DateToStringConverter x:Key="Converter1"/>
</UserControl.Resources>
...
<TextBlock Grid.Column="0"
  Text="{x:Bind ViewModel.Month, Converter={StaticResource Converter1}}"/>
<TextBlock Grid.Column="0"
  Text="{Binding Month, Converter={StaticResource Converter1}}"/>
```

The binding engine calls the **Convert** and **ConvertBack** methods if the **Converter** parameter is defined for the binding. When data is passed from the source, the binding engine calls `Convert` and passes the returned data to the target. When data is passed from the target (for a two-way binding), the binding engine calls `ConvertBack` and passes the returned data to the source.

The converter also has optional parameters: **ConverterLanguage**, which allows specifying the language to be used in the conversion, and **ConverterParameter**, which allows passing a parameter for the conversion logic. For an example that uses a converter parameter, see **IValueConverter**.

> ⓘ **Note**
>
> If there is an error in the conversion, do not throw an exception. Instead, return **DependencyProperty.UnsetValue**, which will stop the data transfer.

To display a default value to use whenever the binding source cannot be resolved, set the `FallbackValue` property on the binding object in markup. This is useful to handle conversion and formatting errors. It is also useful to bind to source properties that might not exist on all objects in a bound collection of heterogeneous types.

If you bind a text control to a value that is not a string, the data binding engine will convert the value to a string. If the value is a reference type, the data binding engine will retrieve the string value by calling **ICustomPropertyProvider.GetStringRepresentation** or **IStringable.ToString** if available, and will otherwise call **Object.ToString**. Note, however, that the binding engine will ignore any `ToString` implementation that hides the base-class implementation. Subclass implementations should override the base class `ToString` method instead. Similarly, in native languages, all managed objects appear to implement **ICustomPropertyProvider** and **IStringable**. However, all calls to `GetStringRepresentation` and `IStringable.ToString` are routed to `Object.ToString` or

an override of that method, and never to a new `ToString` implementation that hides the base-class implementation.

> **Note**
>
> The **Windows Community Toolkit** provides a **BoolToVisibilityConverter**. The converter maps `true` to the `Visible` enumeration value and `false` to `Collapsed` so you can bind a `Visibility` property to a boolean without creating a converter. To use the converter, your project must add the **CommunityToolkit.WinUI.Converters** NuGet package.

Function binding in {x:Bind}

`{x:Bind}` enables the final step in a binding path to be a function. This can be used to perform conversions, and to perform bindings that depend on more than one property. See **Functions in x:Bind**

Element-to-element binding

You can bind the property of one XAML element to the property of another XAML element. Here's an example of how that looks in markup.

XAML

```
<TextBox x:Name="myTextBox" />
<TextBlock Text="{x:Bind myTextBox.Text, Mode=OneWay}" />
```

Resource dictionaries with {x:Bind}

The {x:Bind} markup extension depends on code generation, so it needs a code-behind file containing a constructor that calls `InitializeComponent` (to initialize the generated code). You re-use the resource dictionary by instantiating its type (so that `InitializeComponent` is called) instead of referencing its filename. Here's an example of what to do if you have an existing resource dictionary and you want to use `{x:Bind}` in it.

XAML

```
<!-- TemplatesResourceDictionary.xaml -->
<ResourceDictionary
```

```
    x:Class="ExampleNamespace.TemplatesResourceDictionary"
    .....
    xmlns:examplenamespace="using:ExampleNamespace">

    <DataTemplate x:Key="EmployeeTemplate"
x:DataType="examplenamespace:IEmployee">
        <Grid>
            <TextBlock Text="{x:Bind Name}"/>
        </Grid>
    </DataTemplate>
</ResourceDictionary>
```

C#

```
// TemplatesResourceDictionary.xaml.cs
using Microsoft.UI.Xaml.Data;

namespace ExampleNamespace
{
    public partial class TemplatesResourceDictionary
    {
        public TemplatesResourceDictionary()
        {
            InitializeComponent();
        }
    }
}
```

XAML

```
<!-- MainWindow.xaml -->
<Window x:Class="ExampleNamespace.MainWindow"
    ....
    xmlns:examplenamespace="using:ExampleNamespace">

    <Window.Resources>
        <ResourceDictionary>
            ....
            <ResourceDictionary.MergedDictionaries>
                <examplenamespace:TemplatesResourceDictionary/>
            </ResourceDictionary.MergedDictionaries>
